Four or five days before he had felt a tingling and prickling in the right thigh. Then the scar became more and more painful, and the burning and shooting pains were so great that he had not been able to sleep for two nights. He had eaten nothing for two days, and had not been able to swallow without becoming choked. A glass of water was handed to him, but only after a great effort could he swallow one small sip. An intense and suffocating pharyngeal contraction occurred at subsequent attempts.

He was visibly nervous and anxious, and though no mention was made either by him or by me that his symptoms were in any manner connected with the bite, he later confessed that he was so sure he had hydrophobia that he had not dared ask the question lest I should confirm his suspicions.

He was urged to enter the City Hospital at once for treatment, but refused to do this until he could go back to his home. Four hours later he returned, having meanwhile drunk in saloons as much straight whisky as he could force down his throat. The fact that most of these "bracers" never got farther than his mouth, but were immediately expelled, was to my mind valuable proof of the genuineness of his difficulty in swallowing. On admission to the hospital he was somewhat exhilarated by an acute alcoholism, but the difficulty in swallowing had increased perceptibly.

The physical examination revealed several red and painful scars on the outer surface of the left thigh. The cicatricial thickening and induration around these scars was pronounced and somewhat in excess of that usually observed in ordinary wounds of equal severity. Otherwise, the examination disclosed no physical abnormality. Temperature, 99.2 F., pulse 102, respiration 24. Reflexes normal.

These symptoms warranted, in our opinion, a diagnosis of hydrophobia, and in consultation with Dr. Ralph Kinsella, resident physician of the City Hospital, it was agreed that he should be given injections of quinin as suggested by Moon.[1] Quinin and urea hydrochlorid was chosen because of its solubility.

Treatment and Result.—At 5 p. m., August 29, 15 grains of quinin and urea hydrochlorid, dissolved in 3 c.c. of salt solution, were administered intravenously. This dose was repeated at 7 p. m., 9 p. m., 11:30 p. m., and on the next day at 9:45 a. m. and 11:30 p. m., making a total of 90 grains within twenty hours. Following the second injection at 7 p. m. the patient said all pain in the thigh and over the area of the bite had disappeared. At 7:30, August 29, he drank without difficulty 6 ounces of milk and an equal amount at 11:30 p. m. At 7 a. m., August 30, he drank 6 ounces of milk, 6 ounces of coffee, and ate two crackers and a slice of bread.

He had, however, spent a very restless night, and on account of a fine tremor and a nervousness which suggested delirium tremens, he was given at 9:30 a. m. 4 drams of paraldehyd, and an equal amount at 1:30 p. m. He slept at intervals throughout the day and the following night. He had no return of the pains or the difficulty in swallowing and was discharged September 2, four days after his admission.

5. The advantages of ivory plates in transverse fractures are; they fit closely into the fragments; do not loosen up; they are strong enough to withstand any pull made by muscles attached to the fragments; they will not allow angulation, especially if put in at right angles to the greatest tendency of displacement, or, better, at right angles to the greatest pull of the muscles, they will be gradually absorbed, and never act as a foreign body in the bone.

4137 South Halsted Street.

ABSTRACT OF DISCUSSION

Dr. F. J. Cotton, Boston: The first of those plates did not show an osteoblastic absorption, but, rather, a granulation absorption.

Dr. Paul B. Magnuson, Chicago: This plate was practically translucent when I took it out. In six weeks it had softened so much from the absorption of fluids and become tightened into the bone so firmly that it was difficult to get it out. It is eroded at both ends, but little in the middle, at the seat of the fracture. It was just outside the seat of fracture that the greatest erosion took place.

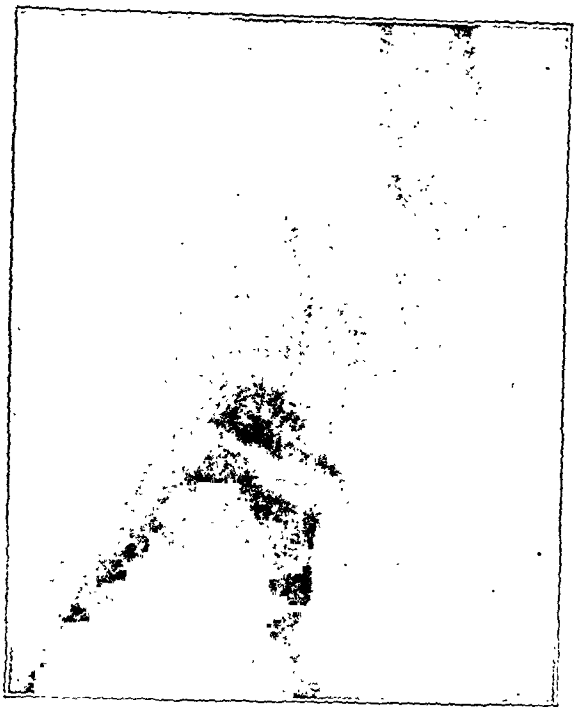

Fig. 8.—Fracture of both bones of the leg.

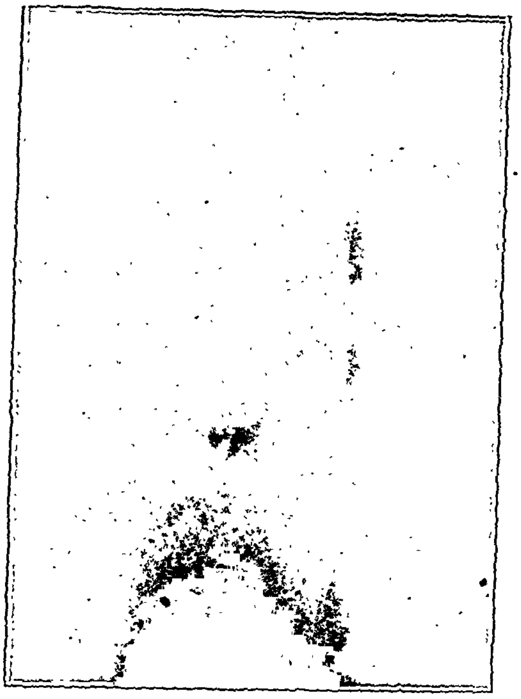

Fig. 9.—Same as Fig. 8, one day after operation. Ivory plate in tibia. Pegs seen as faint shadows on each side of fracture.

Dr. D. B. Phemister, Chicago: Most of the osteoclasts producing absorption of dead bone or ivory are not giant cells, but the ordinary fibroblasts. In my histologic work I have observed extensive lacunar absorption where giant cells were entirely absent.

Dr. John Prentiss Lord, Omaha, Neb.: I should like to have Dr. Magnuson tell us whether he does not think that such work as this would be likely to be undone, unless there is some apparatus for holding the plate securely until the final dressing is applied. It seems to me that there is an opportunity for caution against undertaking to do this work without a fixation apparatus; otherwise I should think that the screws would break in inexpert hands.

Dr. Fred H. Albee, New York: Last year, in the Surgical Section of the American Medical Association, and in the American Orthopedic Association, I reported a scheme similar to this for holding ivory. I have applied it to the femur and other bones, and have had no trouble with breaking of the bone. I have used it as a bone-graft larger in size than this ivory plate; but the bone-plate is in there in an efficient manner mechanically, I believe. Dovetailed, as it is, it holds the fragments efficiently.

Dr. Paul B. Magnuson, Chicago: I agree with Dr. Albee that a live bone-graft is the *ideal* substance. I doubt that it is tolerated by the tissues better, *but it is more stimulating* to the growth of bone than anything else. Unfortunately, we cannot always get a piece of bone to fit accurately. We must do two operations; and few of us are skilful enough to fit a piece of bone into a slot. *It requires great experience in this line of work.* This operation was designed for the use of the average man doing bone surgery, so that he cannot possibly make a mistake. *All that has to be done is to* cut exactly the width *of the space* he wishes to fit the plate into with parallel circular saws, joining the ends of these incisions, and then drill two holes exactly the size he needs; he then has a plate that fits the slot exactly. After the two holes are drilled, put in the ivory pegs at an angle to the plate through *both sides of the bone.* The procedure is mechanically accurate. *The ivory would not, of course, hold on the outside of the bone, because it is not strong enough; but when it is braced by the cortex on each side it will hold, because it is mechanically correct.*

As to Dr. Lord's remark about handling a fracture carefully, of course, this is my baby and my pet, and we are sometimes prejudiced in favor of our own children. Nevertheless, I have maltreated these plates before sewing up the wound, purposely, in order to see whether or not I could pull them loose. I would rather have them come loose at that time than after the patient has gone back to bed, and therefore have taken particular pains to try to break them beforehand; when I put the patients back to bed, I feel sure that the plate will hold its position until the extension apparatus, or whatever I use, is taken off. I have never had the pegs break. There is practically no strain on them. They are put through the upper side of the cortex and there is no leverage to snap them off. If we had leverage, that might happen.

A DISCUSSION OF VARIOUS ANESTHETICS AND METHODS

EXPERIMENTAL OBSERVATIONS *

BERNARD FRANCIS McGRATH, M.D.
ROCHESTER, MINN.

The purpose of this paper is, first, briefly to discuss the present status of the question of anesthetics, secondly, to contribute data from the Mayo Clinic, and, lastly, to present some preliminary observations on an experimental work which is to be continued at length.

A stimulus has recently been applied to the question of anesthesia, which has resulted in a wide-spread interest and in laudable endeavors toward advancement. New anesthetics and various combinations have been employed, apparatus aiming at accuracy has been designed and different routes of administration have been practiced. Commendable and seemingly progressive as are all these efforts, still does not their multiplicity itself emphasize the general state of inefficiency that exists?

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

* From the Mayo Clinic.

To enumerate and describe the several anesthetics, devices and methods which have been advanced would be an unnecessary repetition, since their details are already known, or at least are easily available in the literature. Each has enthusiastic advocates, but which can withstand the test of time?

It has been authoritatively stated that any of the recognized anesthetics or methods is safe in the hands of an expert anesthetist. In an endeavor to place this phase of surgery on an efficient basis should we not begin by investigating the undermost stones in the foundation? In analyzing these is not the administrator of the anesthetic one of the first to attract our attention? Embodied in the expert are those qualities which are essential for the successful production of anesthesia. He guards against the use of anesthetics which contain impurities; his extensive experience frequently enables him to obviate deleterious psychic conditions preceding the operation; his skill in administering ameliorates the mental and physical disturbances of the initial stages of anesthesia; he avoids the recognized nocuous effects caused by vacillation between a light and deep state, and finally, the expert administers the anesthetic only in amount sufficient for the conditions, thereby reducing to the minimum immediate postanesthetic and remote organic effects.

Crile speaks of "two great classes of association, namely, those that are injurious and those that are beneficial. The injurious kind are called 'noci-association,' that is, nocuous or injurious associations." Crile's scientific defense of his theory, together with his and others' observations of its practical application, is sufficiently convincing to demand serious consideration and a general effort to test its soundness.

Although extrinsic to the patient, yet seemingly comprehended in this principle, are certain other "noci-associations" which, until recently, were nearly omnipresent in the hospitals of this country, and even to-day exist to a culpable degree. I refer to the inexperienced house-officer as the official anesthetist of the hospital, and the indirect detriment which results to the patient through the mental disturbance, and, in consequence, the curtailed efficiency of the operator. The chain of asepsis may be intact, the surgical assistants adequately equipped with skill and discipline, and the surgeon most able; but, with the patient at one period rigid and practically inoperable, the next period assuming an ante-mortem aspect, the operator must necessarily be incapable of his best effort. Therein an injustice has been done, since the benefit to the patient, if the anesthetist be excepted, is not commensurate with the pathologic condition which he presents and the efficiency of his environments.

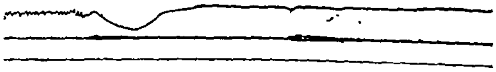

Fig. 1.—No. 635 a. Intravenous ether, 5 per cent. First part of tracing, no anesthesia. Note the result of careful induction and maintenance of anesthesia. Duration one and one-half hours.

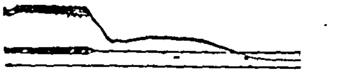

Fig. 5.—No. 615. Intravenous ether, 5 per cent. Showing effect of overdose—"full flow," thirty seconds (190 c.c. solution; ether, 9.5 c.c.). Note continuance of cardiac action (upper line) for about four minutes after cessation of respirations.

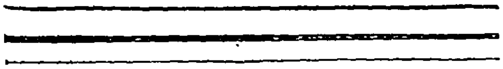

Fig. 2.—No. 635 b. Tracing made at the end of one hour, surgical anesthesia, intravenous ether, 5 per cent.

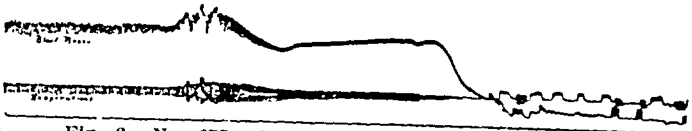

Fig. 6.—No. 675. Intravenous ether, 5 per cent. First part of tracing, local anesthesia. Note effect of accidental overdose and ineffectual efforts at resuscitation. Total solution, 450 c.c.; ether, 22.5 c.c. Time, six minutes.

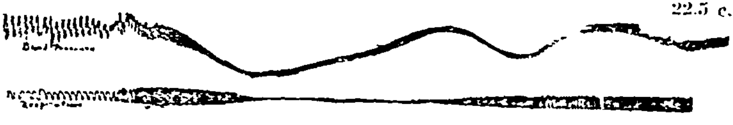

Fig. 3.—No. 681. Intravenous ether, 5 per cent. First part of tracing, local anesthesia. Note early effects of anesthetic on cardiac action and respirations and relation of respiratory failure to effect on heart. Spontaneous recovery.

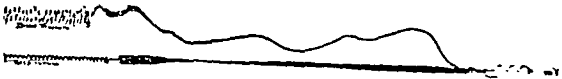

Fig. 7.—No. 672. Intravenous ether, 5 per cent. First part of tracing, no anesthesia. Note induction of anesthesia, practically synchronous cardiac and respiratory failures and ineffectual efforts at resuscitation. Total solution, 300 c.c.; ether, 15 c.c.

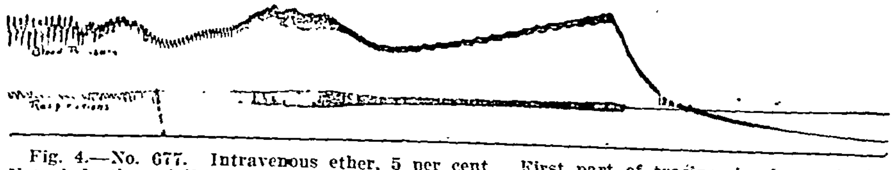

Fig. 4.—No. 677. Intravenous ether, 5 per cent. First part of tracing, local anesthesia. Note induction of light anesthesia in first and second thirds of tracing. In the last third note effect of "full flow" for twenty seconds (solution, 126.60 c.c., ether, 6.30 c.c.). No recovery. Heart failed about two minutes after cessation of respirations.

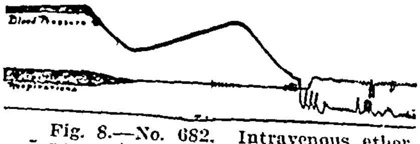

Fig. 8.—No. 682. Intravenous ether, 5 per cent. Note relation of respiratory to cardiac failure and the ineffectual efforts at resuscitation, when artificial respiration, heart-massage and abdominal pressure were begun late. Total solution, 350 c.c.; ether, 17.5 c.c.

The best anesthetic administered by the most expert anesthetist would be the ideal in anesthesia. Such an ideal condition is no more feasible than that every surgical operation be performed with the best technic by the most skilful surgeon. The reasons are obvious. That the expert anesthetist is not now and never will be generally available is self-evident, but that there is a vast territory of the medical field in which such idealism could and should be applied the most skeptical will not deny.

It is but truth to state that medical schools in general have not adequately taught and emphasized this seriously important branch of medicine. In many instances men are graduated with little theoretical and far less practical knowledge of the subject. Just as the student with a bent toward surgery, pathology or any of the other branches of medicine should be encouraged and scientifically trained in that direction, so, too, should the one adapted to the work of anesthesia be similarly encouraged and guided.

One has but to scan the statistical history of anesthesia to note the wide divergence of results. This diversity seems to be due primarily to a lack of parallelism of all the factors concerned. Some of the obviously essential factors in estimating the comparative value of anesthetics and methods are the purity of the drugs, the skilfulness of the anesthetist, a reasonable parallelism in the number of cases observed and the condition of the patients.

The comparative value of the anesthetics more recently advanced and the methods of administering them are at present and for some time must remain in the balance.

It is easily conceivable that some of the more recently advocated methods of inducing anesthesia are positively indicated in some operative procedures, and at least helpful toward efficiency in others. This is particularly true when applied to operations about the head and neck and within the thorax. In this regard the methods of Crile, Meltzer and Auer and others are particularly applicable. The indications for the intravenous administration of anesthetics seem at present to be very limited, although time and research may radically alter this view.

In making a wide survey of the field of surgical achievements, including statistical history, supplemented by the opinions of keen and progressive observers, no other anesthetic or method for application in general is so soundly supported by *time and experience* as ether administered by an expert, with a due allowance of air to the patient. Compared with other anesthetics and methods, ether by the so-called "drop" method is at least as immediately safe, is more available, more economic, and more conducive to efficiency in extensive work. I am not cognizant of data sufficiently reliable and extensive to prove that in the hands of the skilful, the immediate deleterious effect on the condition and comfort of the patient, and the remote effect on the organs of the body are more than those of any other anesthetic or method.

The advancement which is being made in the application of local anesthetics augurs well for substantial aid to surgery along these *lines and this* affords a most fertile field for research. General anesthesia is at best a *fairly* wide deviation from the normal, but, in the present state of our knowledge, is absolutely indicated in many cases. With the scientific advancement of local anesthesia, we may hope to see the number of indications for general anesthesia reduced to a minimum.

Finally, praiseworthy and seemingly progressive as are the various endeavors which are being made in the application of new general anesthetics and methods, nevertheless it appears that one of the most essential steps, if not, indeed, the most essential step, toward placing the question of anesthesia on an efficient basis is the training and encouragement of the skilled anesthetist.

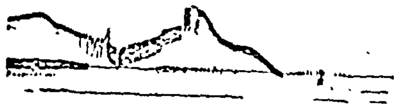

Fig. 9.—No. 683 c. *Intravenous ether, 3 per cent. First third* of tracing shows effects of "overdose"—ether 9.4 c.c. in one minute and epinephrin 3 drops; middle third, temporary signs of recovery, with subsequent failure, despite efforts at resuscitation.

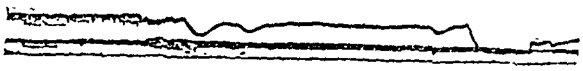

Fig. 10.—No. 673 a. *Intravenous ether, 5 per cent. First part* of tracing, local anesthesia. Note induction in middle third and effect of twenty seconds' full-flow—solution, 126 c.c.; ether, 6.3 c.c.—in last third. Abdominal pressure. Recovery.

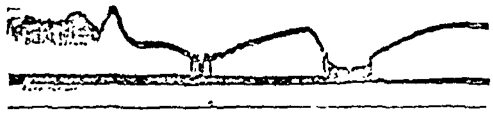

Fig. 11.—No. 633 a. Intravenous ether, 3 per cent. First part of tracing, no anesthesia. Note induction of anesthesia (light). Last of tracing depicts the effects of 30 seconds' "full flow," 4.7 c.c. ether, with spontaneous recovery.

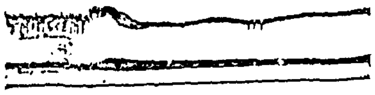

Fig. 12.—No. 688. Inhalation ether, automatic. First part of tracing, no anesthesia. Surgical anesthesia in about two minutes. Note on tracing good result of careful induction and use of air with ether.

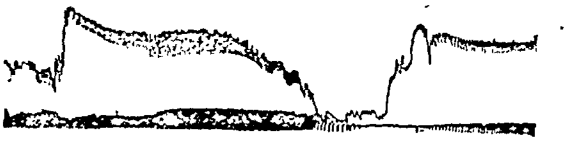

Fig. 13.—No. 319 b. *Inhalation ether, automatic.* Note in middle third of tracing the effect of uneven administration of anesthetic. Upper tracing, cardiac; lower, respiratory. Spontaneous recovery.

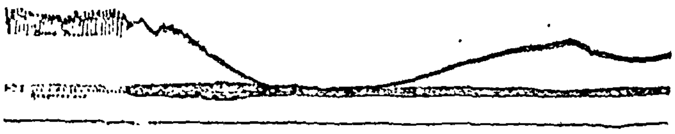

Fig. 14. No. 676. Intravenous chloroform, 1.5 per cent. First part of tracing, local anesthesia. Note effect on cardiac action during induction of anesthesia. Spontaneous return to normal.

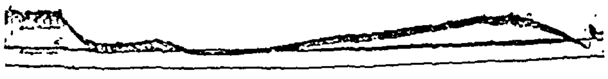

Fig. 15.—No. 657. Intravenous chloroform, 2.5 per cent. First part of tracing, local anesthesia. Total solution, 475 c.c.; chloroform, 11.87 c.c., in eleven minutes. Note cardiac and respiratory failure. Efforts at resuscitation futile.

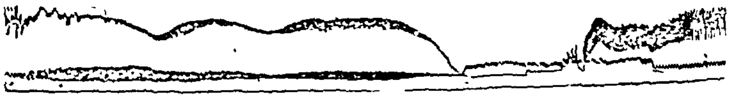

Fig. 16.—No. 621. Intravenous chloroform, 2.5 per cent. Note induction and failure in first and middle third. *Cardiac action* and respirations ceased almost simultaneously. Efforts at resuscitation effectual.

DATA FROM THE MAYO CLINIC

From the year 1900 to the beginning of the present year the respective numbers of general anesthetics administered were as follows: ether, 49,057; chloroform, 1,300; nitrous oxid (usually nitrous oxid-ether sequence), 1,000, and ether-chloroform sequence, 796. The nitrous oxid administrations were made during the years from 1900 to 1904, inclusive. Since 1907 chloroform alone has been employed in one case. The mode of administering ether is the so-termed "drop" method. Besides the before-mentioned, several of the local anesthetics were employed.

No death ascribable to the anesthetic alone has been noted. None of the present anesthetists has even administered a stimulant hypodermically during operation. *Excitement* in the initial stages of anesthesia has been very rarely observed. Postanesthetic effects, such as nausea and vomiting, have been, as a rule, inconsiderable.

PRELIMINARY ADMINISTRATION OF DRUGS

In cases of exophthalmic goiter in which operation was performed without general anesthesia, scopolamin, 1/200 grain, and morphin, 1/6 grain, is used. If a general anesthetic is to be administered, atropin 1/150 grain, is also employed. In operations for ordinary goiter, morphin, 1/6 grain, and atropin, 1/150 grain, are used. In operations on the stomach and rectum, morphin, 1/6 grain, is used. If a patient has had bronchitis or a cold, morphin, 1/6 grain, and atropin, 1/150 grain, is employed. Scopolamin and morphin are administered to quiet nervousness, but apparently as a result increased excitement has been occasionally observed. It is considered probable that following the use of these drugs a smaller amount of the general anesthetic is necessary. In operations on the stomach the preliminary dose of morphin makes it feasible to decrease the amount of general anesthetic during the work in the abdominal cavity. Atropin causes and maintains a dry condition of the upper portion of the respiratory tract and is regarded by the anesthetists as very effective when indicated. Generally speaking, however, ether alone is used, the aforesaid drugs being employed only in exceptional cases under special indications.

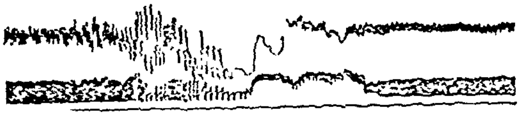

Fig. 17.—No. 217. Inhalation chloroform, automatic. Note primary cardiac and respiratory failure and the effect of prompt artificial respiration by tracheal insufflation. Duration of anesthesia, one hour and four minutes.

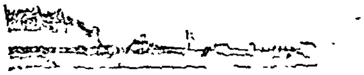

Fig. 18.—No. 687. Inhalation chloroform, automatic. Note early cardiac failure and futile efforts at resuscitation.

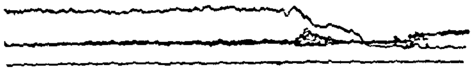

Fig. 19.—No. 634. Intravenous ether, 5 per cent. First and second thirds of tracing, no anesthesia. Last third shows effects of air entering tube during induction of anesthesia—about 100 c.c. air. No recovery, despite efforts at resuscitation. This indicates the danger of a defective apparatus.

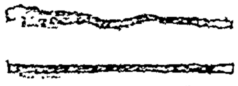

Fig. 20.—No. 683 b. Intravenous ether, 3 per cent. Surgical anesthesia. Tracing shows absence of evil effects when tube to vein is completely severed while solution is flowing.

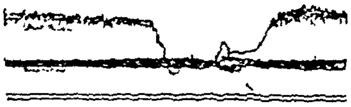

Fig. 21.—No. 665. Local anesthesia. Air-embolism syringe, 60 c.c. air, in fifteen seconds. Spontaneous recovery.

The object aimed at is to guard against impurities in the anesthetic, to induce anesthesia with the least possible mental and physical disturbance of the patient and to employ the smallest amount of anesthetic consonant with an even surgical anesthesia.

As may be gleaned from an analysis of the records, ether by the drop method, in the hands of skilled anesthetists, indicates the position of the Mayo Clinic on the question of general anesthesia. The present tendency of the clinic is toward amplifying the employment of local anesthetics.

EXPERIMENTAL OBSERVATIONS

During the past three months I have been pursuing experimental investigations on the subject of general anesthesia. The work thus far done is admittedly academic, but designedly presented at this stage not so much for discussion of the indefinite results obtained as for criticism of the procedure as a method of studying and teaching the subject. The object in view is to continue the work at length, investigating the various recognized anesthetics and methods, whatever new may be advanced, studying not only immediate but also remote effects on the organism, and prolonging the work in series sufficiently extensive for deductions of practical value.

One hundred and fifty-three experiments have thus far been undertaken on 145 dogs. The anesthetics employed are ether, chloroform, paraldehyd, combined paraldehyd and ether, urethane, and nitrous oxid-oxygen-ether.

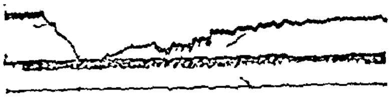

Fig. 22.—No. 408. Intravenous ether, 5 per cent. Note effect of air-embolism—syringe, 100 c.c., air in fractional injections in first part of tracing. Spontaneous recovery. Light anesthesia.

Fig. 23.—No. 649. Intravenous ether, 5 per cent. First part of tracing, local anesthesia. Note induction of anesthesia in first third of tracing, effect of air-embolism, about 60 c.c. slowly, in middle third. Spontaneous recovery, light anesthesia, but sudden cardiac and respiratory failure after a small dose of ether. Unsuccessful efforts at resuscitation.

Fig. 24.—No. 673 b. Intravenous ether. Air-embolism—50 c.c. air in fractional doses, few seconds apart. Compare effect on heart, upper line, with respirations. Spontaneous recovery.

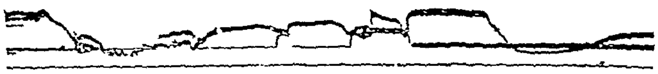

Fig. 25.—No. 646. Intravenous ether, 5 per cent. First part of tracing, local anesthesia. Note early respiratory and later cardiac failure. Efforts at resuscitation successful. Air-embolism, about 70 c.c., slowly injected. Shown in last third of tracing. Spontaneous recovery.

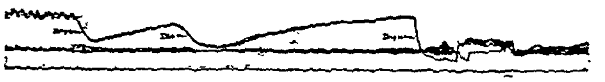

Fig. 26.—No. 637. Intravenous ether, 5 per cent. First part of tracing, local anesthesia. Note cardiac action and respirations during induction of anesthesia. Final third of tracing is a picture resulting from an injection of about 50 c.c. air into femoral vein, tracheal insufflation of air and abdominal pressure. Recovery during light anesthesia.

The methods of administration used are the intravenous, automatic inhalation, insufflation and rectal. Kymographic records of cardiac action and respirations have been constantly made. Owing to the brevity of the time and the extent of the work, the investigation of some of the anesthetics and methods has been too limited for presentation.

Ether has been administered intravenously 85 times, chloroform 19, paraldehyd 2, and combined paraldehyd and ether 3; by the pulmonary route, ether 27 times, and chloroform 8. Besides these experiments, a series of histologic examinations has been begun for the purpose of studying the effects of the various anesthetics on the tissues of the body. An endeavor will be made to make this work as complete as possible, and sufficiently extensive for data of value. Although some excellent observations have been reported on this phase of the subject, still it seems that in general attention has been mainly focused on the immediate deleterious effects of anesthetics, somewhat to the neglect of their remote effects on the organism.

In the present limited series the procedure has been to study immediate effects during the induction of anesthesia, the results of overdosing, uneven administration, anesthetics with probable impurities and the efficacy of various methods for resuscitation applied early and late in cardiac and respiratory failure, such as insufflation, abdominal pressure, heart-massage and stimulating drugs injected directly into the circulation. With local anesthesia it has been practicable to obtain normal tracings of cardiac action and respiration for comparison with the various phases of the tracings which followed.

The intravenous method has been employed 109 times. In normal saline solutions the following strengths of anesthetics have been used: ether, 5 and 3 per cent.; chloroform, 2.5 and 1.5 per cent.; paraldehyd, 2 per cent.; ether, 5 per cent., and paraldehyd 1 per cent. Hedonal and other anesthetics will be added to the list in the further progress of the work, and Ringer's solution will replace the saline solution which has been used.

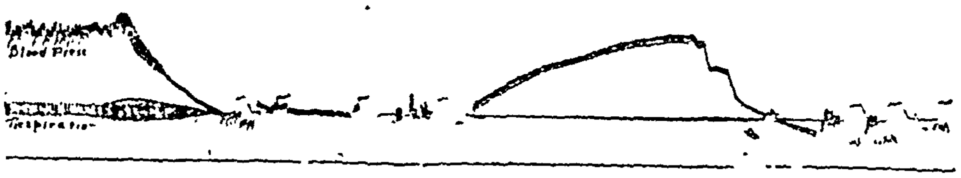

Fig. 27.—No. 678. Intravenous ether, 5 per cent. First part of tracing, local anesthesia. In first third of record note very early cardiac and respiratory failure. In middle third effectual efforts at resuscitation. In last third fatal effect of air-embolism —about 60 c.c. air within twenty seconds Help ineffective.

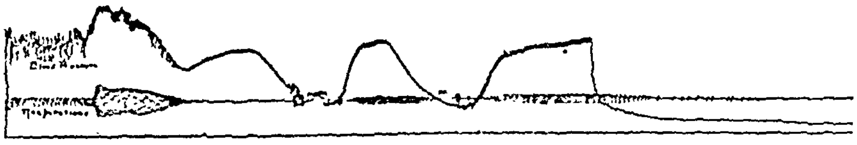

Fig. 28.—No. 674. Intravenous ether, 5 per cent. First part of tracing, no anesthetic. Note primary anesthesia with early respiratory failure and its relation to cardiac failure. Artificial respirations and heart massage; recovery and again failure on adding small amount of ether. Recovery with help. Air-embolism—60 c.c.—syringe. Sudden and fatal cardiac failure. Slight spontaneous efforts at respiration toward end.

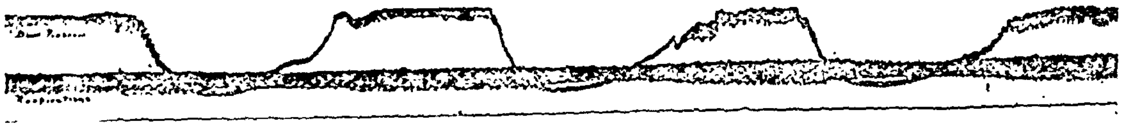

Fig. 29.—No. 680. Inhalation ether, automatic. Light anesthesia. Total amount of air injected into femoral vein, about 300 c.c. First drop is effect of 100 c.c. air in twenty seconds, second and third drops, 100 c.c. in fifteen seconds each. Note that respirations are little affected. Recovery, but animal died two days later. Air in heart and quite generally in veins.

AIR EMBOLISM

The question of air embolism has been studied in association with the experiments on intravenous anesthesia. This has consisted of the injection into the femoral vein of large amounts of air, from about 50 to 100 c.c. at once, and large amounts fractionally. Observations on the effects of air embolism have been made with local, light and deep general anesthesia.

As previously intimated, the results of experimentation will not be discussed at this time. A clearer idea of the plan of the work is better seen depicted on the limited number of the accompanying kymographic records.

ABSTRACT OF DISCUSSION

Dr. Torald Sollmann, Cleveland: The paper has helped to confirm some conclusions I had formed on this subject. Any anesthesia is a departure from the normal. For that reason it is impossible to expect that we shall ever find a "fool-proof" anesthetic. The improvements that are needed are in intelligent use. With intelligent use the present anesthetics will suffice to produce relatively safe anesthesia. The safety is proportional to the intelligence with which the anesthetic is administered. For intelligent administration as many positive data as possible are necessary and the present investigation helps to this end.

Dr. Alexander S. von Mansfelde, Ashland, Neb.: I have perhaps been placed most happily in my work in surgery, for the reason that I had an unusually fine anesthetist, my wife, who gave chloroform for me for thirty years. I never for a moment had to think of my anesthesia when I operated. Three times in my career it has happened to me that my patients came near dying, although only one of them gave me a great deal of work. Some of you who are informed on anesthesia know of the report of the Hyderabad Commission in England. The essence of that great piece of work seems to have been that it was a difference in the temperature, of moisture and warmth, that made the commission endorse chloroform above all other anesthetics. After reading that report carefully, I concluded that I would try out the work of that commission and I made what is called in physics a moteless chamber of my operating-room. I superheated it a short time before the operation and had it intensely moist and let it come down to a temperature of 103 or 104 F. and kept it there. Remarkable as it may appear, I had no shock in severe abdominal operations when the temperature was from 103 to 104 F. I never, under any circumstances, had the bad results which are said to accompany anesthesia, and that was because the anesthetist gave medicinal and not poisonous doses of the chloroform. You cannot conceive the necessities that come to the surgeon as they came to me in the early history of the state of Nebraska, where I had to be everything and do everything in an operation, many times under conditions and circumstances that you will think abominable. Yet I lost no one from chloroform anesthesia. Now who would be able to go and do a rather lengthy and severe piece of surgery with absolutely no assistant whatever except the farmer's wife or daughter picked up for the occasion? Who of you would undertake to perform a difficult and lengthy operation with ether with an inexpert person to give it?

Try it and see what you think of it. With chloroform I could watch the giver; I could not with ether. I would emphasize again the fact that medicinal doses of chloroform are perfectly safe. I removed an ovarian tumor and my wife gave just 2 drams of chloroform during the whole operation. I did the operation in just nineteen minutes. The point I make is that the surroundings of the case are most important. The atmosphere, if it can be brought to the condition of the Hyderabad temperature and climate, will produce the same effect on the use of the chloroform here as it had there. The sum total of it is that someone who knows how should give chloroform in the best possible surroundings and never beyond a medicinal dose.

Dr. Clyde Brooks, Pittsburgh, Pa.: In regard to the method of giving anesthetics I would speak of a method we used in giving it to animals. I found that valves produced more or less resistance and partial asphyxia.

In the method I have employed there is a cannula inserted into the trachea, with side opening with a rubber connection with a screw-clip for regulating depth of anesthesia. Next there is a side-tube which dips under oil or some such liquid which forms a liquid valve to allow outflow but prevent inflow. Next there is a tube that dips under the ether in the ether bottle and forms a liquid valve which allows inflow, but not outflow. During inspiration the air would flow through the liquid-ether valve, and into the lungs of the dog, whereas during expiration the ether-liquid valve would close and the expired air would flow out through the oil-liquid valve. This offers slight resistance and, in fact, the least resistance of any method that I have employed.

Dr. McGrath alluded to "the Meltzer insufflation method." I would ask whether he was under the impression that Dr. Meltzer originated the essential points in the method employed by Dr. McGrath? Some have maintained that Meltzer's name should not be used to designate the method.

Dr. B. F. McGrath, Rochester, Minn.: In applying the name "Meltzer" to the method of insufflation, I did not have the question of priority in mind. To say the least, the investigations of Meltzer and Auer have added a stimulus to and amplified the application of this principle.

THE RELATION OF POLITICS TO THE STATE CARE OF CRIPPLED AND DEFORMED *

H. WINNETT ORR, M.D.
Superintendent and Assistant Surgeon Nebraska Orthopedic Hospital
LINCOLN, NEB.

It affords me much pleasure to read, in Minnesota, a paper on the relation of politics to the state care of the crippled and deformed, for it was the first of the United States to provide state care for these patients. The whole modern movement, which has for its motive the prevention of dependency, finds no better expression than along the line which aims to convert deformed or crippled children into independent and self-supporting persons. Many of the physical infirmities which these patients have are not susceptible of complete cure, but a considerable majority of all persons so affected may, by suitable surgical and mechanical treatment and by especially adapted methods of education, be rendered capable of self-support.

There are many reasons why the care and education of crippled children is naturally a state function. It has long been considered that the education and training of normal persons is a profitable thing for cities and states to do, but it is certain that a much larger proportion of those who are crippled become dependent if not made the object of special care. Economically therefore the state is simply using ordinary business foresight if by suitable hospital care and education these patients are treated and trained so as to become partially or wholly independent and self-supporting.

It has long been recognized that special institutions are necessary both for the hospital care of crippled children and for the education of those who are defective either physically or mentally. To me it has seemed for a long time that the combination into one institution of the hospital and school for crippled children is of special importance. We have found in the Nebraska Orthopedic Hospital that considerable progress educationally may be made by these patients while actually under treatment. Moreover, a continuation of their educational training and the selection of occupations for them is probably more successfully done under the supervision of those who have administered their hospital care and who have a full appreciation of the physical and mental needs and qualifications of these patients.

The question has frequently been raised in Nebraska and elsewhere as to the propriety of having the affairs of an institution of this character administered by politicians. After eight years of experience in a state institution, during which time our appropriations have been obtained directly from the state legislature, our affairs ordered by legislative committees, and administered by state officers, it may be well to give some public expression of the manner of origin and development of this important work.

In the Nebraska legislature of 1904 a few persons (not more than six or eight), including Mr. J. H. Casebeer, who was a member of the legislature at that time, prepared and had introduced a measure providing for an appropriation of $25,000 to establish and maintain for two years an institution for the hospital care and education of the crippled and deformed. This original bill was modeled after the Minnesota law, except that the institution was placed in the custody of the board of lands and buildings instead of under the regents of the university. The Nebraska bill contemplated, however, that as in Minnesota, the matter of the appointment of officers should be in the hands of a board rather than that it should be left to the governor alone. The Orthopedic Hospital was the first institution in Nebraska for which this provision was made. Practically every member of the legislature of 1904 was duly presented with arguments in favor of inaugurating this work, and eventually the bill passed both branches of the legislature practically without opposition except that the amount of the appropriation was reduced from $25,000 to $10,000. On the presentation of the bill to the governor for his signature, however, the question was raised as to the actual necessity for such an institution. Governor Mickey expressed the belief that the number of patients actually in need of such care in Nebraska must be very small. A comparative estimate based on the number of cripples in other localities led to the conclusion that there must be as many as twelve or fifteen hundred in Nebraska. The final argument which induced Governor Mickey to sign the bill, however, was the collection by Mr. John Davis, then secretary of the board of charities, of information regarding about seventy-five cripples who were at that time objects of public care at county poor-farms or otherwise. On this showing being made, Governor Mickey signed the bill and it became a law.

The Nebraska Orthopedic Hospital was opened for the reception of patients Oct. 1, 1905, and our first official biennium closed Nov. 30, 1906. During the fourteen months 108 patients had been received at the institution. The next legislature, before whom an accurate showing was made, not only of the work already accomplished, but of the patients then in the institution and of other candidates for admission for whom no facilities had been provided, responded at once with an emergency appropriation for immediate use and with a much larger appropriation for the succeeding biennium, the total amount being in the neighborhood of $50,000. Of this amount about $20,000 was spent in remodeling our building so that it became much more satisfactory for hospital purposes.

During a period comprising nearly four years, the experiment of caring for the crippled children of

Nebraska was actually worked out. Adequate provision was made for hospital care and for the beginning of our educational work. Much of the credit for what was accomplished during this time must be given to Mr. H. M. Eaton, chairman of the board of public lands and buildings, who had for many years prior to his election to this office been associated with the public and normal schools of this state. Mr. Eaton was, and has always been since, very enthusiastic in his support of this work. He was ably seconded in his efforts by Mr. A. Galusha and by Mr. Geo. C. Junkin, who were successively secretaries of state, Mr. Peter Mortensen and Mr. L. G. Brian, state treasurers, and Mr. Norris Brown, since United States senator from Nebraska, who was attorney general. Except for the intelligent sympathy and the enthusiasm of these men, the initial success and development of our institution would have been impossible even with the appropriations made for our work.

The legislature in 1909 by appropriating $40,000 made adequate provision for the maintenance of the institution for the next two years. No provision was made at that time, however, for any extension of our buildings, so that no considerable amount of expansion was possible. Since 1909, however, when we had an average number of patients of less than fifty, our growth has been very rapid. An appropriation of $90,000 in 1911 for the next two years and a total of $152,000 in 1913 by the legislature which has just adjourned affords some idea of the growing appreciation on the part of the members of the legislature of the work already accomplished and of its possibilities for the future.

The chairmen of the finance committees in both the senate and the house this year gave especially careful consideration to the requirements of our institution, especially Senator W. H. Reynolds, who made several personal visits to the institution and conducted an investigation into the affairs and requirements of the institution, the results of which were chiefly responsible for the appropriation of $45,000 for a new fire-proof building to be added to our equipment.

Mr. G. W. Potts, chairman of the finance committee in the house, was similarly disposed to make adequate provision for our needs and our improvements.

One of the principal matters before the legislature during this session was the passage of a law to establish and regulate the affairs of a new board of commissioners for state institutions. This new board was provided for by a constitutional amendment adopted by the people of the state about two years ago. In the present legislature legal provision was made for the organization, powers and duties of this new board. Gov. John H. Morehead has also carried out the intent of the law by the appointment of Ex-Gov. Silas A. Holcomb, Mr. Howard A. Kennedy and Mr. Henry Gerdes, so that a non-partisan board of commissioners is now at the head and in charge of all state institutions, including the Nebraska Orthopedic Hospital.

We now have at all times more than one hundred patients in the institution (this is the limit of our capacity), and with our new building under way our capacity will be about one hundred and sixty. Increasing provision has also been made for our educational work, the object being to provide training particularly along industrial lines. Most of our instruction is of the individual kind and for the past three years our school has been in operation for twelve months in the year.

The epidemic of infantile paralysis in Nebraska in 1909, which gave us nearly one thousand more crippled children, has been a determining factor in the development of our work. We estimate that there are at present in our state between two and three thousand children who could be benefited or entirely cured and their education greatly facilitated by the methods employed in the Nebraska Orthopedic Hospital.

From these figures it is easy to infer something as to the situation in other states. Minnesota, through Dr. Gillette, was doing fine work along this line before Nebraska began. New York had also already established an institution for the state care of crippled children. Massachusettes since that time has built and is operating a great educational plant for its cripples. In all of the other states, however, this field is practically undeveloped. A few states like New York, Illinois, Maryland, Pennsylvania and Maine are doing magnificent work through contributions of private philanthropists, with or without state assistance. There is great need, however, for the awakening of the public conscience with regard to these patients. We have become prodigal in our expenditures for the education and training of normal children, while those most in need of special care and training are allowed by reason of neglect to drift further into a state of dependency.

The point to which I wish to call particular attention is that in some states, perhaps in many, no special effort has been made in this direction because of the fact that those who are most interested have expressed themselves as unwilling to "mix in politics," as they express it, or to resort to political methods to secure the appropriations to establish these necessary special institutions.

The lesson we have learned in Nebraska is that our members of the legislature and our state officers have been our best friends; that they have been quick to appreciate the possibilities of this work as well as the needs of the patients and that without their sympathy and support in this, as in any other public work, success would have been absolutely impossible.

First National Bank Building.

ABSTRACT OF DISCUSSION

Dr. J. W. Cokenower, Des Moines, Iowa: I should like to add to the list of states that have made provision along this line the state of Iowa. Last winter I wrote to Dr. Arthur J. Gillette of St. Paul for a copy of the Minnesota law regarding the matter. I wanted to prepare a similar bill to present to the legislature of Iowa, and was supported by the State Board of Control. While I did not obtain so large an appropriation as I wanted, yet I obtained a small one which is in the hands of the State Board of Control, who are in touch with the cases in the state that need aid. I believe that at the next session of our legislature we shall be able to pass a bill providing for a state hospital for the care of these cases. I have been talking with some of the members present and find that there are two other states that are going to join us; so I think that state institutions for the care of crippled and deformed children have come to stay and that it will not be many years before nearly all states will have established hospitals for the care of indigent crippled and deformed children.

Dr. Emil S. Geist, Minneapolis: Minnesota is one of the first states in which this work was done, all through the efforts of Dr. Gillette. The buildings of the State Institute for Crippled and Deformed Children testify that the Minnesota legislature is good to these children. An additional grant of sixty thousand dollars has been allowed to enlarg our state institution, which, by the way, has been moved from the St. Paul City Hospital to the environs of St. Paul, where open-air methods can be pursued more successfully.

Dr. Gilbert L. Bailey, Oak Park, Ill.: It has been my good fortune to go through the school for cripples at Munich, Bavaria, which is supported partly by voluntary contributions and partly by payments made by the different towns sending crippled children to it. A town sending a crippled child to this institution pays sixty dollars a year for the four or five years required to prepare the child for the work he is most capable of doing, and in the practical German method it has been found that this sixty dollars a year is trifling compared with the cost of letting the cripple grow up in ignorance to beg or become a public charge in an almshouse. This dollars-and-cents view may also impress our politicians and the public of the advisability of establishing such schools here.

One of the troubles in the existing schools is that the child is dropped too early. In Chicago we have the public grammar schools for crippled children, who are conveyed to and from school in busses at the public expense and receive as much of a primary education as they can take, after which they are left to shift for themselves. Without a special training for the arts, crafts or business, they rarely find employment on account of their physical handicaps and, therefore, lead the lives of mendicants, or objects of state or private charity. At relatively slight cost, schools could be established, like that in Munich, which would take the cripple at the age of 14 or thereabouts and in four or five years teach him one of the arts, crafts or business methods, which would make him a self-respecting member of society, instead of a helpless dependent on charity.

Dr. John Joseph Nutt, New York: I know about the work of interesting the politicians in these hospitals. This year we obtained an appropriation of sixty thousand dollars to put up new buildings and $32,500 for maintenance.

One point that will make it a little easier for anyone trying to induce the legislature to give money for the care of crippled children is a proposition that making such provision will be economical for the state in the end. There is little hope of being able to return feeble-minded children to their homes, the chances being that they will have to stay in institutions for the rest of their lives. It is different with the crippled children. They become useful citizens. The return to the state for its investment in the hospital is absolutely demonstrable. There is a great deal done in New York City in the way of special schools for crippled children. They receive, however, only such surgical care as is afforded in the dispensary or by a visiting physician and their home life is never suitable for one suffering with tuberculous arthritis. Continuous hospital treatment until cured, with scholastic and industrial training, is what we are offering at the New York State Hospital for Crippled and Deformed Children.

Dr. John Prentiss Lord, Omaha, Neb.: Dr. Orr lives in the capital city, where the hospital is, and has taken pains to show these men the work that is being done there and to impress on them the need of it. Doctors are likely to have prejudiced ideas about legislators and their motives and the way in which they carry out their legislative functions. These men do the best they can, and it is largely a matter of determining the greatest needs in deciding the matter of the distribution of the money to the best advantage according to their way of thinking. It has been apparent that these men, on being shown this work and its necessity, have been most willing to cooperate with us. That is the secret of the whole thing. When doctors undertake to secure these appropriations, they ordinarily go to the capital with their demands and make their statements offhand, and any opposition is resented. If they would show the legislators the need of these appropriations, I think that it would be as easy to conclude the matter successfully in other states as it has been in our state through the efforts of Dr. Orr. That was all that was required to secure these increasing appropriations for this work, and I wish to acknowledge the credit that is due to Dr. Orr for the efforts he has made, largely single-handed, which have resulted in securing appropriations for the maintenance and upbuilding of the Nebraska State Orthopedic Hospital.

Dr. Albert H. Freiberg, Cincinnati: Some efforts have been made to establish a state hospital for the crippled and deformed in Ohio. I have heard nothing and seen nothing, thus far, to convince me that, as a general proposition, a state hospital is a good thing. It may be in some states, and possibly those states in which the greatest success has attended the efforts to secure it are the ones for which the plan is best adapted. My idea was to have a commission for the care of the crippled and deformed, and to have them treated in institutions already existing, instead of having each state build an institution for this particular purpose, taking children from one part of the state to another, in order that they might get the necessary treatment. I think that the question of schools is a different proposition altogether; but I doubt that it is right to have a school situated in one part of the state, and to take children to it from other parts of the state to be cared for.

Dr. Lord has not succeeded in convincing me of the ease with which these things can be obtained politically, because we have had evidence of rather strenuous attempts on the part of the doctors there to convince their legislators that orthopedic cases should be treated by men who know something about orthopedics. Indeed, they sought some evidence in regard to this necessity from us. My feeling is that, in the United States, as in Europe, there are men who busy themselves especially with these problems, and that it should be the duty of the state to take the children to these men; that a state commission should exist, to whom these persons should be brought, and that the commission should see that the children are placed where they can obtain proper treatment, without requiring them to be taken several hundred miles from their parents while they receive a long course of treatment and schooling, adapted to their particular crippled condition.

Dr. H. Winnett Orr, Lincoln, Neb.: Dr. Freiberg has put his finger on the sensitive spot, but I consider that his criticism is just and fair. My contention is, however, that a physician who wants to accomplish things along these lines must, on that account, familiarize himself with the methods that politicians use and adopt their methods, so far as is proper and right.

In regard to the matter of institutionalizing these children, I would say that this is a point raised by many members of the medical profession and others. I am in sympathy with this argument in dealing with normal children; but there are few cripples, especially those who have active disease also, who are not better off in institutions than they would be at home with their parents. The parents and the family physicians rarely do justice to these children; and a special institution, with a special staff and organization, and especially, special educational opportunities and facilities, is absolutely essential if we are to give these children a chance.

Dr. A. J. Gillette, St. Paul, Minn.: This is a matter that ought to come before every single state in the Union in which there is not a hospital for orthopedic work in which the patients may be left as long as necessary. Another point is that it is a great deal easier to establish one of these institutions in a state than is supposed. I do not believe that there would be trouble in going to any legislature and getting some men interested in it, by teaching them what you mean by orthopedics and what you purpose to do. I should like to say that it would be all right to state in introducing a bill of this kind that the doctor is to receive no salary. It is right for him to have a salary later; but if you ask for a salary at first, you will have trouble in securing the passage of the bill. A good plan would be to limit the time during which the physician shall serve without a salary to the first five years.

Dr. H. Winnett Orr, Lincoln, Neb.: I should like to have Dr. Gillette discuss a question which Dr. Freiberg has raised by saying that he thought that it would be better to have the crippled children under the care of a commission in local hospitals, wherever they happened to be, than to have them placed in a special institution.

Dr. Arthur J. Gillette, St. Paul, Minn.: Judging from the conditions in Wisconsin, where I had something to do with getting an appropriation since I had a personal friend in that legislature, I should say that the scheme for the appointment of such a commission would be a failure. In that state, such an arrangement is almost an absolute failure. I think that these children should be placed togther in a hospital, to be taken care of by persons who are educated in caring for cases of this kind.

THE ORTHOPEDIC SURGERY OF FIFTY YEARS AGO WITH SOME REMINISCENCES AND CONCLUSIONS *

NEWTON M. SHAFFER, M.D.
NEW YORK

The present occasion is not only one which calls for congratulation and felicitation to those of us who have labored for years for the advancement of orthopedic surgery, but it may also be regarded as being, in some important respects, the semicentennial of the birth of this important branch of surgical science. It seems, therefore, a proper occasion to refer to the stirring events of fifty years ago which marked the strenuous activities of such men as Davis, Taylor, Sayre and Knight, whose genius and abilities have made possible the development of the orthopedic surgery of to-day, and whose contributions to surgery have, among other important events, resulted in the formation of this important Section of the American Medical Association.

Fifty years ago, May 1, 1863, the New York Hospital for the Relief of the Ruptured and Crippled, opened its doors for the treatment of patients at 97 Second Avenue, under the administration of Dr. James Knight, its founder. It so happened that I was present on that occasion—a humble, but paid officer of the institution, with stated dispensary and hospital duties—and was also the student of Dr. Knight. The opening of this hospital was a notable event in the history of the treatment of the deforming diseases of childhood. It has been followed by many other institutions of a similar nature during the past fifty years, but this was the first duly incorporated institution in this country devoted to this special object.

The establishment of this hospital, especially when coupled with the activities of Taylor and Sayre, made an epoch in the medical history of this country, and brought about a revolution in the treatment of deformities. The year 1863 was particularly prolific in events. Davis had given to the profession his traction apparatus for hip-joint disease, and other valuable appliances, and had formulated his views and principles. Taylor had introduced his ingenious and effectual "spinal assistant" and many other valuable and original devices, and had amplified, in many essential respects, the traction apparatus of Davis, giving us the first available portative traction hip-splint. Sayre brought his great abilities into play and promulgated several important and useful methods, including apparatus for club-foot, and the knee and ankle traction-splints which bear his name. These two men, both born leaders, earnest, energetic, and progressive, led the way. The discussions which attended and followed the development of these new ideas and methods were enlivened by spirited utterances and lively debates. But it all brought about a condition of affairs in which a much neglected branch of surgical endeavor received strenuous attention, and the original work of these pioneers, even at that time, was rewarded by eminent notice both at home and abroad.

The conservatism of Dr. Knight in 1863 and later in refusing to adopt these modern methods in the Hospital for the Ruptured and Crippled led, in 1866, to the establishment by Theodore Roosevelt, Senior, and Howard Potter, under Dr. Charles Fayette Taylor and Dr. John T. Metcalfe, of the New York Orthopedic Dispensary, which was afterwards enlarged and made a fully equipped hospital. Later on, in 1872, the methods pursued in the Orthopedic Hospital were, through the same influences, introduced into St. Luke's Hospital, and I was at that time appointed as orthopedic surgeon to this institution, the first appointment of its kind. Sayre, as professor of orthopedic surgery in Bellevue Hospital, was doing a yeoman's work in the early sixties and his clinics were the Mecca of many who were interested in these newly developed methods. These, and other more or less important events clustered about, and followed, the great events of fifty years or so ago, making this period the first stage of an evolution, the present stage of which would surprise these eminent founders if they could witness the great developments which have followed their teachings and efforts of half a century ago.

I spent five and one-half years under Dr. Knight in the Hospital for the Ruptured and Crippled—from May 1, 1863, to Nov. 1, 1868, being the first assistant resident-surgeon of the institution. I was an interested observer of the events which marked the beginning of my professional career, which commenced when I was but 17 years old. Faithful to my preceptor—a partisan, in effect—I, as a boy, looked with distrust on the new methods. But I experienced a shock of surprise and joy when in April, 1871, I was asked to become an assistant surgeon to the New York Orthopedic Dispensary, and saw the methods there used. Taylor's methods of diagnosis, his alert adaptation of mechanical means to pathologic ends, his great originality in devising apparatus for all kinds of deforming diseases and conditions; his quick appreciation and interpretation of symptoms, all this was a revelation. I became an active follower of Taylor and entered into the work before me with all the zeal I possessed, and soon acquired, or one might almost say inherited, some of the combative qualities which marked the men and their discussions of those early days.

At that time operative surgical work was not ignored, but, in the earnest interest of the moment, was relegated to the background. Sayre was as prominent as an operator as he was in advocacy of Davis' methods, and he rather disliked, I think, to be called an orthopedic surgeon. Those who followed Taylor's teaching were more interested in the development of the mechanical field, than in the operative. Taylor's private hospital and the Orthopedic Dispensary were perfected shops. The assistant surgeons did their own work, from measuring the patients for apparatus, making accurate drawings if necessary, to and including its final adjustment. Some of us would go into the shop and make with our own hands some of the simpler forms of apparatus; and a handy work-bench with tools, in the dispensary treatment room, was used by the assistants to make simple repairs and alterations. There were no trained nurses, nor any women attendants, except a sewing-woman, whose duty consisted in keeping in repair any worn-out leather work, and in sewing on bandages. The assistant surgeons were encouraged to develop new mechanical devices. The instrument makers were regarded as phar-

---

* Chairman's address before the section on Orthopedic Surgery of the American Medical Association at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

macists whose sole duty it was to prepare the mechanical prescription, as furnished by the surgeon. The instrument maker never came in contact with the patient, except, perhaps, when, with the apparatus applied to the patient, a verbal order was given him to make alterations which required shop facilities to produce. The adjustment of the spinal braces was all done by the assistant surgical staff, and the adhesive plasters for traction of the hip or knee were applied by them, as were the necessary bandages. The assistant surgeon was held directly responsible for the care of the patients assigned to him. It was interesting, thorough and arduous work. It was well done, and was orthopedic surgery distinctly, as compared with the work of the general surgeon. This was before the antiseptic method of Lister was introduced, but such operations as were indicated—all supplementing the mechanical work—were performed in the dispensary building, or at the patient's home, the after treatment being carried out at the residence of the patient. Several men—since eminent in this branch of surgery—became students of Taylor or Sayre, or both. These men learned orthopedic surgery. It was never a question as to whether a man was an operative surgeon. It was taken for granted that he could, and would, operate if necessary. He was there to learn new methods in diagnosis and treatment, and a year under Taylor and Sayre was a liberal education.

Later, in 1876, when Dr. Taylor resigned from the Orthopedic Hospital and I succeeded him as surgeon-in-chief, this hospital became a similar school of orthopedic surgery. There are some who have since become eminent orthopedic surgeons who honored me with their presence (a few are present now), who became my students and to whom I gave instruction. Without being invidious I may mention some of them—Ridlon, Gillette, Lovett, Myers, Packard, Fitzhugh, Young and Schapps; also the late Sidney Roberts and the late Samuel Ketch.

And there is another of my assistants and pupils, who shall be nameless, who yet deserves a passing notice.

I had been for nearly twenty-eight years an active officer of the New York Orthopedic Dispensary and Hospital, and for twenty-two years its surgeon-in-chief, when a crisis arose in hospital management involving the fundamental principles of control by the senior medical officer. I was then blessed and favored by an assistant who employed his peculiar talents in, at least, assisting in bringing about a condition of affairs which could only result in the sacrifice of this essential, indeed, vital principle, or the resignation of the surgeon-in-chief. The latter alternative was successfully accomplished.

Others of my younger associates and assistants who honored me with their confidence and were my pupils have drifted into general surgery since leaving the hospital, and being general surgeons have made orthopedic work a sort of kite-tail to their general work. All of these men, including those I have named, had a training which cannot be duplicated to-day, in the most important and essential part of orthopedic surgery, that is, the art and science of prescribing, applying and adjusting apparatus. It might be well if the future student of orthopedic surgery should spend at least a year in some properly equipped shop, just as the various colleges and universities demand of students in their engineering department a term of laboratory work in the course leading to the degree of C.E. The orthopedic surgeon should know more than his instrument maker. He should be able to devise the apparatus needed. He should be competent to direct its manufacture. He should know how to alter and adjust it to the conditions for which it was devised—in short, he should be able absolutely to control the situation. How many men practicing orthopedic surgery to-day fulfil these conditions? Not many!

And why? First of all comes the lack of facilities for proper preliminary education. Then again I am afraid that it is considered by some of our best-known men that mechanical work is *infra dig.* They are willing that the instrument maker should measure for, and after manufacturing it, adjust the apparatus to the patient. Another reason is that since the advent of aseptic surgery, operative measures have come to the front, and mechanical means have been relegated to the background. An important reason lies in the ever ready, often useful, but generally baneful, plaster-of-Paris bandage. I think it safe to say that 90 per cent. of the non-operative deformities of childhood can be more scientifically treated and more intelligently handled with properly constructed apparatus, than by the use of the gypsum bandage—and, I am sure, ultimately with much better results.

A cynic might say, in the present status of affairs—for an orthopedic surgeon must necessarily be an operative surgeon—that all that is needed to transform a general surgeon into an orthopedic surgeon is for the former to become an adept in the use of the plaster-of-Paris bandage. That this criticism can be made with some degree of justice, so far, at least, as the operative treatment of deformities is concerned, emphasizes the weak point of the present-day orthopedic surgery; that is, the lack among those practicing it of a thorough training in the thing which has been the most important formative influence in orthopedic surgery, which distinguishes it from general surgery, and which, if orthopedic surgery is to exist as a distinct branch in the future, must be cultivated and progressively developed—the intelligent and scientific use of apparatus. While this is all so—and this deficiency, which all must deplore, exists—nevertheless in the lines of the study, and investigation of the causes of the deforming diseases of childhood; in the way of devising operative and exceptionally mechanical measures for their relief; in the cause of the advancement of public philanthropic measures for the amelioration of this large and interesting class of sufferers, the orthopedic surgeon of America stands out prominently to-day in the scientific and humanitarian worlds.

Fraudulent Advertising by Physicians.—The secretary of the state board has received a lying advertisement from a paper from the southern part of the state, in which the advertising doctor promises, among other things, to cure appendicitis without the knife. Unfortunately this doctor is a licensed physician. The state board can do nothing with such cases unless it can be shown that the advertiser is guilty of "dishonorable conduct." While the promise to cure when one knows he cannot cure by the promised means is, in the physician's view, always dishonorable, this would scarcely be good evidence before a jury; and until such evidence can be secured the board can do nothing. The local prosecuting attorney should be consulted in all doubtful cases, and sometimes it is possible to convict on a charge of obtaining money under false pretenses. All quacks live on false advertising. Try moral and other suasion on the editors. Not all of them are pachyderms. Get the ads. out of the papers and the prosperity of the quack ceases.—Editorial *West Virginia Medical Journal.*

BACTERIAL INVASION OF BLOOD AND CEREBROSPINAL FLUID BY WAY OF LYMPH-NODES

FINDINGS IN LYMPH-NODES DRAINING THE PELVIS *

E. E. SOUTHARD, M.D.
Pathologist to the State Board of Insanity; Director of the Psychopathic Department of Boston State Hospital; Bullard Professor of Neuropathology, Harvard Medical School

AND

MYRTELLE M. CANAVAN, M.D.
Pathologist to the Boston State Hospital

BOSTON

The present communication is the fourth of a series dealing with a possible path of meningeal infection. The previous (or third) and second communications dealt with the bacterial invasion of the blood and cerebrospinal fluid in the light of findings, respectively, in the bronchial (fifty cases) and the retroperitoneal (thirty cases) lymph-nodes, and in the mesenteric (fifty cases) lymph-nodes. The second (or mesenteric lymph-nodes) communication developed an idea based on a previous paper by Gay and Southard[1] on the general significance of bacteria cultivated from the cadaver.

Our efforts have been directed at throwing light (so far as routine necropsy cultures might) on the curious fact observed by Gay and Southard that, whereas 41 per cent. of the bloods remained sterile with the methods used, on the other hand only 28 per cent. of the cerebrospinal fluids remained sterile.

Concerning the general problem we shall say no more than that the blood percentages obtained by Gay and Southard with insane hospital material compare well with those of other workers (mentioned in previous communications) with general hospital material, that our work has not necessarily anything to do with the general controversy between the "intravitalists" and the "postmortalists" as to the meaning of bacteria grown from the cadaver, and that there are no available data from other workers concerning our high positive percentages in the cerebrospinal fluid. The cerebrospinal fluid has been shown by Gay, and independently by McKenzie and Martin, normally to contain no bacteriolytic substances, whereas the blood is well known to contain such both in life and for some time after death.[1]

We were led to the obvious idea that bacteria from whatever source—infected lesion or some surface drained by lymph-nodes—might enter the blood, infect the meninges, die out in the blood, and persist in the cerebrospinal fluid. (Of course, it is also conceivable that organisms may in some way enter the cerebrospinal sheath from lymph-vessels without passing through the blood: the solution of the latter problem can hardly be by such statistical work as we now report.)

In point of fact, our cultivations from three loci (mesenteric lymph-node, blood and cerebrospinal fluid) gave the expected result that the most frequent positives in two out of three loci occurred precisely in the lymph-node-fluid combination. Fortunately for certain purposes, though unfortunately for others, our mesenteric lymph-node comparative cultivations were made during a dysentery epidemic, which so enriched the flora with secondary invaders that actually 55 per cent. of the cases gave positive results (with one or more organisms) from all three chosen loci[2] (mesenteric lymph-node, blood and cerebrospinal fluid).

We went on to study in similar comparative fashion the organisms cultivable from bronchial lymph-nodes, blood and cerebrospinal fluid.[3] The fluid persisted in leading both blood and lymph-nodes in percentages of positive cultivations. But, although the bronchial lymph-nodes led the blood in positives, yet the combination of positives in lymph-node and fluid was decidedly uncommon in this bronchial node investigation. Also only 35 per cent. of the cases yielded positives in all three loci (bronchial lymph-node, blood and cerebrospinal fluid). Accordingly we suspected that the bronchial lymph-nodes had somehow less to do with invasion of the cerebrospinal sheath than the mesenteric lymph-nodes.

We then resorted to cultivations from retroperitoneal lymph-nodes[3] against the other loci. In the latter small series (thirty cases) we actually found the lymph-nodes leading the cerebrospinal fluid as well as the blood in point of positives. Moreover, we found the retroperitoneal series resembling the mesenteric series in the preference among binary positive combinations displayed by the lymph-node-fluid combination.

The mesenteric lymph-node results, as hinted before, may have been essentially modified by the epidemic conditions in the summer of 1909 at the Danvers hospital. We felt that an investigation narrowed to lymph-nodes draining the pelvis would offer us special correlations with particular lesions and germ-bearing surfaces. Instead of general hospital conditions tending to swell and infect the mesenteric lymph-nodes, we should study special conditions tending to produce localized invasions.

Here perhaps it may be observed that we are taking sides rather with the intravitalist than with the postmortalist in respect to these invasions of various parts of the body by bacteria.

The results in our twenty-eight pelvic lymph-node cases are given in Table 1.

TABLE 1.—PELVIC LYMPH-NODE SERIES

		Percentages		
Hrs. post mortem	No of Cases	Heart's Blood	Cereb. Fl.	P. L.-N.
0—2	1	0	0	100

There are perhaps again no significant differences in the flora of these loci as cultivated post mortem. If the invasions are post mortem, the chances favor the hypothesis that the invasions occur early (say in the first few hours) after death.

The kinds of bacteria cultivated are shown in Table 3. As in former work, Chester's "Determinative Bacteriology," 1901, has been largely followed.

TABLE 3.—TWENTY-EIGHT NECROPSIED CASES

Growths from two regions and not from the third:

	Cases
Heart's blood and cerebrospinal fluid	3
Heart's blood and pelvic lymph-node	3
Cerebrospinal fluid and pelvic lymph-node	3
Growths from all three regions	10

It is interesting to note that these pelvic lymph-nodes, like the higher group of retroperitoneal lymph-nodes studied in the previous communication, are richer in positive cultivations than the cerebrospinal fluid. It is accordingly not unlikely that, as a general rule, the pelvic and retroperitoneal lymph-nodes are more likely to harbor micro-organisms than the mesenteric or the bronchial lymph-nodes.

Like the groups previously studied, the pelvic nodes persist in leading the heart's blood in percentage of positive cultures. This, we assume, is but natural not only because the lymph-nodes are nearer the usual sources of bacteria, but also because in the fluid blood organisms which reach it are readily killed.

No further example (like one in the retroperitoneal series, 1414) of a positive blood with other loci negative was found in the pelvic series.

Since all the binary combinations are equally productive of positive cultivations, no conclusion can be drawn as to preferences for the different loci.

Three cases yielded the same organism in all three loci:

CASE 1.—14679, Path. 1398, man aged 46, general paresis, with purulent prostatitis, showed *Bacterium anthracoides* in pure culture in pelvic (inguinal), mesenteric, bronchial lymph-nodes, in heart's blood and in cerebrospinal fluid.

CASE 2.—15255, Path. 1404, man aged 40, general paresis, with pulmonary tuberculosis, hypertrophied prostate and injected bladder, showed *Bacterium gallinarum* in bladder, pelvic lymph-node, blood and cerebrospinal fluid; *Bacillus formosus* in lymph-node along aorta; *Bacterium anthracoides* and unidentified cocci in pus from right ear, and unidentified cocci in other pelvic and in retroperitoneal lymph-nodes sixteen hours post mortem.

CASE 3.—14779, Path. 1413, male, aged 16, dementia praecox, with injection of prostate and bladder and death from typhoid fever and peritonitis, showed in urethra, pelvic, retroperitoneal and aortic lymph-nodes, heart, cerebrospinal fluid, *Bacterium sanguinarium*, in peritoneal fluid *Bacterium pallescens*, two hours post mortem.

The foregoing three and six other cases showed the same organism in pelvic lymph-nodes and in cerebrospinal fluid (nine cases).

CASE 4.—14656, 1385, woman aged 46, Huntington's chorea, *Bacterium anthracoides*, nine hours post mortem.

CASE 5.—15195, 1396, woman aged 51, organic dementia, cocci, sixteen hours post mortem (cocci also in decubitus).

CASE 6.—15495, 1397, woman aged 59, involution melancholia, *Bacterium anthracoides*, thirty-nine hours post mortem.

CASE 7.—15497, 1402, man aged 36, status epilepticus, *Micrococcus lactis*, twelve hours post mortem.

CASE 8.—12367, 1409, man aged 57, manic-depressive, *Bacterium truncatum*. eighteen hours post mortem.

CASE 9.—15577, 1416, woman aged 68, organic dementia, *Bacterium citreum*, nine hours post morten.

These findings raise the hypothesis of invasions (whether antemortem or postmortem is here of no account) of two loci often supposed to be closed from one another: a ready hypothesis might be that in the first three cases listed the blood served to spread the bacteria either mechanically or as a growth medium, and that in the last six, the blood, if ever invaded, had killed out its contained bacteria.

In connection with pelvic nodes, it becomes of interest to inquire whether or not acute or chronic pelvic lesions bear any relation to the bacteria cultivated from the nodes. As is not infrequent in insane hospital material, pelvic lesions were numerous. There were in fact but five cases, in which acute or chronic pelvic lesions can be safely excluded according to the necropsy protocols; these five cases yielded sterile pelvic lymph-nodes (1387, 1388, 1406, 1410, 1414), although other lymph-nodes and loci yielded various cultivations.

Of the twenty remaining cases, all but two had pelvic lesions of an acute appearance (four associated with chronic lesions); the remainder (1397 and 1415) have only chronic lesions. Only five of these twenty cases of pelvic lesion failed to show bacteria in pelvic lymph-nodes (1393, prostatic cysts, psoas abscess; 1395, acute cystitis; 1401, rectal injection (lesion?); 1407, acute cystitis (gastric carcinoma); and 1417, injection of bladder. As can be observed, at least three of these cases are to no marked degree diseased as to pelvis, if at all.

As to the general capacity of these loci to receive and care for the larger groups of bacteria (Chester following Migula), we find:

Cocci: in lymph-node 5, cerebrospinal fluid 7, heart's blood 8.

Bacilli: in lymph-node 14, cerebrospinal fluid 10, heart's blood 11.

Bacteria: in lymph-node 4, cerebrospinal fluid 0, heart's blood 3.

SUMMARY AND REMARKS

1. This continuation of our former work shows that the cerebrospinal fluid (72 per cent.) still leads the

heart's blood (68 *per cent.*) in percentage of positive cultures (routine aerobic methods, post-mortem material).

2. Pelvic lymph-nodes (like mesenteric nodes in our former work) lead both blood and cerebrospinal fluid (75 per cent.).

3. This is possibly due to the great percentage of pelvic lesions in the present series (twenty out of twenty-five cases; fifteen of the twenty showing organisms in pelvic lymph-nodes).

4. It is still uncertain whether these findings indicate ante-mortem or post-mortem invasions. Of course an acute or chronic lesion may conceivably help the penetration of organisms from without.

5. If (as seems likely) the invasions are intravital or agonal, then it would appear that the pelvic lymph-nodes are *accustomed to harboring many bacteria* (compare the mesenteric lymph-nodes in an epidemic of dysentery[2]).

6. Whether this habit of receiving more organisms than other nodes induces any superiority on the part of these nodes in respect to their power of digestion, we cannot say. If so, a rationale for Fowler's drainage position (upper part of abdomen maintained higher than lower part), might be imagined. Such a rationale would be superior to saying that the pelvic peritoneum is a better filter than others or is differently constructed from peritoneum elsewhere.

7. The pelvis, often subject to acute and chronic disease in the insane, appears to supply its lymph-nodes with very numerous bacteria (both motile and non-motile and of many groups). Some of these are saprophytes, some doubtless pathogens: they are often found in the cerebrospinal fluid post mortem, even when absent (destroyed?) in the blood. The pelvis compares, under the random conditions studied, with the intestinal tract in its habit of supplying bacteria to regionary lymph-nodes; and perhaps the pelvis surpasses the intestinal tract, since the latter's lymph-nodes happened to be studied during an epidemic of intestinal disease which provided an excess of secondary invaders.

8. The hypothesis of a route of meningeal invasion by way of the blood receives added support from this work, although the possibility of more direct invasion must be considered.

ABSTRACT OF DISCUSSION

Dr. H. E. Robertson, Minneapolis: For many years the bacteriology of dead bodies has been the subject of a great deal of discussion, and considerable contempt has been thrown on attempts to isolate pathologic micro-organisms from the body after death and draw any conclusion in regard to their influence on the body before death. There are still some questions which we should like to have Dr. Southard settle for us. Are all kinds of bacteria continually entering the blood from the intestinal tract and continually being taken care of by the protective influences of the blood? This question might perhaps apply not only to the blood, but also to the lymph and the cerebrospinal fluid. What is meant by the agonal invasions of bacteria into the blood and the lymph-nodes? Have we any particular reason to believe that there is any more invasion into the blood and lymph-nodes during abnormal processes than continually during the normal life? Have there been any actual experiments to show whether or not bacteria do pass out into the fluid of the peritoneum, *into the* blood-vessels or into the lymph-streams after death?

Dr. Henry Albert, Iowa City, Iowa: Were examinations of the blood and cerebrospinal fluid made before death in those cases in which they were made at *post-mortem*? In what proportion of the cases was the dysentery bacillus found in the mesenteric lymph-nodes?

Dr. E. E. Southard, Boston: I had thought from the early work that organisms were continually going through from the intestines into the blood and being continually killed there, and I was somewhat impressed with the work of McDonald concerning the probable infective condition of normal organs during life in most cases. When I found, however, how few cultivable organisms there were in my Boston series I began to wonder whether this was the case. Someone ought to endeavor to make a complete bacteriologic study of the dead body. I do not suppose that anyone has ever done that. Until that is done I do not see how the question of the continual supply of the blood with the bacteria can be settled, but I am of the opinion that it is a continual supply, perhaps from the lymph-nodes, but perhaps more often from the pelvis. Agonal invasions should be less common than non-agonal invasions on account of the well-known immobility of persons who are dead. Experimental work in this department should be done on various parts of the body. In fact, I have been tentatively doing some work in this direction in the pelvis, which I hope I may be able to bring evidence of at a future meeting. An elaborate report of a dysentery epidemic was published in the *Boston Medical and Surgical Journal* in 1910. A rather small number of dysentery bacilli were cultivated in that series. In a certain number of cases comparisons of the blood have been made, but the number is not large enough to warrant any statistical conclusions.

REPORT OF THE COMMITTEE ON THE TREATMENT OF PUERPERAL FEVER[*]

BARTON COOKE HIRST, M.D.
PHILADELPHIA
ROBERT L. DICKINSON, M.D.
BROOKLYN
JOSEPH B. DeLEE, M.D.
CHICAGO

At the last meeting of the American Medical Association held at Atlantic City, Dr. T. J. Watkins read a paper on the treatment of puerperal infection, advocating a non-interfering, expectant policy. In the discussion that followed, two widely divergent opinions were voiced. Some would immediately attack the uterus and empty it of its contents; others would wait for Nature to expel ovular remnants.

In proposing that a committee be appointed to investigate the subject, three purposes were kept in mind: (1) to obtain the opinions of authorities and of the profession at large, thus to learn what is the general teaching and practice of to-day; (2) to call general attention to the importance of the subject; (3) if possible, to formulate a course of procedure which would be generally applicable to the treatment of sepsis with retained ovular material.

It was decided to send a letter of inquiry to the profession. The questions reproduced herewith were sent out as follows: 400 letters to professors and assistant professors of obstetrics and gynecology in the United States and Canada; 200 to professors and assistant professors of surgery in the United States; 60 to professors of obstetrics and gynecology abroad—to England, Ireland, Scotland, Germany, France, the Netherlands, Russia and Italy. In addition, the first three questions were published in The Journal.

In all, 302 replies were received, of which 197 came from obstetricians and gynecologists, 53 from surgeons,

---

[*] Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

38 from foreign gynecologists and 14 from general practitioners who saw the questions in THE JOURNAL.

Following is a detailed classification of the replies. In advance it must be stated that although the questions were prepared with great care and made as direct as possible, so as to elicit an opinion that could be readily classified, still a certain amount of freedom was expected in answering, and we did not anticipate dogmatic unqualified statements. The results, on the whole, were good, since it was possible in nearly all instances to judge from the general tone of the answers what was the individual practice of the writer.

Question 1.—"A primipara with septic abortion at three months, fever two days, hemorrhage negligible, the ovum intact, retained. What would you do?"

This question was intended to cover that large class of cases in which the criminal abortionist has attempted to induce abortion in one way or the other and has succeeded only in infecting the uterus and its contents. by twelve of the writers this question was misunderstood, they holding that the ovum had been expelled intact. In later blanks issued, the word "retained" was added. It is probable that the words *in situ* would have been better, although only 4 per cent. did not grasp the exact meaning. We divided the replies into three groups: First, those who would clean out the uterus; second, those who would treat the uterus expectantly, only interfering when hemorrhage or other condition demanded: and third, those who would use mild disinfectant and expectant treatment, such as uterine douches and gauze packing.

TABLE 1—ANSWERS TO QUESTION 1

	Clean Out	Expectant	Mild Disinfectant and Expectant
189 Obstetricians and gynecologists ..	139	32	18
51 Surgeons	42	4	5
37 European authorities	32	0	5
14 General practitioners	11	0	3

Question 2.—"A primipara with septic abortion at three months, fever two days. hemorrhage negligible, the fetus expelled, placenta retained. What would you do?"

The same division of the replies was made.

TABLE 2.—ANSWERS TO QUESTION 2

	Clean Out	Expectant	Mild Disinfectant and Expectant
197 Obstetricians and gynecologists..	156	33	8
49 Surgeons	41	3	5
38 European authorities	33	2	3
13 General practitioners	10	0	3

Question 3.—"A primipara, fourth day after full-term delivery, positive evidence of uterine infection, no hemorrhage, retention of ovular remnants suspected. What would you do?"

This question was very carefully drawn, because it was the object of the committee to discover on how much, or how little, provocation the uterus was invaded after labor at term. Furthermore, in actual practice, it is very difficult to be certain that there are ovular remnants in the uterus.

TABLE 3.—ANSWERS TO QUESTION 3

	Clean Out	Expectant	Mild Disinfectant and Expectant
183 Obstetricians and gynecologists ..	136	34	13
52 Surgeons	36	4	12
38 European authorities	27	4	7
13 General practitioners	8	0	5

It will be noted that in general the treatment advocated for these three conditions is about the same by the individual operator; i. e., it is clean out or not in all three cases. The totals do not always tally because some men did not answer all the questions.

Question 4.—"If you (a) believe in active interference, (b) when do you do it?"

The committee wished further to know how urgent interference in septic cases was considered, and therefore propounded Question 4.

TABLE 4.—ANSWERS TO QUESTION 4

(A) ACTIVE INTERFERENCE

	At Once	Within 24 Hours	Later
154 Obstetricians and gynecologists..	128	8	18
41 Surgeons	32	0	9
33 European authorities	24	7	0
9 General practitioners	6	0	3

(B) TIME OF INTERFERENCE

	Obstetricians and Gynecologists.	Surgeons	European Authorities	General Practitioners
Curet—dull	70	21	9	6
Curet—sharp	19	5	0	0
Curet—not named	24	7	10	0
Finger	127	33	34	0
Placenta forceps	96	22	14	0
Tampon	39	18	11	0

Very few operators specified one or the other method as an exclusive one. Nearly all would use the finger as a method of preference, the others as aids, or where it was impossible to insert the finger. A few specified that the finger was more dangerous than the curet.

Question 5.—"What do you do when hemorrhage complicates sepsis?"

The idea of this question was to learn how many men became more active in the treatment when hemorrhage was added to the indications for interference.

TABLE 5.—ANSWERS TO QUESTION 5

	Tampon	Douche	Curet	Finger	Medicines
Obstetricians and gynecologists	92	20	72	42	31
Surgeons	29	6	16	16	5
European authorities .	15	4	7	8	3

From this maze of answers it was possible to elicit these facts: The majority of operators do not fear to pack a septic uterus. The majority believe in emptying the uterus fully to stop hemorrhage. Few use medicines as adjuvants and still fewer use them alone.

Question 6.—"If you believe in trusting to Nature when ovular remnants are retained, how long do you wait before operating?"

Those practitioners who trust Nature to throw off the retained material usually believe that it is more dangerous to interfere than to wait, and that active treatment of the uterus spreads the infection by breaking down Nature's barriers. We already learned what is done when hemorrhage complicates sepsis (Question 5)—we wished further to learn how long it was considered wise or safe to wait on Nature—how long a time was considered sufficient for Nature to put up an efficient barrier against the invading finger or curet. Unfortunately, these points could not be elicited from the answers.

TABLE 6.—ANSWERS TO QUESTION 6

	Wait 24 Hours	Wait 24 to 48 Hours	Wait Longer than 48 Hours
32 Obstetricians and gynecologists...	4	7	21
4 Surgeons	0	1	3
2 European authorities	0	1	1

It seems, of those who were willing to wait, the majority felt safe in waiting two days or longer. One author stated that he waits two or three weeks.

Question 7.—"Do you try to distinguish between sapremic and bacteriemic states before operating? How do you do it?"

Not long since it was believed that if a hemolytic streptococcus were found in the uterus, local interference was very dangerous, since it would almost surely be followed by a bacteriemia, but that if only saprophytic organisms were found in the uterus local interference was safe. We wished to learn how many still believed it is possible to discover whether the germs in the uterus possessed invasive qualities or not, or that they were able in any way to differentiate a purely local infection with absorption of toxins (generally known as sapremia) from a general infection (generally known as bacteriemia).

TABLE 7.—ANSWERS TO QUESTION 7

	Try to Distinguish	Do Not Try to Distinguish	Depend on Uterine Cultures	Depend on Vaginal Cultures	Depend on Blood Cultures	Depend on Clinical Symptoms	Depend on Exploration
Obstetricians and gynecologists	80	79	40	21	28	42	3
Surgeons	16	27	11	0	4	11	0
European authorities	12	22	7	1	4	9	0

Only half of the writers believe a distinction practical. It must be admitted that European accoucheurs, in general, have better facilities for such differentiation than we do, yet with them twenty-two of thirty-four believe it is impractical.

Question 8.—"Do you make any distinction between the treatment of sepsis after abortion and that after full-term delivery?"

We might have gathered this information from a careful study of the answers to Questions 1, 2 and 3, but it was thought best to get the direct replies.

TABLE 8.—ANSWERS TO QUESTION 8

	Make Distinction	Do Not Make Any	More Active in Abortion	Less Active
Obstetricians and gynecologists	57	90	53	4
Surgeons	14	23	14	1
European authorities	9	22	9	0

The replies of those who made distinctions in the treatment of the two instances of sepsis are significant, the vast majority, fifty-three of fifty-seven, are for more active treatment in abortions. Some writers specified criminal abortion as an indication for immediate emptying and exploration of the uterus. Many would use the finger for full-term uteri, the curet for early abortions. Some would pack or douche the full-term uterus and use the curet in early pregnancy. One man wrote that he never invaded the uterus in sepsis after full term, but that he regretted it.

In the general remarks, twenty authors specifically stated that their practice is more expectant than formerly; one that he is more active locally than he used to be. Four state that active treatment sometimes kills the patient and two are frankly undecided as to the best course to pursue, and one acknowledges that he feels helpless in these cases. Twenty-four writers are inconsistent in their general remarks as compared with their replies to the questions, which may have been due to possible ambiguity of the latter. One writer believed that cultures from the urine would enable a diagnosis to be made of the nature of the infection.

It was not expected by the committee that definite and dogmatic answers would be returned to each question, but in this we were agreeably disappointed. It was possible in nearly all cases to determine the actual practice of the writer as to the matter at issue. What was impossible, however, was the proper evaluation of the opinions expressed. As may be seen, the replies came from obstetricians and gynecologists and surgeons holding teaching and hospital positions, from European authorities, and a very few from general practitioners. It may safely be said that the opinions are the best obtainable, yet opinions are of two kinds, resembling in this respect coins and bills. Coins have an intrinsic and a face value, bills only a face value, so also are opinions; and the ones we received are not exceptional, but it would have been a work of supererogation for us to try to separate and classify them. Two writers frankly told us that the opinions of the majority were of no value, but that light must come from the men at the top. In forming our conclusions, due weight was given to this point.

CONCLUSIONS

The majority of accoucheurs and surgeons clean out the septic uterus at once, but a not negligible minority believe that it is safe to trust the expulsion of the infected uterine contents to the powers of Nature, some assisting the same by mild measures such as antiseptic douches and packing. From this it is fair to infer that, in the majority of cases, it has been found safe to invade the infected uterus with finger and curet, and this is borne out by experience. There are, however, many cases in which the infection is of such a nature, or the resistance of the patient of so poor a quality, that the sudden introduction into the system of so large an amount of bacteria and toxins, as is always made by curettage, turns the scale against the patient. She cannot stand the inoculation with autogenous vaccines. The experience of the minority has proved that ovular remnants, even though infected in the uterus, do not create such dangerous conditions as we formerly believed, demanding instant removal, but that it is safe to wait for Nature to erect her own barriers against the progress of the infection, and that temporizing measures, or mildly stimulating ones, often suffice for cure. We all feel the need of some method by which it would be possible to distinguish benign from virulent bacteria living in the genitalia, but as yet no such method exists. When it does become possible, our practice will become more definite. At present one-half of the authorities do not try to make the distinction, holding it impractical. One point that was almost invariably emphasized was that after the uterus was once emptied it should not again be invaded by either finger or curet. Few would permit antiseptic douches. This is a very grateful change from the time when repeated curettages were performed on the puerperal uterus—a procedure which was as rational as curetting the throat in diphtheria. Another interesting fact that was developed is that quite generally the tampon is used to stop the bleeding in infected cases. Evidently there is not much fear of damming back the infection and permitting greater absorption.

ABSTRACT OF DISCUSSION

Dr. E. E. Montgomery, Philadelphia: The profession is indebted to Dr. DeLee for calling attention to the importance of this subject, on which there is the greatest variety of opinions. I must confess that, since my attention was called to it. I have varied somewhat from the statement I made of my own conduct in the treatment of these conditions. It had been my custom in these cases, when I could recognize material undergoing decomposition within the uterus, to remove it. I prefer the gauze-wrapped finger to the curet, as the decomposing material can be as thoroughly removed and with less danger. The cavity is painted with the tincture of iodin and packed with iodoform gauze. The gauze affords advantage in separating the surfaces, favoring the formation of establishing a wall which closes the vessels and thus permits us to remove the putrid material. If the uterus is infected and the ovum still intact I have felt it wise to evacuate the uterine contents. I have had cases in my service at the Jefferson Hospital in which we have waited, and in one of them, when the abdomen was opened later, the entire uterus was covered with an exudate and the pelvis filled with dirty material which necessitated, in our judgment, removal of the uterus in order to give the patient a chance for recovery.

My experience with patients in the hospital—and we see many who have been treated by midwives and subsequently seen by our men of experience—is that it is almost an invariable rule to curet them, sometimes even a second time. This is because they are of a class which, if not relieved by immediate operation, are rushed off to another man, who feels that he must appear to be doing something and again curets. Invariably, I try to bring these patients into the hospital because there they are under control. Although a number have come in with a temperature of from 104 to 106 degrees it has been my rule not to subject them to any further operative treatment. I remember a recent case in which the patient entered with a temperature of 106 after a second curetting. I made no attempt to investigate the uterine cavity. By keeping the patient quiet and under palliative treatment the temperature was normal within a few days and she was able, at the end of ten days, to leave the hospital.

In my experience, although the patient may be suffering from active septic infection, it is unusual to find the streptococcus in the blood. Most frequently we find the blood-culture negative. This is particularly true when the infection involves the vessels, causing thrombus and phlebitis. While it is evident that the patient is suffering from infection the blood-culture is negative. This has been shown by some writers to be due to the fact that streptococcus lodges on the sides of the vein and is not carried into the blood-current.

Dr. J. C. Litzenberg, Minneapolis: I have as a guest at my home a country practitioner, and to that class of physician I give great honor. He said to me last night, "Why did Dr. Murphy emphasize so much his condemnation of the curet? Does anyone use the curet now?" That is pretty good, coming from the country practitioner. Speaking not of the puerperal uterus, full term, but of abortions, I think that every incomplete abortion should be completed by the obstetrician at once, but I am greatly impressed with the ideas of those who advocate the extreme conservative position. I make a distinction between the uterus at full term and the uterus in abortion. It has been my practice always to empty the uterus in abortion, but not immediately in septic abortion. I use gauze and wait. If the uterus is dilated enough so that the placental forceps can grasp any portion of the retained ovum I use the forceps, but not the finger or the curet. If there is no hemorrhage I do not pack; if there is, I do.

I am becoming more and more conservative in the treatment of these cases and I find that the more chance Nature has the more she will do for us.

Dr. Robert T. Frank, New York: The country practitioner may not use the curet, but I am quite sure, from what I have seen in New York, that the city practitioner uses it, and much too often. I have seen cases of what we generally term puerperal sepsis—the term to which Dr. Murphy objected and for which he wants to substitute a more definite pathologic term. I have seen three or four men of high standing in consultation over such a case and each of them interpret the condition in quite a different way. Therefore, it seems to me, just as Dr. Murphy and Dr. DeLee suggested, that so long as we cannot view the organs outside of the body, we should look for a method by which, even if we do make a mistake in interpreting the exact pathologic state, we shall do the least harm; and that, after all, is usually by the expectant treatment.

In abortions I believe that infection is often due to the hasty examination made by the general practitioner when the patient is bleeding and he fears that she will bleed too much. In the puerperal cases the greatest difficulty lies in our inability to rely on the statements of the attendant as to whether the entire placenta has been expelled. If we are sure that the placenta is outside of the uterus after labor, the further question of emptying the organ cannot arise.

Dr. R. S. Yarros, Chicago: Not so very long ago every physician considered it his duty to empty at once the puerperal uterus if there was any suspicion of septic contents. That there were too many uteri curetted and that some of the results were bad, not only because of the use of the curet but because it was used carelessly and by inexperienced physicians, we all admit. It seems to me, however, that the present extreme fear of the curet in such cases is not justifiable since obstetricians in these days are being better trained in surgical work. Most cases in which we are called on to remove the product of conception are either clean, incomplete abortions or cases of sapremic infection, and in my experience I have for many years, after dilating the uterus thoroughly, emptied it with a medium-sized curet, irrigated with iodin solution and lightly packed with gauze with good results. It is a different thing in criminal abortion cases, in which there is more likely to be a streptococcus infection and in which the infection has probably gone beyond the uterus. Dr. DeLee and many of his followers believe that a slow emptying of the uterus, which is accomplished by packing, is the only right way of reaching such cases because of the good results that they have obtained, but I maintain that, in the proper hands, our method has just as good results and, in addition, the patient and the family are not kept in suspense about the outcome.

Dr. J. B. DeLee, Chicago: Dr. Yarros seems to have taken the defensive most sharply of all those who have discussed the report, and therefore I may perhaps be permitted to reply to that particular onslaught. I will quote the experience of my associate and collaborator, Dr. Stowe of Chicago, whose experience was gained in the same institution with which Dr. Yarros is connected. Dr. Stowe had been taught that every septic case should be curetted and he carried out this idea when he came into the hospital. He noticed that all the patients died. So he left them alone and they all recovered.

In conclusion, I shall answer the questions in the circular myself. 1. In septic abortions I try to determine, from the history and symptoms, if there is any perforating injury of the uterus. In this case, the abdomen is opened at once; otherwise the uterus is lightly packed with iodized gauze. Next day the gauze is removed and, unless the cervix is fully dilated, the uterus is again packed for twenty-four hours. The uterus is then emptied by means of the ovum forceps and the finger. 2. The treatment is the same as No. 1. 3. After full term or near term labor the uterus is not invaded unless there is hemorrhage. The patient's shoulders are raised to favor drainage and hygienic treatment and good nursing are provided. 4. I do not believe in active interference at once. When I do empty the uterus, I remove large loose masses by means of the ovum forceps, locate small adherent pieces and separate them with the finger, and only exceptionally use the curet. 5. When hemorrhage complicates sepsis, I tampon the uterus, and repeat this again, or twice, if necessary. 6. In case the presence of ovular remnants is only suspected, I do not interfere. 7. I always try to distinguish between sapremic and septicemic states before operating, but have never felt sure in operating that I was not starting a fatal illness. 8. I make distinctions in the treatment of sepsis after abortion and that after full term or near term delivery. In septic abortions I feel much safer in invading the uterus with finger and ovum forceps, and in a few cases I use the curet—never after labor. I am growing more and more conservative in the treatment of sepsis, and am delaying the time of interference as much as possible, to give Nature time to erect a good barrier.

SOME NEW MINNESOTA LAWS ON TUBERCULOSIS *

P. M. HALL, M.D.
MINNEAPOLIS

The discovery of the tubercle bacillus has changed all of our definitions of the disease. The discovery of a specific cure may change many of our methods of control, or our attempts at control. Ultimate control is the aim of all new methods or measures. The last fight against the disease will be made by the public health workers of the world. Changes have occurred both in treatment and in administrative methods; but always there has been progress. The question of control, of prevention rather than cure, naturally appeals to the public health worker. Minnesota has had some legislation on tuberculosis. It has been defined as a contagious and infectious disease and made reportable. A state sanatorium was erected about five years ago. The legislature authorized the appointment of a state advisory commission for this institution. These are some of the things which have been done looking toward control. Two years ago the legislature passed a bill authorizing counties to issue bonds for the purpose of erecting tuberculosis sanatoriums. This, it was thought, would stimulate interest which would result in the erection of sanatoriums in various parts of the state. It failed of its purpose. At the last session, therefore, the legislature passed another county sanatorium bill with the entirely new feature of state aid added. The bill also carried with it an appropriation of $500,000 to make the measure effective.

Some of the features of the bill may be of general interest. It provides that any county or group of counties, through their boards of county commissioners, shall have the power, with the advice and approval of the advisory commission of the Minnesota Sanatorium for Consumptives, to establish and maintain sanatoriums for the treatment and care of persons affected with tuberculosis. These sanatoriums may be established by a majority vote of the commissioners of any one county or group of counties, whenever the cost of construction to be paid by the county or group of counties shall not exceed such a sum as may be raised by a tax levy of not to exceed one mill on the dollar of the taxable property of any such county or group of counties. Whenever the cost of construction shall exceed the amount that might be raised by a one-mill tax, then the two questions of (1) whether or not such sanatorium shall be established and (2) whether or not such bonds shall be issued to defray any county's portion of the cost thereof shall be submitted to the voters of such county, and the sanatorium shall not be established unless a majority of the voters of such county shall vote in favor of each of the two propositions submitted to them.

If the county commissioners of any county shall refuse to construct such a sanatorium, then, on a petition of not less than 5 per cent. of the freeholders of such county, such question shall be submitted to the voters, and if a majority of the voters of such county, voting thereon, shall vote in favor of constructing such a sanatorium, then such a sanatorium shall be erected. On the decision to establish and maintain a tuberculosis sanatorium, the county commissioners shall appoint a commission consisting of three members, at least one of whom shall be a licensed physician, and whose appointment, before becoming effective, shall be approved by the State Board of Health. Such county sanatorium commission shall have full charge and control of all moneys received for the credit of the tuberculosis sanatorium and have full charge and control of the location, establishing, and maintenance of any sanatorium. But no site shall be secured and buildings erected or equipped without the approval and consent of the Advisory Commission of the Minnesota Sanatorium for Consumptives. Before final action is taken the plans and specifications shall be submitted to the State Board of Health for approval.

The State Board of Control shall have full power and control over the construction and equipment of any such sanatorium. A county or group of counties desiring to erect a sanatorium shall through their boards of county commissioners appropriate one half the necessary funds and deposit the same with the state treasurer. The bill further provides that the amount contributed by the state shall not exceed $50,000 to any one county, and that no sanatorium shall be constructed of smaller capacity than twenty beds.

After their construction these sanatoriums shall be under the charge and control of the county sanatorium commission. Preference is to be given to the patient with an advanced case and to the resident of the local county, but no person is to be turned away for lack of means if there is an available bed for his care. In case there are no relatives who should be responsible for the care of the patient, the state will pay to the county treasurer of the particular county the sum of five dollars per week. In counties in which a contract has already been let, or in which a sanatorium has already been built, the state shall refund to the particular county a sum equal to five hundred dollars for each available bed. To carry out the provisions of the bill an appropriation of $500,000 was made.

Besides this county sanatorium bill the legislature passed a bill for the better control of tuberculosis. It requires the reporting of all cases of the disease by physicians. This is provided for in a former law. The law further says that it shall be unlawful for the authorities in charge of any penal or charitable institution to care for any person afflicted with tuberculosis in the same room or ward with other inmates. Another section provides that the health officer may report to the board of county commissioners any person afflicted with tuberculosis whom he considers a menace to his family or the public, and, on the approval of the board of county commissioners, the health officer shall have the power to remove such person and place him in a public hospital or sanatorium in which he shall remain until discharged by the superintendent of such institution. This is another way to protect the public by compulsion in case protection by education has failed. This wise law would be without effect unless some place were provided where the vicious consumptive could be restrained. This is met, however, in the provision by the state for county sanatoriums.

Another provision of this bill is that no teacher, pupil, or employee about a school building who is afflicted with tuberculosis shall remain in or about such building, without a certificate from the board of health, or an agent duly authorized by the board of health, that such person is in no sense a source of danger to others. It is a poor rule that does not work both ways, so teacher and pupil are treated alike under this act. It provides for the proper disinfection of the premises following death or removal and for placarding the premises with a warning notice to the public until this has been done. This is thought to be the first bill providing state aid in the construction of county sanatoriums. How well it is to work

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis June, 1913.

out remains to be seen. The provision against the vicious consumptive is different than other laws in that it at least provides a place where the vicious individual may be restrained.

Pillsbury Building.

ABSTRACT OF DISCUSSION

Dr. S. A. Knopf, New York: I wish to take exception to a few points in Dr. Hall's paper. First of all, is tuberculosis a contagious or a communicable disease? In the law he cited it is called a contagious disease. Contagion comes from the Latin *contingere*, to touch. Is the mere touch of a tuberculous individual sufficient to transmit the disease? In New York we make a distinction between a contagious and a communicable disease, and I really believe that it is most unwise to classify tuberculosis with leprosy or small-pox, which are really contagious diseases. By calling tuberculosis contagious, we increase phthisiophobia, which is a disease in itself and productive of much harm and misery to the antituberculosis worker as well as to the patient. I hope that the law will be revised and that the word "contagious" will be replaced by the word "communicable." I hope that Dr. Hall will make a little more clear what he really means to do with the vicious consumptive. At the Riverside Hospital-Sanatorium, in which I am senior attending physician and into which we receive patients from all classes of society, some of them forced in, we occasionally find it difficult to restrain the refractory patient who does not wish to stay. The hospital is situated on an island and escapes are rare, but sometimes a patient will attempt to swim across. I should be most grateful to Dr. Hall if he would tell me what they do with the consumptive patient who voluntarily expectorates on the floor and who behaves badly in other ways, such as fighting with his fellow patients, using abusive language, etc. It was stated that disinfection should take place every time a patient dies. I should like to ask the speaker whether it would not also be a wise thing to inquire, once in a while, where and how the patient lives. I believe that we are neglecting that feature of prevention. It is well and good to disinfect after the patient has died; but sometimes consumptive patients live a long while and in the meantime have a chance to infect many apartments; hence, I believe that the disinfection of the domicile should be periodical and not only after removal at death. In the antituberculosis campaign we must always bear in mind that we are not to combat the tuberculous, but tuberculosis, which is a disease of the masses, and to combat it successfully we must have the combined action of a wise government, well-trained physicians and intelligent people—that is to say, the citizens at large.

Dr. V. C. Vaughan, Jr., Detroit.: There are three distinct types of tuberculous individuals with which we have to deal. The first is the advanced consumptive, who is a source of contagion to others, but is necessarily confined to bed; consequently, the area which is infected at any time is limited in extent. Persons of this class should, of course, be cared for in hospitals for the tuberculous. These hospitals should be state institutions located at some remote part of the state or the community in which the individual lives. Patients with advanced cases are glad to go to hospitals, provided that these hospitals are easy of access to their friends and relatives. This is a very important point, which evidently has been taken into consideration in connection with this law. The second type of case causes the greatest trouble — the moderately advanced tuberculous person who goes from place to place giving the infectious material and who continues to be a source of infection over a long period of years. These patients, of course, require sanatorium treatment; but it is impossible to build hospitals of sufficient extent to provide for them during the remainder of their lives. The hospital should be used as a training school for these patients. They should be taught there how to prevent the spread of infection to others and how to take care of themselves in institutions of this sort, and then they should be returned to their homes, and the public health authorities should demand that they follow the instructions which they have received. The third class, which we are finding more and more frequently, is made up of patients with incipient or early tuberculosis. These persons are not infectious; they never cough; they never will cough; and yet when the public-school teacher goes out from a sanatorium for tuberculosis to resume her vocation, she cannot find a position because she has been an inmate of a tuberculosis institution. This is a practical point and one arising constantly. In Detroit, I have even allowed such persons to refrain from reporting that they have been in institutions for the care of the tuberculous. The physician who will not allow anyone who has ever received treatment in an institution for tuberculosis to enter a family and perform certain household duties is partly to blame for this. That is going too far and is one of the things that keeps us from reporting all our cases.

Dr. Walter J. Marcley, Minneapolis: As a member of the State Tuberculosis Commission appointed by the Governor for the purpose of studying conditions and recommending legislation, I had something to do with the framing of these laws. In planning for institutions for the tuberculous we had in mind the need of popularizing the sanatorium treatment of the disease. We must remove what Dr. Knopf and others call "phthisiophobia" and teach the people that having tuberculosis is not so awful. We have felt that the clause in the law referred to providing for compulsory removal from the home should be administered very cautiously, but that its enforcement will be required in some rare instances. In Minnesota we wish to make these institutions, near the homes of the sick, attractive in every way so that patients will desire to go and remain as long as necessary. Furthermore, these sanatoriums will no doubt be — and they must be, if they are to meet the purposes for which they are intended — educational institutions in the communities in which they are established.

Dr. J. N. Hurty, Indianapolis: It is well to view every question from every angle. A soldier, who was addicted to morphin and whisky, came to me and wanted relief. He told me that he had little care for his old age; that he could dissipate and plunge into all manner of excesses because the country would take care of him at the Soldiers' Home. I find that the miners prefer to have small-pox, if they can have only a mild attack, in order to have two weeks' vacation at the expense of the state. They like quarantine and court it. Are we not liable sometimes to take too much care of the afflicted and of the unfit? Are we not putting a premium on the very conditions we are combating? To what will this lead? Insanity is increasing in my state, in which we have five great institutions, costing a million dollars. It costs $2,000,000 annually to take care of our insane and other defectives. We must now build a sixth insane hospital. Are we to keep on building institutions and doing nothing to prevent disease?

In Indiana during the last decade we have prolonged the duration of life of the insane eight years through the practical application of hygiene. Thus by our kindness and mercy and charity we have put forty thousand years more of burden on the shoulders of the citizens of Indiana. It seems to me sometimes that we are only increasing charity conditions. There is much talk about an old-age pension. If we give these pensions indiscriminately, just because a person has reached the age of 65 or 70 years, I believe that we will be in danger of increasing dependency and immorality; but if we give an old-age pension to those who arrive at a certain age in a certain stage of health, without syphilis, and immorally acquired diseases, we will be taking a step in the direction of prevention.

Dr. Otto P. Geier, Cincinnati: If quarantine against small-pox is worth while, quarantine and forcible detention against tuberculosis is certainly worth while, for it is a much more dangerous disease. Cincinnati has, I believe, as broad a program of prevention as any city. We have there the second highest death-rate from tuberculosis of any city in the country. Over a thousand people die every year in Cincinnati of tuberculosis. The Anti-Tuberculosis League has conducted an active campaign expending about twenty-five thousand dollars a year. We are building new additions to the Tuberculosis Hospital. We now have bed capacity for three hundred. We are building shacks and a detention ward. I want to emphasize the value of a detention ward. The superintendent of the hospital stated in his 1912 report that the forty thousand dollars expended last year on the tuberculosis problem was largely wasted because the average stay of the greater percentage of the patients was less than forty days. This percentage was made up of the riffraff of the town, the unemployed and unemployable, who were serious sources of infection when they went back to saloons and cheap tenement houses.

Dr. C. Hampson Jones, Baltimore: A similar law was framed in Maryland two years ago, but our legislature did not see fit to pass it. It differed from the present law only in the point that we have a central government in the board — a commission appointed by the governor several years ago — in charge of all the hospitals. I think that it will be thought best always to have one doctor on the several boards managing hospitals. Forcible detention is oftentimes really a great necessity, but, as a rule, the number who go voluntarily to the hospital is so great that we need not bother about the others.

I think that one phase of our work is really wrong. The so-called incipient case is cared for by the state or by the local communities. While I should not like to prevent any early case of tuberculosis being cared for by the city and the state, yet I think that, inasmuch as the state and cities are working for the protection of the public, they ought to do that which is the greatest protection for the public, namely, segregate the tuberculous.

Dr. L. S. B. Robinson, St. Paul: Dr. Knopf has asked the question, "How can we control unruly patients?" One method is illustrated by a case recently reported to me by one of our nurses. The patient was a man with a large family of children; he was careless regarding sputum, ugly and uncontrollable. He was permitted to become drunk and then arrested on a charge of disorderly conduct and committed by the judge for sixty days to the hospital, instead of to the workhouse. When he gets out he will be rearrested and recommitted unless he gives promise of behaving himself.

Dr. S. A. Knopf, New York: I believe that Dr. Jones is mistaken about the danger of the advanced case and the non-danger of the early case The patient with the advanced case may, I grant, produce more tubercle bacilli, but he is usually confined to four walls or his apartment, while the patient with the early or moderately advanced case is the typical bacilli carrier and distributer. He expectorates countless bacilli, and, if he is careless, he is a much more dangerous person than the patient confined to his bed or room. Both classes of patients should be taken care of and rigorous precaution concerning their sputum should be insisted on. To allow patients to become drunk in order to control them might be a pleasing pastime, but it would be rather expensive to the community; New York would, I am sure, not wish to have the hospitals spend money that way. To be serious, let us rather try another method and make the hospitals for the advanced cases so attractive and treat the patients so well that they will be only too glad to remain within them. Let us make the institution for the advanced cases not a place of despair but a place of hope. To this end I would plead that all so-called hospitals for consumptives be called hospital-sanatoriums as I designated the institution on North Brother Island. It is called the Riverside Hospital-Sanatorium. Many patients have the idea that to go to a sanatorium means to get well — to go to the hospital means to die. The hospital-sanatorium should be built near the city so that the patients' friends can see them frequently. Let us treat the advanced cases with the utmost kindness and consideration; make them feel that the hospital-sanatorium is a true home, in which it is even pleasant to die, if they have to die, and there will be no difficulty in filling our hospital-sanatoriums for advanced cases.

Dr. Liston H. Montgomery, Chicago: In certain instances of pulmonary tuberculosis a hereditary condition prevails, I believe, as well as a contagious or infectious element. Why use the word communicable? I think that this term is less understood by the laity, and given less value, than the term contagious; hence less reliance or less care will be used in taking precautionary measures to prevent the spread of the disease to others, than would be used if they were taught that the disease is contagious and infectious. Why do we disinfect and fumigate the premises of a patient who has died of tuberculosis, if contagion or infection is not present? Although I refer to tuberculosis as being hereditary in certain cases, I know that this is not the popular scientific view nowadays; but how are we going to get around the fact that a mother in an advanced stage of pulmonary tuberculosis gives birth to a child that lives perhaps a few weeks and is found at necropsy to have a well-marked tuberculosis? Call it predisposition in the child or susceptibility if you will, but to me it appears to be an undeniable fact that the disease was directly transmitted to the child from the mother; hence I have never been convinced that the disease is not hereditary. I do not wish, however, to be understood to say that it is always hereditary. Be this as it may, how is it that within the last few years we are drifting toward the science of eugenics?

Dr. Guy L. Kiefer, Detroit: At first, when I talked to lay audiences about these diseases, I believed in calling them all communicable. Now I believe in calling them all contagious; as we go along in the belief that all of the diseases are spread by contact directly or indirectly (and you can make the term indirectly just as broad as you wish to), I believe that it is better to have one term. We ought not to try to mystify the people whom we are trying to educate by using different descriptive adjectives for the different diseases, so long as the result we are trying to attain is to some extent dependent on the adjective we use. In New York, Dr. Knopf says the adjective in the law is communicable; in Michigan, the adjective used in the law is infectious, and in Minnesota it is contagious. If we use the word contagious, the very fact that the disease is described as contagious teaches the people some of the things that we are preaching, that they must not come and stay in close contact with a tuberculous patient, that they must not sleep together, in short, that they must not do the things that will spread the disease, bring the disease to them, by contact. It seems to me contagious is a good word, and that it would be well to let it stand.

Dr. S. A. Knopf, New York: If we should not make any distinction, if everybody should be taught that tuberculosis is contagious and that they should avoid coming in contact with tuberculous patients, where are we going to draw the line? Where are we going to get nurses and the help needed in sanatoriums and hospitals? We may even have difficulty in getting doctors. To be liable to contract tuberculosis one must be strongly predisposed, on the one hand, and, on the other, constantly exposed to the inhalation or ingestion of the tubercle bacilli. There is enough phthisiophobia rampant now, and we would better teach that tuberculosis is not a highly contagious but only a communicable disease and that the honest consumptive is not a danger to his fellow men.

Dr. J. W. Trask, Washington, D. C.: I do not think that the statement that the fear acquired by many persons of contracting tuberculosis would make it difficult to get nurses or to otherwise care for the sick or convalescent is entirely in accordance with the facts. Little, if any, difficulty is found in securing nurses for other infectious diseases, even for the most dangerous contagious ones. For many years those interested in the campaign against tuberculosis have endeavored to create in the minds of the people a wholesome fear of and respect for the disease, believing that it was only through the development of this fear and respect that people could be brought to properly protect themselves from infection; that only by this means could proper precautions be secured in the average home; that fear of the disease was necessary to keep the sick from sleeping with the well, to cause a proper disposition of the sputum and also proper cleanliness of dishes used by the sick. This fear of tuberculosis is a thing that has intentionally been fostered for sometime and has undoubtedly been of great assistance. I believe it to be a necessity in the successful fight which civilized nations are waging against the disease. If this fear at times creates hardship it is unfortunate, but must be expected. If the household in employing servants rejects all applicants who appear to have tuberculosis, an occasional injury may be done. If those working together in an office glance suspiciously at a coworker who has become emaciated and afflicted with a chronic cough, a hardship may occasionally be inflicted. In developing this necessary fear of the disease it is impossible that each person shall acquire just the right kind of fear and shall know just when to fear and when not to fear. To be effective the fear will usually need to be greater than that actually merited by the characteristics of the disease and its tendency to infect persons. The control of the disease will probably be much more readily accomplished with too great fear in the minds of the people than with too little fear.

DR. P. M. HALL, Minneapolis: We used the three words—contagious, infectious and communicable — in the same bill; thus we did away with the finer distinctions as to these various terms. I used the word contagious as a matter of convenience. My own belief regarding the vicious consumptive is that sanatoriums should be made so attractive that the patient will come voluntarily. Still, I believe that we should have the power to remove the vicious consumptive. We provide in the law for disinfection following death, and removal of the living patient from one place to another. If the patient dies in the place where he was taken sick, we disinfect that place. The large cities of the country to-day are taking care of the bulk of contagious diseases. The idea is to bring the sanatorium to the consumptive in order that he may be near his home. The question of state aid was suggested by the fact that many of the counties in the state are poor, and that the state could wisely spend money to combat this disease. We must get away from the idea that we are going to get rid of consumption on a cheap basis. It may cost a little more money to conduct a sanatorium of a hundred beds, proportionally, than one of 250 beds; something will have been gained in the way of education if the sanatorium is established in a county near at hand, where the people will learn from the institution that it is their duty to care for an infectious disease in their own immediate neighborhood. The consensus of opinion at present is that the death-rate from tuberculosis is decreased in proportion to the increase in number of beds. There is probably no city in the world that has done more effective work and with more definite, positive results, than the city of New York; and New York to-day has a proportionately larger available bed supply than any other city. In the state of Minnesota at present there are less than four hundred beds; and yet we have an annual death-rate of almost three thousand. Think of trying to meet these conditions with less than four hundred beds.

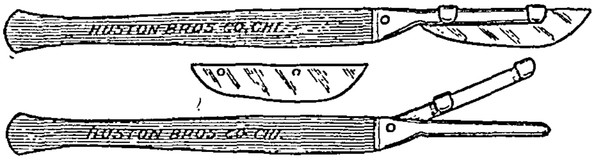
An advisory commission has definite supervisory control of all of these county sanatoriums. The idea was to place the management in a commission near at home; but the advisory commission has supervision of the county commission. Provision for the pay for free patients by the state is insured by the regulation that the state pay five dollars per week, in case the advisory commission certifies that the institution is properly operated and conducted.

An Inexpensive Efficient Sputum-Cup.—An inexpensive sputum-cup, to be used in an ordinary holder, may be made of ordinary white fiber manila paper, folded and dipped in hot paraffin, which, hardening immediately on exposure to the air, glues the overlapping edges and gives support to the box. Water heated to 100 F. will not penetrate a box made in this manner. Water at ordinary temperature will remain in them until it evaporates. Sputum-boxes may be made in this manner at a cost of 8 cents per hundred. The advantages of such sputum-boxes are: 1. They are inexpensive. 2. They afford employment for convalescing patients who make them. 3. Since they are white, the faintest tinge of blood is readily observed. 4. Paraffin being highly combustible, the destruction of any bacteria present is assured, when the used cups are burned.—ROBERT M. ALEXANDER, M.D., First Assistant Physician, State Asylum for Chronic Insane, Wernersville, Pa.

DETACHABLE SCALPEL BLADE *

J. A. MATLACK, M.D., LONGMONT, COLO.

In attempting to use safety-razor blades in surgical work I have found that a stock razor blade with a straight cutting edge is not practical. Such a blade if held in the usual position will have only the distal corner in contact with the flesh and will tear rather than cut, especially if used in the deeper parts of a wound. If the detachable razor blade is to be adapted to the surgeon's scalpel the blades as ordinarily made cannot be used with entire success, but must be specially ground with a rounded extremity or "belly" as in the usual type of scalpel. The accompanying illustration shows the instrument as I have modified it to meet this requirement.



FRACTURE OF ANTERIOR SUPERIOR SPINE OF ILIUM FROM INDIRECT VIOLENCE

CHARLES AUER, M.D., BRONX, N. Y.
House Surgeon, Lincoln Hospital

The infrequency of this injury from indirect violence and the ease with which it may be overlooked, warrant a report of its occurrence.

On June 20, the patient, J. J., aged 23, took three steps forward, kicked violently at a football and missed it. He did not fall from the force of the kick, but immediately felt weak on his right side when he attempted to walk. After some manipulation of the leg by friends, he was able, by limping, to walk, and came by himself to the hospital, suffering little pain except on sharp forward flexure of the thigh. The family and previous history of the patient were negative. He was a laborer in a motor-vehicle shop, doing much heavy lifting.

On examination the patient appears to be a well-developed young man with powerful muscles. There is nothing remarkable in his physical condition except locally. On inspection, the skin over the anterior spine of the ilium is slightly depressed; about 3 inches below the injury there is a slight discoloration. On palpation over this site the fingers find a point of tenderness and crepitus. Crepitus is obtained also by extending and flexing the patient's thigh. The fragment may be indistinctly felt displaced about 1 inch downward and apparently attached to the anterior fibers of the tensor fasciae femoris.

The diagnosis was confirmed by roentgenoscopy.

With the thigh flexed and slightly abducted, the fragment was replaced and held by means of a broad band of adhesive plaster passed tightly around the pelvis.

Treatment of Boils.—I have used the following mixture in my practice for seven years:

	gm. or c.c.		
Liq. potassii arsenitis	0	2	♏ iij
Liq. ferri peptonati cum mangano N. F., q. s. ....ad	5	0	ʒ j

This is a dose. Take after meals.

The taking of 8 ounces of the mixture has resulted in a prompt cure in every case, with no return of the boils.—LEROY E. CHAPMAN, M.D., Warren, Pa.

The Blind Leading the Blind.—Teaching sex-hygiene by people who do not even know the definition of "sex" is about on a level with quack advertisements of cures for all ills.—*Buffalo Sanitary Bulletin.*

Therapeutics

TYPHOID FEVER

(Continued from page 1459)

IMMEDIATE TREATMENT OF SUSPECTED TYPHOID

The symptoms of such a patient are usually more or less diarrhea, loss of appetite, a coated tongue, more or less headache, and considerable fever. There may be backache, muscle pains and a slight cough or mild bronchitis, with perhaps a history of nose-bleed and of more or less malaise or debility lasting for the previous two or more weeks.

Such a patient should receive a cathartic immediately, and none is better than calomel in a dose considered sufficient, *not* in divided doses. The hospital method of giving 1/10 of a grain of calomel every half hour. or hour. for ten doses is ordinarily very bad treatment. The digestion is more or less disturbed, nausea is more likely to be caused, and fretty, troublesome diarrhea is more likely to occur than with a single properly estimated dose of calomel. The following method of giving calomel is one of the best:

	gm. or c.c.		
℞ *Hydrargyri chloridi mitis* ...	0|20	or	gr. iij
Sodii bicarbonatis	1|0		gr. xv

M. et fac chartulam 1.
Sig.: Take at once.

It is best to give calomel either with a glass of milk or with a cup of tea or coffee, or with any other simple food. such as toast or crackers.

Castor oil administered by some more or less tasteless method will be as efficient as the calomel so far as the bowels are concerned, although the calomel perhaps washes out more of the old bile, and thus improves the condition of the liver.

While waiting for a positive diagnosis from the blood-test there is no reason why the patient should be uncomfortable from his high temperature or should suffer from his headache, and at this stage of uncertainty cold baths, spongings and even a trained nurse are entirely unnecessary, as many a patient shows these symptoms without typhoid fever being present. Therefore the following prescription is of value:

	gm. or c.c.		
℞ *Acetphenetidini*	1|50	*or*	*gr. xx*
Sodii bicarbonatis	2|50		*gr. xl*

M. *et fac chartulas* 5.
Sig.: One powder every four hours, unless the headache ceases and the temperature becomes low.

Presumably but two or three of these powders, at most, will be taken on the first day; the other two may be taken on the following day, if needed.

If a small dose of acetanild, as 0.1 gm. (2 grains), is preferred to the preceding dose of phenacetin, it may be used in the same manner.

The patient should receive very little food for the first twenty-four or forty-eight hours, but plenty of water. The food might consist of coffee and tea, toast, some simple broth or malted milk, or a little milk.

Even before the diagnosis is made the stools must be cared for so that infection of others may not occur.

TREATMENT AFTER THE DIAGNOSIS HAS BEEN CONFIRMED

Typhoid fever being established, absolute bed rest, no matter how mild the case may be, should be insisted on. The best possible room for the illness should be selected. The nurse should be the best obtainable, as the disease is typically one in which good nursing is more essential as a preventive of infection of others and as a preventive of complications than any sanitary orders that may be given or any medicine that may be administered. Proper hygienic and sanitary measures should be immediately inaugurated, and the board of health notified of the disease.

In a disease that is primarily so distinctly intestinal as is typhoid fever, the diet and the care of the bowels are of paramount importance. The diet has been sufficiently discussed above. The care of the bowels has been subject to a great deal of discussion. The nearer surgical cleanliness is obtained in the intestine if typhoid ulcers are present the better will the patient do. If the bowels are properly moved there is less putrefactive substances in the intestine, there will be less bacteria and their toxins, less absorption of such toxins, and therefore less fever, less cerebral disturbance such as delirium and insomnia; there will be better nutrition, less liver disturbance, less likelihood of kidney disturbance, less likelihood of the colon bacillus migrating and adding its disturbances to that of the typhoid bacillus, less tympanites, or absence of tympanites if the management of the bowels is properly maintained, and with this absence of tympanites greatly diminished danger from hemorrhage and perforation, and less likelihood of cardiac failure. It should be reiterated that tympanites, once supposed to be a constant symptom of typhoid fever, is abnormal to it, if the diet is correct and the bowels are properly managed. And it is the tympanites that causes disturbed respiration, heart failure, such stretching of the intestines as to cause danger of tearing apart of the ulcerated tissues, and consequent hemorrhage; or the pressure may cause perforation through the base of an ulcer and consequent peritonitis; besides, the increased intestinal pressure promotes unnecessary absorption into the lymphatics and blood-vessels of the intestines. Tympanites is pernicious in typhoid fever, and if it occurs there has been some mistake in the orders of the physician or in the management by the nurse. Case after case of typhoid fever may be carried through its course from start to finish with a soft, flattened abdomen.

Any particular food selected that seems to cause tympanites or indigestion should be stopped, and some other nutriment substituted. The bowels should be moved daily by artificial means, and not as a diarrhea. Diarrhea should not be tolerated. The physician should cause the bowels to move, and then prevent fretty, frequent bowel movements. These, however, will often not occur if the bowels are daily properly moved. A good method of causing these movements (not the only method) is to administer a compound of aloin tablet every other night, with one of the feedings, so that it will not be taken on an empty stomach. A good combination is as follows:

	gm. or c.c.		
℞ · Aloini	0|02		gr. 1/3
Strychninae sulphatis	0|0015	or	gr. 1/40
Pulveris ipecacuanhae	0|03		gr. 1/2
Extracti belladonnae foliorum	0|006		gr. 1/10

M. et fac capsulam (or tabletam) 1.
Sig.: One capsule at night.

An active preparation of cascara may be substituted for the preceding, as 3, 4, 5 or 6 grains of the extract in a good tablet. Neither aloin nor cascara irritates or causes inflammation in the intestines, and the increased peristalsis that they cause is nothing like as severe as will be caused by the irritation of the intestine from imperfectly evacuated fecal matters. Of course, if the intestines are allowed to become more or less paralyzed by prolonged tympanites, it may be at first difficult to start the bowels to move properly with simple laxatives.

After the bowels have moved once thoroughly or twice in ordinary amount, the patient should receive 1/10 grain of morphin. This will be sufficient to check the peristalsis and stop more movements for perhaps nearly twenty-four hours.

On the alternate day the patient should receive a rectal injection of an ounce of glycerin and an ounce of water. This will cause complete evacuation of the large intestine. If for any reason the bowels do not move on the day following the administration of the aloin, the glycerin enema may be given on that day.

The subject of bowel antiseptics is another one that has caused a great deal of discussion, and especially as to their value in typhoid fever. Dilute hydrochloric acid has been advised, not only because it aids digestion, but also because this physiologic acid increases the normal secretions of the intestines and makes digestion better, and while in the stomach it is of course an antiseptic. If the fever is severe and the patient is seriously ill, in all probability the hydrochloric acid in the stomach is not properly secreted. Certainly, a sour drink consisting of five drops of dilute hydrochloric acid in a wineglass of water, after the protein meals, may often be advisable. Iodin in small doses has been used, and various forms of creosote and other phenol preparations, but most of these seem inadvisable as all more or less tend to cause irritations, and the strong phenol preparations tend to irritate the kidneys.

One of the most satisfactory bowel antiseptics is phenyl salicylate (salol), because it is inert in the stomach and does not break up into its component parts (namely, salicylic acid and phenol) until it reaches the upper intestine. How far down the intestine such antiseptic action is active cannot be stated, but that it does some good there can be no question. Such activity may be demonstrated in all acute diarrhea attacks. It certainly prevents fermentation.

The dose of salol to be given in typhoid fever should be small, because it should be long continued. A capsule containing 0.20 gm. (3 grains) given once in six hours is sufficient, and of value. If albumin appears in the urine, the salol should be stopped.

Many times the administration of yeast, as above suggested, will not only act as a laxative, but will prevent fermentation in the intestines and sometimes clean a badly coated tongue. If yeast is given, salol should be stopped, as the two activities should not be combined, the salol being likely to inhibit the activity of the yeast fungus.

If for any reason the salol should be stopped, and perhaps always when convalescence is about to begin, or perhaps throughout the illness more or less constantly, hexamethylenamin (urotropin), on account of its antiseptic action during excretion by the kidneys, should be given perhaps in 0.30 gm. (5-grain) doses, dissolved in half a glass, or more, of water, and administered three times in twenty-four hours. It is quite probable that this drug may prevent typhoid bacilli from obtaining a harbor in the gall-bladder and in the kidneys, the two regions that are most likely to show typhoid bacilli long after convalescence, but recent investigations indicate that there is no reason to attribute to it antiseptic powers in cavities or tissues whose reaction is alkaline or neutral. It is rare that this drug causes any irritation of the kidneys or bladder, but, if it does the drug, of course, should be stopped.

The management of the temperature in typhoid fever is one of the most important problems. A continuous high temperature will surely waste the patient's body and vitality. Not only does the fat disappear and the skeletal muscles degenerate, but the vital organs of the body become impaired, and more especially a myocarditis develops with consequent impaired circulation.

Of course the best way to treat this high fever is to prevent it, and the diet and care of the bowels above outlined will and does very many times prevent high temperature. Good sleep and fresh, cool air, perhaps aided by an electric fan, and thin bed-coverings are of aid in lowering the temperature. A restless patient, suffering from more or less insomnia, will always have an increased temperature. No drugs to lower the temperature should be given after the first day or two. The only active measures advisable are hydrotherapeutic. The severity of the tub bath is inexcusable, and under any circumstances the measure could rarely be carried out properly in a private house. The value of other strenuous hydrotherapeutic measures is also questionable. In fact, even the value of ice sponging has probably been overestimated. Sponging with tepid water, or with water a few degrees below the body temperature, is probably generally as efficient as is cold sponging in reducing the temperature, if one takes the whole twenty-four-hour temperature into account and not the immediate drop. The discomfort caused by and the dread of ice-water sponging and the reaction that must occur almost discounts its good effects. Tepid sponging need not be used more frequently than once in six hours. Sponging with iced water every three hours if the temperature is above 101.5 or 102 is cruelty without equivalent results.

A coil on the abdomen through which is running iced water is often of value, and causes no distress or discomfort after the first hour or two. Iced or cold compresses to the abdomen are of advantage. They diminish the temperature and tone the circulation by causing contraction of the abdominal vessels, and increase peristalsis and cause evacuation of gas. But even this simple measure should not be used unless the temperature is above 102.5 at least, and perhaps only when it is above 103.

The value of the ice-cap is doubtful, unless there is actual meningitis. Prof. H. G. Barbour[3] showed that when cold was applied to the brains of rabbits the temperature was increased, while when heat was applied the temperature was depressed.

This physiologic finding is worthy of very careful clinical consideration. The ice-cap is generally a discomfort, and it probably seriously interferes with the nutrition of the hair, and is one of the causes of loss of hair after fever.

Multiple Pregnancies.—A Mexican exchange reviews the cases of multiple pregnancy on record, citing M. Baudouin to the effect that there are six known cases of a sextuple pregnancy (1904), and reporting further an authentic case in a Mexican town in 1911. Dr. N. Leon of the Morelos Hospital of Morelia, State of Michoacan, Yucatan, then reports that a creole woman of 27 in his town at her second pregnancy after an interval of nine years aborted and expelled twelve fetuses, labor and the puerperium being entirely normal. The family buried the fetuses, but they were dug up by the police and are now preserved in the museum; they measure 2 inches each. Leon was told that there was a single placenta for the whole.

THE CONVERSION OF CARBOHYDRATES INTO LACTIC ACID IN THE TISSUES

The average person consumes about a pound of carbohydrate a day in his diet. This is no small contribution to the body's transactions, and calls for reactions of considerable magnitude to convert this nutriment to its proper uses. Yet so accustomed are we to think of the foodstuffs as being "utilized" or "assimilated" or "converted" or "burned up" in some semimysterious fashion to meet the exigencies of every physiologic situation that few persons, even among those trained in the school of nutrition study, stop to consider precisely what the metabolism of each of our standard nutrients actually involves. What are the successive chemical transformations to which sugar, protein and fat are subjected prior to the elimination of their waste products? And the student of medicine will add to this query: What are the *perversions* which these reactions may experience under what is designated as pathologic disturbance?

That carbohydrates ordinarily leave the alimentary tract and enter the circulation in the form of relatively simple compounds—the hexoses or six-carbon sugars—is now generally accepted. The sugars of which glucose affords the most familiar type are preeminently the physiologically "available" or usable carbohydrates. Information as to what happens to them in the tissue laboratories has been sought by a variety of methods, each of which has been more or less fruitful. One may feed large quantities of carbohydrates to the normal or diabetic organism and search for fragments which have escaped complete transformation. Again, conjectured intermediate products may be furnished to the organism and their fate pursued. By this plan it has, at any rate, been demonstrated that the sugars are not directly burned up without further cleavage in the body; for such primary oxidation products as one might expect from the sugar are not readily used in the organism. They are represented by saccharic, mucic and oxalic acids, all of which act more like poisons than like normal stages in the combustion of our food sugars. The method of perfusing isolated organs with carbohydrates and searching for the products which arise, so to speak, at the seat of their formation has also been tried. But Drs. Levene and Meyer[1] of the Rockefeller Institute for Medical Research in New York have successfully employed a still different plan, that of studying the direct effect of tissue extracts or isolated tissues themselves on carbohydrates. Some time ago they demonstrated in this way that hexoses (such as glucose) can be dissociated by the action of leukocytes on them and in this manner converted into lactic acid. Much interest has centered in this evidence. Lactic acid has long been suspected to be an intermediate product in the metabolic transformations of carbohydrates. It is rapidly formed by the cleavage of the glucose molecule, and readily by the action of bacteria. Some French writers, notably Lépine,[2] have been inclined to attribute to leukocytes the function of sugar decomposition in the living organism. But Levene and Meyer have now shown further that the same conversion of various simple sugars—glucose, mannose, fructose—into lactic acid can be accomplished by different isolated tissues under aseptic conditions. All three of the hexoses enumerated yield the same lactic acid. These excellent researches make it more than probable, therefore, that this mechanism of lactic acid formation is identical in all tissues. They mark a long step toward a more intimate understanding of how the cells act.

RECENT WORK ON RABIES

Within a short time several articles giving important results of investigations on rabies have been published in this country. Brief reference may be made to some of these results, particularly those that bear on two great problems of rabies, namely, the nature and cultivation of its virus and the curative treatment of the active disease.

Heretofore investigators have availed themselves of the brain and spinal cord as sources of the rabic virus for various purposes; very little has been done with the virus as it exists in the salivary glands. Poor and Steinhardt[3] have succeeded in securing from the salivary glands of infected dogs virus free from the cells of the host and from contaminating organisms. They have made use of two methods for this purpose: (1) extraction of the glands with glycerin, and (2) subjection of the glands in distilled water to a vacuum of 29 inches of mercury for an hour, the fluid thus obtained, to which is added the juice pressed out of the aspirated glands, containing the virus after filtration through Berkefeld filters. No differences have been found between this virus, which is in what we may call a pure state, and the virus in the brain and spinal cord.[4] Microscopically the salivary virus as obtained by extraction or aspiration shows no definite, formed elements, only small granules, and the question of the Negri bodies and their relation to the virus confronts us. Poor and Steinhardt suggest

4. Poor and Steinhardt: Jour. Infect. Dis., 1913, xiii, 203.

that possibly the chromatin elements in the Negri bodies represent the virus, the other parts being possibly products of reaction on part of the nervous tissue. As yet no announcement has been made of the successful cultivation of the salivary virus, which would seem to be a promising material for experiments. The survival of the virus in glycerin does not signify that it necessarily is of protozoan nature because, contrary to current statements, Poor and Steinhardt find that bacteria such as the diphtheria bacillus and the tubercle bacillus also survive glycerin treatment.

Noguchi,[3] Moon[4] and Williams[5] report the results of experiments in cultivating the virus of rabies as obtained from the nervous system. Noguchi announces that he has succeeded in growing various forms of virus which appears in the cultures as granular and pleomorphic chromatoid bodies, some of which are surrounded with membranes, and that he has reproduced the disease by inoculating animals with cultures. Williams raises the point whether the successful inoculation of animals may not have been due to the presence of the original material rather than to the results of active growth of a specific organism. No doubt this point will be settled definitely before long. Williams and Moon describe experiments in growing the organism of rabies outside the body in brain-tissue under various conditions, and both succeeded in producing rabies in animals with fourth or fifth generation or transfer of such cultures. Both investigators are inclined to believe that growth took place. The indications, then, are that before long the artificial propagation of the virus of rabies will have been accomplished satisfactorily. When that is done the relation of the Negri bodies to the disease and their nature as well as the nature of the organism itself and its relation to the seemingly invisible virus in Poor and Steinhardt's cell-free and bacteria-free salivary products undoubtedly will be made clear.[6]

While such fine progress is being made toward the solution of the problems of the nature and cultivation of the cause of rabies, the hope of finding a specific remedy for the disease naturally awakens. Perhaps a remedy already has been found! A short time ago Moon[7] reported that quinin sulphate by way of the stomach cured the active disease in inoculated dogs. And now Harris,[8] who has done important work on the use of frozen and dried virus in the preventive treatment of rabies, reports the recovery of a patient with rabies after injections of quinin. Unfortunately, the case is complicated with symptoms of alcoholic delirium, and at all events further trials are necessary to determine the value of quinin in rabies. The hopelessness of the prognosis of rabies warrants unreserved, thorough trial of quinin as promptly as possible. Cases of the disease occur every now and then in various parts of the country, and a long time should not elapse before we can learn whether or not the disease is amenable to quinin. Further and extended experimental work is indicated because the question may arise whether or not quinin given during the incubation period will prevent the disease. Just now the outlook in regard to rabies seems altogether hopeful.

SUGAR COMBUSTION IN PANCREATIC DIABETES

We have of late repeatedly referred to the problems of sugar metabolism in diabetes, because in ultimate analysis the rational therapy of this disease must be based on an exact knowledge of the reason for the waste of unused carbohydrate. The two prominent views at present entertained by students of the subject are quite at variance with each other. In so far as they apply to the type of diabetes supposedly involving a disturbed pancreatic function, both theories admit that the metabolic upset may be conditioned by the loss of some internal secretion of the pancreas. They differ in assuming in the one case that the combustion of carbohydrates fails completely when the pancreas is out of commission, and in the other that the capacity to burn sugars is by no means lost, but that there is rather an overproduction or excessive mobilization of carbohydrate which leads to hyperglycemia and subsequent glycosuria.

When Knowlton and Starling[1] succeeded last year in showing that the perfused isolated hearts of animals are no longer capable of using sugar in the normal manner after the pancreas has been extirpated from the subjects and they have become diabetic, it seemed as if a clear-cut answer to the debated question had at length been arrived at. Here was a striking demonstration of the inability of the muscle of the diabetic to burn sugar in the way that the normal heart muscle can. Furthermore it appeared to be possible to restore in some degree the metabolic power of the muscle toward carbohydrates by resorting to the addition of suitable extracts of pancreatic tissue (presumably containing the hypothetic pancreatic "hormone") to the heart-perfusion fluids.

The critics have not been content with this solution of the controversy. Even assuming that the diabetic heart has lost its capacity for utilizing carbohydrate, it does not necessarily follow, they properly remind us, that the entire diabetic organism behaves in the same defective way. Perhaps other organs of the body, like the liver, can still manage to use carbohydrate freely, as von Noorden[2] and his followers have lately taught. It became desirable, therefore, to investigate the metabolism of carbohydrate on the entire intact animal as well as on an isolated organ.

The administration of sugar to an animal is speedily followed by the preferential combustion of carbohydrate and manifests itself in a characteristic "respiratory quotient" or relation of carbon dioxid produced to oxygen absorbed. Unusual muscular activity must be excluded or taken into account, since this of itself may affect the quotient. Appropriate experiments can be carried out only in specially equipped nutrition laboratories; but the result—the fact of a high respiratory quotient after carbohydrate utilization—is readily interpreted by any one. The crucial experiments on the question here at issue have been conducted by Dr. Verzár and von Fejér[3] in Tangl's laboratory at Budapest. Their conclusion is clear-cut. When sugar is injected into depancreatized and therefore diabetic dogs the expected rise in the respiratory quotient indicative of carbohydrate combustion does not manifest itself. This is true, however, only when the diabetic condition has definitely established itself. Evidence of some unimpaired power of utilizing the sugar may still be obtained in the first few days after removal of the pancreas, but not at a subsequent period.

More recently Drs. Murlin and Kramer[4] of the Cornell University Medical School in New York City have confirmed the fundamental fact of the loss of ability to burn sugar in the case of depancreatized dogs. Neither extract of pancreas alone nor the double extract of pancreas and duodenal mucosa nor the transfusion of normal blood produced, within the time of maximal effect on the glycosuria, any effect on the respiratory quotient which could be interpreted as an index of increased combustion of carbohydrate.

It matters not that the Hungarian physiologists were unable to restore the metabolic efficiency of their depancreatized animals by *transfusion of normal blood from* healthy subjects or by infusion of various sorts of pancreatic extracts. The experiments tend definitely to confirm the important earlier conclusions of Knowlton and Starling,[5] and support the view that sugar is no longer satisfactorily used under the circumstances that obtain in such diabetic subjects.

THE RELATION OF THE LIVER TO DIFFERENT SUGARS

In recent years varied attempts have been made to apply the results of sugar feeding in the functional diagnosis of liver disease. In principle the process consists in administering a relatively large dose of some simple soluble carbohydrate such as glucose, levulose or galactose at one time and ascertaining by examination of the urine to what degree the sugar has been retained in the organism and presumably utilized. Trials of this sort on both man and animals have shown that the "assimilation limit" is reached with much smaller doses in the case of galactose than with the other sugars mentioned; and further, levulose is less readily utilized than glucose, the physiologic sugar. The practice here outlined rests on the theoretic assumption that these carbohydrates all are metabolized, either by conversion to glycogen or otherwise, in the liver, the organ to which they are immediately conducted when they leave the alimentary tract. Defective liver function should accordingly reveal itself by a limited capacity to utilize carbohydrates when they are furnished in great abundance at one time.

On the whole, the experience with these "functional tests" has been rather disappointing. Perhaps this can be in part explained by recent observations made in the medical clinic at Heidelberg.[1] The participation of the liver in nutritive functions can in good measure be excluded by surgical intervention in the form of the well-known Eck fistula, whereby the portal circulation is side-tracked from this organ and diverted directly into the general venous circulation of the vena cava. When this is done there is, according to Draudt,[1] no noteworthy difference in the utilization of glucose and levulose as compared with that in normal animals. The assimilation of lactose and galactose, on the other hand, tends to be markedly diminished. It seems logical to assume, in the absence of further evidence, that the liver occupies a place of special prominence in the utilization of the latter sugars. They need to be chemically "rearranged" before they can be converted into the typical storage carbohydrate glycogen; and apparently the liver retains the capacity for such more intricate chemical transformations in greater degree than do the other tissues. It follows *therefore that galactosuria may be in large measure* dependent on the extent to which the participation of the liver in metabolism is excluded and that this symptom may be taken as a measure of the diversion of the portal blood from its usual channels. Corresponding with these findings it has been noted that the sugar content of the blood of animals bearing an Eck fistula is increased when lactose or glucose is administered to them, though normally they show no tendency toward hyperglycemia. It is not unlikely, therefore, that renewed attention to the behavior of galactose in the organism under various conditions will repay those who are interested in functional tests of the sort described.

THE RIPENING OF FRUITS

The place which fruits are assuming in the dietary of man is one of growing importance. Certain species, like the apple and pear, the plum and the grape, have long enjoyed a deserved popularity; others which were once among the rarities in the United States are now finding wide-spread favor. This applies in particular to some of the forms of melons and to the fruits which are usually shipped by water from the tropical regions where they are grown to the centers of distribution. Bananas, which were found only in a few seaboard towns a generation ago, are now common in every region of America. In Great Britain, where they were little known less than two decades ago, they have now almost become the "poor man's fruit."

[5] Criticisms offered by Macleod and Pearce of Western Reserve University (Centralbl. f. Physiol., xxvi, No. 26) have been taken into consideration by Verzár and von Fejér.

[1] Draudt, L : Ueber die Verwertung von Laktose und Galaktose nach partieller Leberausschaltung (Ecksche Fistel), Arch. Exper. Pathol. u. Pharmakol., 1913., lxxii, 457.

The ripening of fruits plays so important a part in their availability and in some of the problems of transportation that authentic information on this subject is much to be desired. Some fruits, like the apple, may be allowed to ripen almost fully on the tree and may be kept in the ripened condition for relatively long periods if proper attention is paid to their manipulation and storage. Other fruits, like the berries, cannot be kept in the ripe condition very long before deterioration and decay set in. In still other cases, as with the banana, the fruit may be picked and transported advantageously before the final ripening has begun; and this process can then be controlled in the market and home as the conditions demand.

The physical changes, like the variation in color of ripening fruits, are familiar, since they are evident to the senses; but these alterations are merely indicative of changes in the chemical make-up of the fruits under the conditions which determine ripening. Heat, moisture, air and light may all participate in determining the characteristic changes that ensue. Laboratory investigations in recent years[1] have given clearer indications of what takes place. Among the reactions easier to follow are the transformation of starch into sugar, the conversion of soluble tannin compounds with their astringent properties into insoluble forms, the actual lessening of the quantity of acid, or the masking of the acid flavor by the accumulation of sugar, the softening of woody tissue, and the increase and storage of water (juice). The formation of compounds, such as volatile ethers, organic oils, etc., responsible for special flavor and aroma is not so easy to follow.

One reason why ripening processes can so often proceed advantageously after removal of the fruit from its parent plant lies in the fact that many of the physical and chemical changes noted are carried out by unorganized ferments or enzymes. These are readily influenced by temperature, etc.; hence the importance of the latter in varying the speed at which the ripening proceeds. This may even continue so long as to carry the change to an undesirable point known as after-ripening, which is not ideal from the point of view of the consumer. During the ripening the fruits also undergo a sort of respiration in which oxygen is consumed and carbon dioxid produced. In this process part of the carbohydrate is oxidized and heat is generated.

With the growing knowledge of what the ripening of fruits really involves we are certain to acquire better criteria of what a properly ripened product should really be. The fact that unripened (winter) apples are unfit for consumption in the early fall because instead of sugar they have a large content of raw starch and other objectionable ingredients which disappear with the "mellowing" process, will be understood in a more intelligent way than has usually been the case. Furthermore, the facilitation or other regulation of the natural processes of ripening by artificial means will make it possible to dispel the limitations hitherto placed by seasons or distance. The beginnings are already apparent in the practices of modern commerce.

TEMPERATURE AND HUMIDITY IN HOSPITALS

Americans are inclined to pride themselves on the ingenuity they exhibit in the construction of public buildings and on the novelty and up-to-date character of the devices introduced. Plumbing and heating systems, elevators and telephones, lighting and cooking devices are pointed out in exemplification of the newest that the mechanic arts and skilful labor can provide. In our emphasis of the mechanism we are all too prone to overlook the man; for it is on the human brain that the successful working of all these varied arrangements ultimately depends. The only completely satisfactory automaton is the human individual.

These reflections are prompted by observations which Miss Lake has recorded in regard to the temperature and humidity in six New York hospitals.[1] There, if anywhere, one would expect the hygiene of heating and ventilation to be mastered in the highest degree. Yet the statistics gathered show that the control of temperature is more a question of management than of the system employed. In two hospitals, one with window ventilation and the other with a plenum system, a uniform temperature was regularly maintained despite the difference in the systems employed. Other institutions showed wide variations in temperature. One hospital was "consistently overheated"; for certainly we are not inclined to regard temperatures between 75 and 80 F. as desirable. Miss Lake points out the high temperatures in the children's wards and operating-rooms of almost all the hospitals investigated. In the case of the places for operation the reason is forthcoming; but whether temperatures between 70 and 80 should be maintained in children's wards is debatable. Certainly it is questionable whether a ward with a day record of 76 F. should be allowed to cool to 57 at night unless special precautions are taken for the protection of children who persist in sleeping uncovered. As a commentary on the wisdom of management in the placing and regulating of thermostats it may be noted that an operating-room with a temperature of 88 F. registered 98 F. on the thermostat placed against a wall back of which were the steam-pipes of a sterilizer in an adjoining room.

[1] Langworthy, C. F., and Milner, R. D.: Some Results Obtained in Studying Ripening Bananas with the Respiration Calorimeter, Yearbook, U. S. Dept. Agric., 1912, p. 293.

[1] Lake, Alice L.: Temperature and Humidity in Certain New York Hospitals, Jour. Home Economics, 1913, v, 301.

Low humidity is a rule in hospitals and strikingly so in the operating-rooms. Of the seventy-five records taken by Miss Lake, sixty-seven were between 20 and 45 per cent. relative humidity. This is, of course, due to the high temperatures; for the outside humidity reaches far higher figures. It matters not whether this more humid outside air is brought in through windows and ducts or not; for the warming of the air to the high room-temperatures has a drying effect. Whether or not it is advantageous for patients in an operating-room or in the wards to be subjected to dry heat may be debatable. The only suitable way to alter the situation is to provide artificial humidification. As for the perversions of temperature and humidity, they appear to depend on the inefficiency of the man in charge rather than the system installed.

THE URINE IN NORMAL PREGNANCY

The important research by Murlin and Bailey[1] on the protein metabolism of normal pregnancy should serve to dispel some of the illusions current in regard to supposed perversions of nutrition frequently connected with the late period of gestation. Much attention has been centered in the past on the ammonia output in the urine of pregnant women. Inasmuch as high ammonia output, when correctly interpreted in relation to other findings, may indicate the existence of abnormal metabolic conditions, it is, to say the least, essential to have reliable statistics as to what is to be considered the normal and what constitutes a deviation therefrom. It happens that for the most part the data for the output of ammonia nitrogen in the urine have in the past been expressed in percentages of the total nitrogen excretion. This mode of presenting results of urinary analysis has obvious shortcomings: for if, as is commonly true, the absolute ammonia output remains fairly constant from day to day, the percentage output will nevertheless vary widely whenever the total nitrogen metabolism varies. For example, assuming the daily ammonia nitrogen excretion to be constant at 0.5 gm., the percentage output will be quite different under conditions in which the day's urine contains 5 or 15 gm., respectively, of nitrogen. Low excretion of nitrogen raises the percentage of ammonia output. The chemist appreciates these points well enough; but the clinician taught to respect the percentage figures and to see a menace to his patient when they are unduly high too often fails to realize that 10 or 12 per cent. of ammonia nitrogen may merely mean that the subject has eaten less, or stored more protein and therefore excreted less nitrogen waste.

Murlin and Bailey have found that in a perfectly normal pregnancy and puerperium the percentage of ammonia nitrogen in the urine before and after labor shows but slight differences and lies within normal limits (from 4 to 6 per cent.) except for one or two days following normal delivery, when it is slightly increased (from 7 to 10 per cent.). The ammonia nitrogen in perfectly normal pregnancies, in which the retention of nitrogen is large and the total nitrogen in the urine consequently small, may range as high as 12 per cent. of the total and be unaccompanied by any unfavorable symptoms. Immediately after severe catharsis it may reach the height of 17 per cent. because of the diminished absorption of nitrogenous food from the alimentary tract and consequently diminished excretion of total nitrogen. But the absolute amount varies only slightly from day to day and previous to delivery never exceeded 0.88 gm. in urine known to be uncontaminated. From this the Cornell investigators are inclined to look on any amount up to 0.012 gm. ammonia nitrogen per kilogram of body-weight in the twenty-four-hour urine as well within normal limits. It further appears that some of the instances of high ammonia output hitherto reported were in fact due to contamination of the bladder whereby ammonia arose in the urine itself as the result of microbial changes. In such cases irrigation of the bladder twice a day with a saturated solution of boric acid caused prompt reduction in the ammonia figures, the food and total nitrogen remaining the same.

So much has been asserted in the past regarding supposed deviations from the normal in this period, so much emphasis has been placed on the dangers prognosticated by a high ammonia percentage, that it is a satisfaction to learn the conclusion reached by Murlin and Bailey. In general, they believe that peculiarities in the composition of the urine of normal pregnancy as regards its nitrogenous constituents may be accounted for on purely physiologic grounds.

Current Comment

CLEAN HANDS

The assertion is sometimes made that it is alone the "filthy habits" of the typhoid carrier that make him a public danger. If he could be made to wash his hands, it is alleged, transference of infection would be prevented. Those who regard bacterial cleanliness as simply a matter of careful hand-washing are likely to obtain disappointing results if a recent experiment performed by Cummins[1] is at all indicative of what may occur under ordinary conditions of life. This observer, after dipping the right index-finger in the urine (proved to contain upward of 3,000 million typhoid bacilli per cubic centimeter) of a typhoid carrier, proceeded to carry out measures of cleansing as follows:

1. Rinsed in liquor cresolis compositus solution (approximately 2 per cent.). 2. Then held the finger under the tap, rinsing first in cold, then in very hot water (temperature not

---

[1] Murlin, J. R., and Bailey, H. C. Further Observations on the Protein Metabolism of Normal Pregnancy, Arch. Int Med., September, 1913, p. 288.

[1] Cummins: Jour. Roy. Army Med. Corps, 1913, xx, 657.

recorded). 3. Washed very carefully in about 0.5 c.c. of sterile water in a watch-glass, and plated the whole of the water used for this purpose. Result: Three hundred and thirteen colonies of *Bacillus typhosus* on the plate. 4. After the washing in sterile water mentioned, the tip of the finger was thoroughly soaked in absolute alcohol, allowed to dry, and the washing in sterile water repeated. The "washings" were again "plated." Result: Four colonies of *B. typhosus.*

Even when the fingers are thoroughly rubbed with a towel and the danger of finger infection thereby lessened, it is obvious that the towel in its turn may become infected. The sort of accident that may follow from such conditions is illustrated by another observation of the same author:

> On Sept. 26, 1912, 100 c.c. of soup freshly prepared from the "stock pot" was placed in a china bowl, no attempt being made to sterilize the bowl or to cover it from the air. The tip of the experimenter's right index-finger was allowed to come in contact with the urine of Carrier A (proved by plating to contain upward of 3,000 million of the *B. typhosus* per cubic centimeter). The china bowl was then lifted in such a manner that the infected finger came in contact for a moment with the contained soup. The soup was left at room temperature with free access of air and dust to the open bowl. On September 27, enumerated the bacterial contents of the "soup." Result: *B. typhosus* was present apparently in pure culture, numbering 15,500 per cubic centimeter.

Such facts as these add strength to the agitation for better supervision over the conditions of those persons engaged in serving and preparing food for large numbers of people. The action of the Pennsylvania Railroad in providing for the systematic inspection of all of its employees in the restaurant and dining-car systems has already been noted.[2] This example should be followed by the management of other organizations engaged in the handling and serving of food on a large scale. Social clubs and similar bodies, as pointed out by a correspondent recently,[3] are often lax in this regard. The supervision of cooks and waiters in dining-cars, hotels, restaurants and clubs is certainly a matter that deserves more attention than it has yet received. "Defective plumbing" is far less important.

POSTGRADUATE MEDICAL EDUCATION IN THE UNITED STATES

Last week there appeared the announcement[4] of some postgraduate courses to be offered under a joint arrangement by several educational and research institutions in New York City. It is not the mere fact that more postgraduate courses are being offered that deserves comment, but that several institutions having such courses to offer have seen fit to unite in having those courses given under a single control to the mutual advantage of both teacher and learner. It would eventually be to the advantage of all concerned if all the various postgraduate courses now being offered in our medical centers could be brought under a centralized control. As the courses are given at present, the graduate student has much difficulty in finding out from the multiplicity of agencies just what courses are available; he perhaps spends still more time in locating the courses desired and then often finds to his disappointment that several of the courses he has selected conflict so seriously that he cannot take them without spending much more time than he feels he can spare from his practice. Under the centralized administration there would be one place where the student could secure full information regarding all courses offered; one circular could be issued describing all courses; the courses could be so arranged as to avoid conflicts between related courses; the present confusion and conflict would give way to system and order; much duplication of expense could be avoided, and—most important—a greater number of physicians would be attracted to the courses. There is probably as great an abundance of clinical material in several of the large cities in this country as is to be found in the continental cities of Europe, and doubtless some of the courses offered are as excellent or even superior. The great need, however, in each of our large cities is for the centralized control which is essential for the best development of those courses. Harvard, with its new Graduate School of Medicine, has made an excellent start by forming a close affiliation with many of the hospitals of Boston. And now several institutions of New York are giving these postgraduate courses under a unified administration. This will surely render the courses more attractive and valuable to physicians, and a greater number of physicians will take the work to the mutual benefit of themselves and of their patients.

THE MECHANISM OF VOMITING

Vomiting is regarded by many merely as a sort of antiperistalsis of the stomach and esophagus. There is evidence, however, that phenomena characteristic of emesis can follow even after removal of the entire gastro-intestinal tract, when emetic substances like the digitalis compounds are administered intravenously.[1] The part played by the digestive tube in the act of vomiting has been further elucidated by roentgenologic observations on the movements of the alimentary tract after administration of apomorphin.[2] In dogs the process of vomiting exhibits three distinct phases: First, the pyloric portion of the stomach contracts and fills the relaxed fundus with contents; then, as the cardia opens, food materials are projected through it into the esophagus by the contractions of the diaphragm and the abdominal muscles; finally, after varying intervals of rest, the esophageal contents are forced to the exterior by expiratory movements. During their sojourn in the esophagus the food particles are propelled up and down therein by the characteristic respiratory activities. The cardiac sphincter frequently remains open and the gullet is relaxed. It should be emphasized that at no time was antiperistalsis of the stomach or esophagus observed in Hesse's experience. The act of vomiting is not always a completed process; frequently the gastric contents are moved into the esophagus but not conveyed to the exterior. Even when typical emesis occurs, the gullet is rarely emptied entirely. The residual débris glides back to the cardia, where it may remain for some time and finally be returned to the stomach itself. Thus the evidence is accumulating to show the participation of nonalimentary muscles in the act of vomiting; and in place of the supposed dominant importance of purely local stimuli in the gastro-intestinal canal the significance of the vomiting center in the medulla, from which large groups of contributing factors can be controlled through nervous channels, is assuming a conspicuous place.

THE NARCOTIC ACTION OF MAGNESIUM SALTS

The now widely familiar method of inducing narcosis by the subcutaneous injection of magnesium sulphate (Epsom salt), introduced some years ago by Meltzer and Auer, is capable of producing a profound depression of the animal organism. If the proper dosage is employed all reflexes and signs of sensibility are lost for a time, while respiration remains intact. It has been urged against the procedure as an anesthetic device that the magnesium salts merely paralyze, and that sensation is by no means lost. Indeed, the action has been compared directly with that of the classic poison curare, in its familiar manifestation of paralyzing the motor-nerve endings. Meltzer and Auer[1] have now brought new evidence that magnesium salts affect also the central nervous system. They have found that when experimental animals receive one-half or less of the effective narcotic dose of magnesium sulphate they are readily narcotized deeply by inhalation of small doses of ether which are of themselves insufficient to narcotize normal animals. If the magnesium had only a peripheral effect, which is asserted by those who hold that it merely paralyzes the motor-nerve endings, it is highly unlikely that there could have been a summation such as just described with the subminimum central effect of the ether. In the absence of more compelling evidence, therefore, the condition of depression induced by magnesium may still be regarded as one of anesthesia in which there is an inhibition of the entire nervous system, not alone its peripheral branches.

A CLEAN RECORD IN THE CANAL ZONE

Those who have been following the remarkable record of the work of sanitation of the Isthmian canal, and have watched the gradual reduction of the death-rate and the elimination of preventable disease, have hoped that before the monumental work of constructing the canal was finished it might be possible for Colonel Gorgas to present a report that would be clean as far as death from disease was concerned. The report of the Department of Sanitation for the month of August, 1913, just received, shows that during that month there were thirty-nine deaths from all causes among the employees of the canal commissioners. Of these, one, a Peruvian, died of malaria; another, a Spaniard, of alcoholism, and the third, a Greek, of appendicitis. The only deaths among white Americans which occurred during the month were two from violence, one due to an accident on the railway and the other to an accident in the quarry. Among the 12,481 white American men, women and children on the Isthmus connected with the commission—that is, employees and their families—not a single death from disease occurred. The exodus from the Canal Zone has already begun; those employees whose work has been completed are returning to the United States with their families. The number of the American citizens resident in the Canal Zone will probably decrease steadily in the future. It is a fitting climax to the work of Colonel Gorgas, which has challenged the admiration of the civilized world, that the month which probably marks the high tide of American occupancy of the Canal Zone should have passed without a single death from disease in the American colony.

ACIDOSIS IN METHYL ALCOHOL INTOXICATION

In various discussions of the toxicity of methyl alcohol which have been conducted in THE JOURNAL[1] since the now celebrated series of fifty-seven fatal cases of poisoning among the inmates of a home for the poor in Berlin early in 1912, it has been pointed out that inasmuch as the compound is in part oxidized to formic acid in the body this oxidation product may be an immediate cause of the toxic symptoms. It has been maintained that the salts of formic acid are not particularly poisonous to the organism. If, however, we assume that formic acid is liberated as a free acid which is not readily further oxidized, it is quite conceivable that it may give rise to symptoms of acid poisoning precisely like some other organic acids, notably beta-oxybutyric acid. One feature of the harmful effects of methyl alcohol ingestion, on this hypothesis, would be the acidosis developed by its oxidation product. Normally such organic acids formed in disturbed intermediary metabolism are neutralized by ammonia in the body so as to spare the store of fixed alkalies which are present. A high output of ammonia in the urine is accordingly an index of a condition of acidosis. The theory here evolved and originally suggested in the case of methyl alcohol intoxication by Schmiedeberg has been put to a test in his laboratory by Król.[2] His experiments show clearly that the administration of methyl alcohol to animals is in fact attended with a pronounced increase in the output of ammonia in the urine. The existence of the suspected acidosis would therefore seem to be established. It by no means follows that this is of itself sufficient to account for all the characteristic symptoms of methyl alcohol intoxication. Król noted that the amount of formic acid actually excreted by his experimental animals was too small to account for all of the ammonia simultaneously present in the urine. Other acids must also arise. In any event, however, the now clearly demonstrated acidosis is a factor which deserves to be taken into account in a consideration of the phenomena of poisoning with wood alcohol.

Medical News

DISTRICT OF COLUMBIA

New Officers.—Washington Obstetrical and Gynecological Society, October 10: president, Dr. J. F. Moran; secretary, Dr. Truman Abbe.

Hospital Building Dedicated.—The Woman's Missionary Society of the Methodist Episcopal Church, in session in Washington, October 19, dedicated Robinson Hall, a structure erected at a cost of $150,000, and dedicated by the society to Sibley Hospital.

Physician Invents Aeroplane.—Dr. Henry L. E. Johnson, Washington, has obtained a patent on a constructive principle of an inverted arch for an aeroplane, which is designed to add to the safety of the machine particularly in descent, and to lower the center of gravity.

Woman's Clinic Opened.—A woman's clinic with the object of preventing as well as curing disease, has been opened at 716 Thirteenth Street, Washington. The clinic is open from 5 to 7 p. m., and two days in the week are devoted to children. The chairman of the medical committee is Dr. Elnora Folkmar.

ILLINOIS

Child Welfare Exhibition in Peoria.—Peoria is to have a child welfare exhibition in its coliseum from October 27 to November 4. Dr. Clifford U. Collins is chairman of the executive committee.

New Officers.—Tazewell County Medical Society at Pekin, October 14: president, Dr. G. W. Foekler, and secretary-treasurer, Dr. E. F. Kelchner, both of Delavan.——McDonough County Medical Society at Bushnell, October 7: president, Dr. W. W. Hendricks, Bardolph: secretary-treasurer, Dr. C. J. Rider, Bushnell.

Correction.—The secretary of the Illinois State Association for the Prevention of Tuberculosis requests that a correction be made in the news item in THE JOURNAL of October 14, in which it was announced that Dr. William A. Evans was elected president of the association. Dr. Evans withdrew his name from nomination, and Dr. George T. Palmer, Springfield, Ill., was elected president.

Illinois Conference of Charities.—The Illinois Conference of Charities held its annual meeting in Rockford, and elected the following physicians as officers and committeemen: first vice-president, Dr. George T. Palmer, Springfield; committee of service, Drs. George T. Palmer, Springfield, and John Bartlett, Galesburg; eugenics, Drs. William L. Healy, Anna Dwyer and Charles P. Caldwell, Chicago; W. H. C. Smith, Godfrey, and Edith B. Lowry, Chicago; medical social work, Drs. Adam Szwajkart, Chicago, and A. J. Brislen, Chicago; committee on exhibits and publicity, Dr. H. A. Pattison, Rockford.

Personal.—Dr. H. N. Bascom, Peoria, chief surgeon of the McKinley system, entertained the surgeons of the McKinley system at dinner at the Creve Coeur Club, October 15.——Dr. J. M. Kaiser, Somonauk, is confined to his home by reason of a cerebral hemorrhage——Dr. C. A. Wilcox, Amboy, is making satisfactory recovery from his recent operation in the Dixon Hospital.——Work has been commenced on a new solarium for Dr. P. E. N. Greeley, Waterman. The solarium will have twelve sun or outdoor sleeping-rooms.——Dr. E. P. Hatheway, Ottawa, is ill in the hospital with an infected wound of the arm.——Dr. J. Mather Pfeiffenberger, Alton, has returned from Europe.

Chicago

Personal.—Dr. Eugene S. Talbot and daughter, Dr. and Mrs. Herman L. Kretschmer and Dr. B. Barker Beason have returned from abroad.

Dinner to Interns.—The Chicago Medical Woman's Club gave its annual dinner to the woman interns in Chicago hospitals, October 18. Dr. Frank Billings was the guest of honor.

Special Meeting of Gynecological Society.—The Chicago Gynecological Society announces a special meeting to be held November 15, in the Florentine Room of the Congress Hotel. At this meeting Professors Krönig and Gauss will be the guests of honor, and papers will be read by Drs. Robert L. Dickinson, Brooklyn, and Thomas S. Cullen, Baltimore.

Hospital News.—The new West Side Hospital building at Lincoln and Harrison Streets was formally opened October 17. The building has cost $200,000, and has accommodation for 170 patients.——A five-story building, to cost about $100,000, is being erected at Washington Boulevard and North Campbell Avenue by the Washington Boulevard Hospital Association, which at present maintains the Monroe Street Hospital.

Recommendations Regarding Criminal Puinishment.—At the meeting of the Chicago Medical Society, October 14, the committee on criminal punishment made the following recommendations, and the report was adopted by the society:

> "The separation at all times of misdemeanants and felons.
>
> "That every aid be given the state's attorney's office and the judges to hasten grand jury hearings and final trials.
>
> "That every effort be made to encourage the extension of the reformatory idea to criminals of every class, excepting the incorrigible habitual criminal and those guilty of capital crimes, and that these latter be sentenced to 'state schools,' rather than to 'state prison.'
>
> "That a sentencing board or commission be appointed by the governor for the three state districts, to consist of seven members, who shall classify all criminals in the state, their family, physical, mental, and criminal history.
>
> "To encourage the women of Illinois to take better care and extend moral and material support to the women who have served sentences in penal institutions of the state, and thus preserve them from a life of vice or crime."

INDIANA

Sanitarium Incorporated.—The Dr. Stackhouse Sanitarium, Crawfordsville, has been incorporated with a capital stock of $20,000.

Hospital Contract Awarded.—The building committee of the Methodist Hospital, Indianapolis, have awarded a contract for the new pavilion, which will cost about $50,000 and will increase the capacity of the hospital to 285 beds.

Physicians Win Law Suit.—In the case of David Linn, Nappanee, versus Drs. Price and Price, Nappanee, in which $10,000 damages was claimed on account of alleged malpractice, a jury in the Superior Court at Elkhart, October 4, decided in favor of the defendants.

Antituberculosis Society Secretaries Organize.—An organization was perfected in Indianapolis, October 17, by secretaries of city and county antituberculosis societies of the state. W. B. Thurber, Indianapolis, was elected president; Dr. C. W. Hartloff, Evansville, vice-president, and Mrs. E. B. Keaher, Anderson, secretary-treasurer.

Tri-State Association of Colored Physicians.—At the fifth annual session of the Indiana Association of Negro Physicians, held in Indianapolis, October 15 and 16, under the presidency of Dr. A. H. Wilson, Indianapolis, a resolution was adopted that the association combine with like associations of Ohio and Kentucky to form a tri-state organization.

Trachoma Hospital Desired for Bartholomew County.—The State Board of Health has requested that a special hospital be established in Bartholomew County for the treatment of trachoma. In a recent inspection made by Dr. James A. Nydeggar, U.S.P.H.S., of the children in the public schools in Bartholomew County, forty-eight cases of trachoma were discovered.

District Society Meeting.—The thirteenth annual meeting of the Eleventh Councilor District Society was held in Peru, October 16, and the following officers were elected: president, Dr. G. R. Daniels, Marion; vice-presidents, Drs. J. M. Toney, Vanburen; W. A. Domer, Wabash; Claude S. Black, Huntington; P. B. Carter, Macy; G. R. Coffin, Monticello, and C. C. Hickman, Yeoman.

Personal.—Dr. William F. Smith, Vincennes, is reported to be seriously ill.——Dr. Amzi Weaver, Elizabeth, fractured his arm recently while cranking his automobile.——Dr. Henry Jameson, formerly dean of the Indiana Medical College, has been elected president of the Indianapolis Street Railway Company.——Dr. John J. Briggs, Indianapolis, who has been ill with typhoid fever, is reported to be improving.——Dr. Charles R. Crow, Indianapolis, is reported to be seriously ill with neuritis.

Health Board Lacks Funds.—The Board of Health of Indianapolis is in serious difficulty on account of lack of funds. Under a recent law the board fixed the salaries of all its employees. A member of the City Council, having been treated at the City Hospital, introduced a resolution increasing the pay of student nurses in that institution. This resolution was adopted, but the city attorney held that it was illegal, and as the board thought it inadvisable to increase the pay of nurses, the council has held up the appropriation for the Board of Health and has refused to pay expenses incurred during the recent flood. The contagious disease fund having been exhausted on account of large increase in cases of diphtheria, the Board of Health is in a bad financial condition.

MARYLAND

Baltimore

Sanitarium Burned.—The Edgewood Sanitarium was partly destroyed by fire early on the morning of October 14. The dense smoke caused the death of two patients by suffocation. There were ten patients in the institution at the time of the fire. A nurse was severely burned and received other injuries in attempting to rescue the patients who were suffocated.

Dinner to Students.—Dr. Howard A. Kelly gave a dinner to 500 medical students from the various medical colleges in Baltimore on October 17. Governor Goldsborough and prominent clergymen who are interested in the welfare of the many medical students who come to Baltimore each year, delivered addresses.

Semi-Annual Meeting of the Faculty.—The semi-annual meeting of the Medical and Chirurgical Faculty of Maryland was held in Hagerstown, October 21 and 22. Dr. Carroll Fox, surgeon, U. S. Public Health Service, made a report on the milk supply in Maryland. A reception was tendered the members by Dr. J. McPherson Scott.

Brady Urological Clinic.—The first step toward the utilization of James Buchanan Brady's gift of $250,000 to Johns Hopkins Hospital for a special urological clinic, under the direction of Dr. Hugh H. Young, has been taken, when the contracts for the construction of the building were awarded. The building will be three stories in height, with a roof garden for convalescent patients. It is expected that the clinic will be completed and ready for the reception of patients in about one year. Mr. Brady's gift provides for an annual gift of $15,000 for maintenance and it is said that he has made substantial provision in his will for the continuance of the work of the clinic.

MICHIGAN

New Officers.—Ottawa County Medical Association at Holland, October 14: president, Dr. A. Brower, Drenthe; secretary-treasurer, Dr. H. J. Poppen, Holland.——Tri-County Medical Society (Lapeer, McComb and St. Clair counties), organized at Richmond: president, Dr. Robert M. Greenshields, Romeo, and secretary, Dr. R. J. Pelton, Armada.

State Board Election.—At the annual meeting of the state board of registration in medicine, held in Lansing, October 15, Dr. G. L. LeFevre, Muskegon, was elected president. Dr. Beverly D. Harison will continue to act as secretary of the board, as after eighty-seven ballots his opponent, Dr. Bret Nottingham, Lansing, had failed to receive the seven votes necessary for his election.

Hospital News.—Three units of the Detroit General Hospital, erected at a cost of about $500,000, are almost completed. These are the service building, the laboratory and the surgical building. Two additional buildings, a children's building and a maternity building, are now in sight.——The superintendent of Grace Hospital, Detroit, has been authorized to proceed with the construction of a new service building to cost $40,000.——The cornerstone of the new St. Joseph's Sanitarium, Ann Arbor, was laid September 21.

Personal.—Dr. R. T. Mason, Detroit, dislocated his right shoulder in a collision between his motor car and another machine recently.——Dr. L. W. Toles has been elected president and Dr. J. Earl McIntyre secretary of the board of control of the Ingham Sanitarium, Lansing.——Dr. S. N. Insley, Grayling, fractured his arm while cranking his automobile, recently.——Dr. Hattie G. Schwendener, St. Joseph, was struck by an interurban car, recently, and seriously injured.——Dr. Jennie Crozier, Grand Rapids, has gone to England, where, after three months' study of tropical medicine, she will return to her post of duty in India.——Dr. C. C. Clancy, Port Huron, has been elected president of the medical section of the National Fraternal Congress.

NEW JERSEY

Memorial Hospital Opened.—The Stumpf Memorial Hospital, Kearny, was formally opened, October 1, and received its first patients October 3.

Personal.—Dr. L. M. Halsey, Williamstown, who has been seriously ill, is reported to be improving.——Dr. Chauncey V. Everitt has resigned from the medical staff of the Jersey City Hospital.——Drs. Edgar A. Ill, Richard Coe and William D. Miningham, all of Newark, have been appointed members of the consulting staff of the Overbrook Insane Hospital.——Dr. E. J. McConaghy, Camden, was seriously injured in an automobile accident, recently.——Dr. Phillip E. Krichbaum, Montclair, fell while entering his automobile recently, fracturing his right arm.

New Officers.—Medical Society of Cape May, at Cape May Court House, October 7: president, Dr. Clarence W. Way, and secretary, Dr. Eugene Way, both of Dennisville.——Morris County Medical Association at the State Hospital, Greystone Park: president, Dr. James B. Griswold, Morristown; secretary, Dr. Henry W. Kice, Wharton.

Experts Formulate Plans for Care of Feeble-Minded.—A conference of experts was held October 10, at the State Institute for Feeble-Minded Women, Vineland, to formulate sane and economical plans for the care of the feeble-minded, and to interest alienists and psychologists in their training as well as in the diagnosis of their cases. Dr. Madelein Hallowell, superintendent of the institution, outlined an economical, human and safe system, by the gathering by the state of all its mental defectives into large institutions conducted on the unit plan, where women and children can mingle and lead some semblance of a normal life, the men being in the same institutions in separate buildings.

NEW YORK

Hospital Fund Campaign Closes.—The eight-day campaign to raise $200,000 for St. Mary's Hospital, Niagara Falls, closed October 9, with a total subscription of $62,805.

Society Reorganized.—Fifteen practitioners of Essex County met at Port Henry recently and reorganized the Essex County Medical Society, electing the following officers: president, Dr. L. G. Barton, Willsboro; vice-president, Dr. C. B. Warner, Port Henry; secretary, Dr. Charles Payne, Westport, and treasurer, Dr. W. T. Sherman, Crown Point.

Instruments Donated to Hospital.—The collection of surgical instruments of the late Dr. Nathan Jacobson of Syracuse has been presented by his widow to St. Joseph's Hospital. Mrs. Jacobson also announced her intention of presenting the library of Dr. Jacobson, consisting of nearly 2,000 volumes, to the library of the College of Medicine of Syracuse University.

New Officers.—Wyoming County Medical Society at Warsaw, October 14: president, Dr. W. J. French, Pike; secretary-treasurer, Dr. L. H. Humphrey, Silver Spring.——Orleans County Medical Association at Medina, October 7: president, Dr. R. W. Bamber, Carleton; secretary-treasurer, Dr. J. F. Eckerson, Shelby.——Genesee County Medical Society at Batavia, October 9: president, Dr. J. B. Miller, Alexander; secretary, Dr. Sophy E. Page, Bethany.——Seneca County Medical Society at Interlaken, October 9: president, Dr. L. A. Gould, Interlaken; secretary, Dr. F. W. Lester, Seneca Falls.——Wayne County Medical Society at Palmyra: president, Dr. E. A. Nevin, Newark; secretary-treasurer, Dr. M. A. Veeder, Lyons.

Renew Tuberculosis Fight.—Joseph H. Choate, president of the State Charities Aid Society, in a recent letter to the members of that organization, urges an energetic campaign for the suppression of tuberculosis. While he sees ground for great satisfaction in the results already achieved, he believes that the number of hospitals for tuberculous patients should be further increased. The number of local hospitals for the treatment of tuberculosis has increased in the last six years from two to nineteen. There are now seventy-nine public health nurses where formerly there were only two. Free tuberculosis dispensaries have increased from two to twenty-six, and the anti-tuberculosis societies have increased from two to 300, the membership of these societies now numbering 10,000. There were in the state, outside of New York City, 3,350 deaths from tuberculosis during the first seven months of 1911; for the same period of 1912 there were 3,301, a decrease of 49. For the first seven months of 1913 there were 3,118 deaths, showing a further decrease of 183. Ten counties in the state have voted to establish tuberculosis hospitals but have not yet done so. These counties should be urged with all possible force to carry out their plans.

New York City

Harvey Society Lecture.—The third Harvey Society lecture will be given at the New York Academy of Medicine November 1, by Dr. Charles V. Chapin, Providence, on "The Air as a Vehicle of Infection."

Hospital Wing Dedicated.—The new wing of the Misericorde Hospital was formally dedicated by Cardinal Farley on October 12. The hospital now contains twenty-five private rooms, five semi-private wards, three large maternity wards containing 150 beds and a children's ward with a capacity of 125 cribs.

The Coming Safety Exhibit.—The American Museum of Safety plans to have an International Exposition of Safety and Sanitation at the Grand Central Palace, December 11 to 20. Several European governments are in communication with Director William H. Tolman of the American Museum of Safety with a view to displaying factory safety devices, novel playgrounds and various methods of preventing human waste. The Swiss government has promised to send a full line of exhibits.

Central Federated Union and Medical Inspection in the Public Schools.—At a recent meeting of the Central Federated Union, resolutions were passed by the Executive Committee and forwarded to the Board of Aldermen and to the Board of Estimate and Apportionment asking those bodies to favor the increased appropriation asked for by the Division of Child Hygiene of the Department of Health. The resolutions urged free medical inspection for all students in the public schools. In framing these resolutions the Central Federated Union was joined by a number of other fraternal, labor and benevolent organizations.

Oppose Building of Another Bronx Hospital.—At a hearing before the State Board of Charities on October 16 representatives of the Lebanon Hospital, which is located in the Bronx, opposed the plan of building a maternity hospital in that borough. The organizers of the Bronx Maternity Hospital claim that they have $30,000 pledged toward such an institution and believe that it is needed, while officials of the Lebanon Hospital think they are abundantly able to care for all the work in that vicinity and fear that another hospital would divide the support and weaken them and at the same time would add to the burden of the city.

NORTH CAROLINA

Personal.—Dr. R. H. Lewis, Raleigh, who has been ill at his home in the country, is reported to be improving slowly.——Dr. Albert Anderson, Raleigh, has resigned as a member of the Wake County Board of Education.

State to Furnish Antityphoid Vaccine.—Dr. C. A. Shore, director of the state laboratory of hygiene at Raleigh, announces that he is now able to furnish antityphoid vaccination at cost, in accordance with the action of the last state legislature.

Pellagra Building.—Mr. George W. Watts, Durham, will add a new building to the Watts Hospital in that city, to be devoted exclusively to the study and treatment of pellagra. A proposition has recently been made to the general government to establish a pellagra station in Durham, with headquarters in the Watts Hospital.

PENNSYLVANIA

White Haven Open to All Physicians.—By a recent action of the board of directors of the White Haven Sanatorium Association, it was decided that applications for admission to the sanatorium would be received from any physician in good standing, and not from members of the regular examining staff alone, as heretofore.

Personal.—Dr. W. W. Livingston, Dunlo, suffered a fracture of the base of the skull and spinal injuries, by the overturning of his automobile, October 10.——Dr. E. R. Walters, who recently resigned as a director of public health of Pittsburgh, was given a farewell dinner by the employees of the public health and charities department, October 14. Dr. H. B. Burns, the new director of public health, officiated as toastmaster.

Philadelphia

New Children's Hospital.—The managers of the Children's Hospital have purchased a site at Eighteenth and Bainbridge Streets, where they will erect a group of modern hospital buildings, which will have the best modern facilities and equipment for the care of sick children, for research and education, and for the prevention of children's diseases.

Personal.—Dr. John Grier Hibben, president of Princeton University, was the guest of honor of the medical club of Philadelphia, October 17. Dr. Hibben addressed the physicians and pointed to their opportunity in combatting the social diseases.——Dr. H. Augustus Wilson has resigned as visiting orthopedic surgeon to the Philadelphia general hospital.——Dr. William G. Stimson, chief physician of the Naval hospital in this city, has been ordered to Washington, D. C., as a member of the board of examiners of the Marine Hospital Service.

RHODE ISLAND

Hospital Opened.—The Blackstone Hospital, Pawtucket, was formally opened and dedicated September 22. The institution can accommodate sixty-five patients and is provided with thoroughly modern equipment.

Typhoid Epidemic in Artillery Company.—A number of the members of the Newport Artillery Company are reported to be ill with typhoid fever in the Newport Hospital, the cause being said to be a result of the trip of the organization to Put-In-Bay, Ohio, to take part in the Perry Centennial celebration.

TENNESSEE

Witherspoon Club.—A social club, named in honor of Dean John A. Witherspoon of Vanderbilt University, was organized by the members of the senior class of the Vanderbilt Medical School, September 29, with an initial membership of twenty-one.

Sanatorium Operated by Labor Union.—The Pressmen and Assistants' Union has recently completed a sanatorium for consumptives at Rogersville, Tenn., where members of the craft suffering from tuberculosis may receive care at the expense of the local union.

New Medical Society Formed.—The physicians of Cocke County met at Newport recently and organized the Cocke County Medical Society, electing the following officers: president, Dr. A. J. Nease; vice-president, Dr. C. T. Burnett, and secretary-treasurer, Dr. David Seay.

Term Lengthened at Vanderbilt.—With the opening of the medical department of Vanderbilt University, Tennessee, this year, the term of the medical school will be lengthened to nine months corresponding with the dates of the academy and engineering departments. This change is in line with the expansion of the medical department under the Carnegie endowment.

Personal.—Dr. J. B. Steele, city physician of Chattanooga, has been appointed chief of staff of the Erlanger Hospital.——Dr. John Allen Gentry, Chattanooga, has been appointed chief surgeon of the Southern Bell and Cumberland Telephone and Telegraph Companies, with headquarters in Atlanta, Ga.——Dr. F. M. Acree, Dover, was thrown out of his buggy, September 24, and seriously injured.——Dr. John A. Witherspoon, Nashville, has returned from abroad.——Dr. Thomas M. Smoot has resigned as mayor of Woodbury.——Dr. S. Burchart, Memphis, has gone abroad for the winter.

GENERAL

Correction.—The illustrations accompanying the article by Dr. H. D. Chapin in The Journal last week, pages 1419-22, were printed in a turned position. The correct position can be seen by holding The Journal sideways with the top of it on the right hand. The illustrations will appear in the correct form in the author's reprints, a copy of which we will send on receipt of a self-addressed stamped envelope.

Bequests and Donations.—The following bequests and donations have recently been announced:

St. Luke's German and Lincoln Hospitals, New York City, and the New York Eye and Ear Infirmary, $25,000 each.

Mount Sinai Hospital, New York City, $100,000, by the will of Benjamin Altman.

The Greenport Hospital, Long Island, $1,000, by the will of Salem D. Goldsmith.

For the St. Joseph's Hospital, Yonkers, N. Y., by popular subscription, $63,246.

Children's Hospital, Boston, Mass., $20,000 by the will of Miss Harriet O. Cruft.

Railway Surgeons Elect Officers.—At the tenth annual meeting of the American Association of Railway Surgeons, held in Chicago, October 15 and 17, the following officers were elected: president, Dr. D. S. Fairchild, Clinton, Iowa; vice-presidents, Drs. E. S. Judd, Rochester, Minn., R. A. Douglas, Collinsville, Okla., and L. L. Parsons, Brookhaven, Miss.; secretary-editor, Dr. L. J. Mitchell, Chicago (reelected); treasurer, Dr. H. B. Jennings, Council Bluffs, Iowa, and members of the executive board, Drs. S. C. Plummer, Chicago, and D. Y. Roberts, Louisville.

Students of Criminology Organize. — Preliminary steps toward the formation of a national association of psychologists, sociologists and medical scientists for scientific research addressed to fundamental conditions underlying criminology were taken at a dinner given by Dr. David C. Payton, superintendent of the Indiana Reformatory, Jeffersonville, at Indianapolis, October 13, at which thirty experts in criminology were present. A committee consisting of Dr. Peyton and

Prof. R. B. Von Klein Smid, Jeffersonville, Ind., Lightner Witmer, Philadelphia, Dr. William Healy, Chicago, and H. H. Hart of the Russell Sage Foundation, New York City, was appointed to work out plans for the new national organization.

Pediatrists Invited.—Through the courtesy of the New England Pediatric Society, an invitation has been extended to the members of the pediatric section of the Medical Society of the State of New York to attend the joint meeting of the New England, Philadelphia and New Jersey Pediatric societies, and the Pediatric Section of the New York Academy of Medicine, being held in Boston, November 8. The morning and afternoon are to be devoted to visiting hospitals, including the new Children's Hospital and the new Infants' Hospital, and clinics will probably be given at the Massachusetts Babies' Hospital, the Massachusetts General Hospital and the Boston Dispensary. There will be a dinner in the evening, and following this a scientific session at which four papers on pediatric subjects will be read and discussed.

Technology Faculty Member Goes to Public Health Service.—Prof. Earle P. Phillips, well known as a consulting sanitary engineer and as a contributor to the various technical journals along the lines of sanitary chemistry, bacteriology and engineering, has resigned from the faculty of the Massachusetts Institute of Technology, Boston, and from the staff of the sanitary research laboratory in that institution, to accept the professorship of chemistry in the United States Hygiene Laboratory, conducted by the United States Public Health Service in Washington, succeeding in that position Professor Franklin. Professor Phillips' work at the Hygiene Laboratory will be largely a continuation of his previous activities and will be devoted especially to investigation of the pollution of interstate streams—a work recently undertaken by the Public Health Service.

Sale of Christmas Seals by National Tuberculosis Association.—The Christmas seals of the National Association for the Study and Prevention of Tuberculosis have become familiar to almost everyone. In 1912 over forty million seals were sold, the proceeds of which were devoted to this most worthy cause. For 1913 the seal which we reproduce has been accepted; it is significant of the holiday season and is worthy of a place on every Christmas package or letter. It is proposed to distribute one hundred million of the seals, and it is hoped that by the 25th of December not one will remain unsold. The project is one which has previously been well supported by medical men; a renewed and greater interest should be given.

Dr. Reid Hunt's Successor.—An announcement of great importance is the appointment of Prof. Carl Voegtlin as professor of pharmacology in the Hygienic Laboratory, United States Public Health Service, to succeed Prof. Reid Hunt, now head of the department of [illegible] at Harvard University. Professor Voegtlin was [illegible] in 1879, received his degree of Ph.D. at Freiberg, Germany, in 1902 and then did postgraduate work at Victoria University, Manchester, England, in 1903. In 1904 he accepted the position of instructor in chemistry in the University of Wisconsin and one year later became assistant in medicine at Johns Hopkins University, rising successively to associate and associate professor of pharmacology. Since that time he has studied on various occasions at the universities of Berlin and of Munich. His work covers researches in pathologic protein metabolism, treatment of tetany with calcium salts, function of the liver in anaphylaxis and jaundice, the function of the adrenal cortex, pharmacology of digitalis and nitrates and the treatment of experimental beriberi. He is a member of a number of important scientific organizations, among them being the Society of Pharmacology and Experimental Therapeutics, American Medical Association, Society of Biological Chemists, and the American Physiological Society. Needless to say, the Hygienic Laboratory is to be congratulated on securing the services of a man of such high qualifications as Professor Voegtlin to succeed Professor Hunt. His appointment assures a continuance of the high standard of research work in pharmacology conducted at the Hygienic Laboratory. He is a young man of exceptional capacity and scientific attainments and with still greater promise for the future. Dr. Reid Hunt, whose appointment to the professorship of pharmacology at Harvard University has been coincidentally announced, is the second member of the Council on Pharmacy and Chemistry to go to Harvard.

CANADA

Increase of Defectives in Canada.—The following statistics of the bulletin just issued at Ottawa gives the defective classes in Canada: Blind, 3,238; deaf and dumb, 4,584; insane, 14,702; idiotic, 5,387, making a total of 28,611, of whom 15,530 are males and 13,081 females. From 1901 to 1911 the population increased 34.17 per cent. and the defectives increased 9.42 per cent. The only province which did not exhibit an increase was New Brunswick.

Personals.—Dr. Orr has been appointed medical officer of health at Medicine Hat, Sask.——Dr. H. J. R. Lindsay has been appointed medical officer of health at Yorkton, Sask.——Dr. James C. Fyshe, for the past two years medical superintendent of the Montreal General Hospital, has been appointed superintendent of the Edmonton, Alberta, hospitals.——Dr. G. Arthur Winters, Toronto, will spend two years abroad in graduate study.——Dr. J. T. Fotheringham, Toronto, has been appointed chief of one of the medical services in the Toronto General Hospital, succeeding Dr. W. P. Caven, resigned.

Pollution of Boundary Waters.—Dr. J. W. S. McCullough, chief health officer for Ontario, has left for Washington, D. C., to lay before the International Waterways Commission the report on the pollution of boundary waters based on investigations carried on during the past summer. Dr. McCullough will be joined in Washington by Dr. McLaughlin, who had charge of the work on the American side. The contention of the health authorities is that water contamination exists where the raw sewage of large cities is allowed to run into lakes and rivers, and this extends to such distances as to prove a serious menace to other places depending on these streams for a domestic supply of water.

Hospital News.—The Dominion Steel Corporation will build a hospital at Waterford, N. S. It will be administered by a board of trustees, one-half appointed by the company and one-half by the citizens of Waterford.——London, Ont., has recently added twelve new private wards to the Victoria Hospital.——By the end of the present year the new wing of the Kingston General Hospital will be ready for occupation.——The Brant Sanatorium for Consumptives has been opened near Brantford, Ont. The building cost $23,000 and has accomodation for twelve patients.——The Hamilton (Ont.) General Hospital will be improved to the extent of $100,000.——A new hospital for babies is being erected in Montreal.——The hospital at Selkirk, Man., is to be enlarged at a cost of $65,000.——The provincial university of Saskatchewan at Saskatoon has prepared plans for a new hospital.——A new isolation hospital is to be erected in Regina, Sask., at a cost of $77,600.——The Dominion Government has granted 320 acres of land on the main line of the Canadian Pacific Railway in Alberta for a sanatorium for incipient cases of tuberculosis.

LONDON LETTER

(*From Our Regular Correspondent*)

London, Oct. 11, 1913.

The National Insurance Act

A curious situation has occurred in connection with medical benefit under the insurance act. For one reason or another, 400,000 of the insured in London (about a quarter of the whole) have not selected any physician on the panel. In some cases the reason is a rooted objection to the act or an objection to being treated by any one but the patient's own physician, who has not joined the panel. In other cases the persons have not been ill, do not expect to be ill, and will not go to the trouble of selecting a physician. The result is that a large sum, $525,000, has accumulated in the hands of the insurance committee. The question has arisen, To whom does this belong? On the one side it is argued that the money belongs to the physicians on the panel because it is already set aside for medical service and they had taken the risk of the illness of these persons on an insurance basis. On the other hand, the insurance committee has taken a lawyer's opinion, which is to the effect that the physicians on the panel are entitled to a definite sum calculated at so much per head for the insured persons on their list and to no more.

A case has occurred in which for the first time the question has been raised as to the responsibility of a panel doctor to pay for the medical attendance of an insured person on his list whom he failed to attend when called. The patient was attacked with pneumonia. A message was sent to the physician asking him to call. As he did not come another message was sent four hours later and he promised to come. A third message was sent three hours later by the patient's sisters and some altercation took place. The physician complained that he had not been summoned in the morning when he could have paid the visit on his rounds. He was told that if he would not come now some one else would be called. He said, "I am not coming; go and get some one else." For the defense the doctor stated that the first message reached him at 3 in the afternoon when he had a "snack" and attended patients in his office. He was leaving to attend the patient when the latter's sisters arrived and insisted on his going immediately. He became nettled at their manner and when they said that they would get another physician he took that as his dismissal. Judgment was given for $11 claimed by the plaintiff for the expense of engaging another physician, but leave was given to appeal on a point of law.

Sir William Osler on Medical Examinations

At the opening of St. George's Hospital Medical School, Sir William Osler delivered an address on examinations. He said that the great difficulty in medical study was the growth of every subject of the curriculum. An educational system framed for simple tests and simpler conditions had been outrun, and the pressure at the present day was hard on the teacher but harder on the student. From their medical workshops they turned out after five years' preparation the finished material, nearly one-half of which was declared to be defective and rejected. The growth of rejection in the final examination was demonstrated by the following figures: In 1861, 12 per cent.; in 1876, 2 per cent.; in 1886, 32 per cent., and in 1895, 41 per cent. He made the following suggestions: Simplify the curriculum so as to give the student more time. Allow the teachers a free hand in the matter of systematic lectures. Let the lectures be reduced to a minimum, or abolished altogether. The subject of medicine may be taught, for example, without systematic lectures. The lecture has its value, but its day is gone, and it should give place to other methods better fitted to modern conditions. They should boldly acknowledge the futility of attempting to teach all to all students. They should burn the anatomic fetish to which they had sacrificed long enough and to their great detriment. "Glance at Cunningham's 'Anatomy.' It has 1,465 pages, many in small type, and not one without a water-jump for the first grand national of the medical student. It is barbaric cruelty with so much ahead to burden the mind with minutiae which have only a Chinese value—a titanic test of memory." He would give credit for work done throughout the course. Let all who taught examine, and let education and examination go hand in hand. Further, he would simplify the examinations. Let them cut out the written papers, for as a student handled a patient it was easy to tell whether or not he had had a proper training, and for that purpose fifteen minutes at a bedside were worth three hours at the desk. When possible, the evidence of original work should be substituted for examination. He would compel no student to pass an examination in the same subject a second time.

The Dangers of Radium

Last week reference was made to the fact that most of the staff of the Radium Institute were suffering from burns produced by radium. The assistant medical superintendent, Dr. Arthur Burrows, states that most of the staff have been burned to a greater or less extent at some time or another. In his own case he found the skin peeling off his fingers when he went to play golf. The nurses, however, who do most of the actual handling, suffer most. In addition to the more or less painless skin-peeling, the finger-nails become brittle and split down the center, ulcerated spots appear, and in time the hands become totally anesthetic. It is curious that the hands of those who have much to do with radium are always far more susceptible to heat than to cold. Gloves are not much protection. The only thing to do when the fingers show these symptoms is to have nothing to do with radium until they recover. Those who develop burns are usually given some work in connection with the institute which does not involve immediate contact with the element. Radium in course of time burns most things to which it comes in contact. For instance, the lining of the boxes in which it is kept is often entirely eaten away. The ill effects are not felt in the human body until a fortnight after the contact. It eats away the abnormal tissues, such as carcinoma, sarcoma, etc., and leaves the surrounding normal tissues in an ordinary condition. In its antipathy to abnormal tissues lies its curative properties in these cases. But in time, or as the result of excessive application, radium will have an effect also on the normal tissues. A subsidiary effect on the patient is increased susceptibility to changes of temperature over areas that have been treated with radium. Many patients who have had rodent ulcers and superficial skin lesions cured with radium experience great discomfort at the site of the old lesion when very cold or very warm air plays on it. This susceptibility, however, gradually disappears in two or three months. A marked condition of lethargy is frequently, it might almost be said invariably, noted in patients receiving prolonged exposures with large quantities of heavily screened radium. It generally makes its appearance about the fourth day of the treatment, and passes off within a few days of the cessation of the exposures.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Oct. 10, 1913.

Mosquitoes in Paris

Continuous rains this summer and autumn have favored the breeding of mosquitoes, which swarm at present in various quarters of Paris. Professor Laveran, on account of his well-known mastery of the subject, was requested by the Council on Public Hygiene to study the subject, and has recommended measures of public education with regard to the prevention of mosquito-breeding.

Physical Culture in the Schools

Professor Gilbert has called the attention of the minister of public instruction to the failure to put into force the law of February, 1880, which makes gymnastic exercises obligatory in lyceums, colleges and primary schools. It was decided that the first application of the law should be made at the Janson-de-Sailly Lyceum. Only those students are to be excused who can produce a medical certificate that their health will not permit them to join in the exercise. It is to be hoped that the measure will soon be extended to all the schools to which the law applies.

Unveiling of a Monument to the Memory of Professor Raymond

I have already mentioned the unveiling of a bronze medallion in memory of the late Professor Raymond at the Salpêtrière (The Journal, Aug. 9, 1913, p. 422). On October 4 a bronze bust of Professor Raymond was unveiled at his birthplace, Saint-Christophe, near Tours.

Education of a Child Relieved of Congenital Blindness

Dr. Moreau of Saint-Etienne reports in the *Loire médicale* the history of a child of 8, born blind, who was operated on in his service for a complete bilateral cataract. Until entering the hospital, the child had lived at home with his father, a poor peasant, and had received no education whatever. It was an anxious moment when, a week after the operation, the bandage was removed from the eyes. But the child, on being able to see for the first time, made simply a few meaningless sounds. The bandage was replaced, and the trial repeated two days later. The child again showed no emotion. As each object was shown to him after he had touched it so that he knew it perfectly well, he said that he did not know what it was. It took many days for the child to acquire an idea of colors, but when he did, the color-concept assumed an abnormal significance, and everything was interpreted from this point of view. Whatever object was shown to the child was white or black according to whether it faced the light or was in shadow. He analyzed everything that he saw into colored spots. Each new thing that he learned, however, was of use in appreciating things that came after; thus, when the child learned that an object was a box, everything empty that he could stick his hand into was for him a box: his drinking-cup, his cap, his boots, etc. Whenever he wished to take hold of anything he acted as one does who can see, but in grasping it he relied more on the sense of touch than he did on sight. He had no sense of space. He tried to touch lamps which were a hundred feet away. He mistook the moon for one of the latter. He reached for the stars. Fifteen months after his entrance into the hospital he could not read, in spite of the efforts of the nun who took care of him to teach him the alphabet. Then his father took him away. Dr. Moreau saw the child a year later. He had remained at home without further education, had learned nothing new, and had forgotten most of what he had picked up while at the hospital.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Oct. 3, 1913.

Future Regulation of the Relation of Physicians to the Krankenkassen in Berlin

The president of the Berlin Insurance Bureau, the highest local authority for the social insurance law, has presented a draft of principles which are to form the basis for regulating the relations between the Krankenkassen and physicians. As these conditions will serve as a model for many Krankenkassen in the empire, and govern a great part of the entire practice of Berlin, the ultimate form of the regulations is of very special importance. The Krankenkassen are to have the right to determine the medical system that is suitable for the societies. In any society the physicians appointed form a medical league to be represented by a business board. The Krankenkassen have the right to appoint special confidential physicians *(Vertrauensärzte)*. In every society a commission on complaints is to be appointed, consisting of the same number of representatives of the society and of the society physicians. Societies which accept these rules will form (1) an election committee for the selection of the physicians to be appointed for the society, and (2) an arbitration court for the settlement of disputes. With reference to the appointment of insurance physicians the draft gives the following: The number and territory of physicians are to be determined by the directors of the society. According to the new apportionment of physicians, one physician to 800 members is to be regarded as normal. A registration bureau is to be established and from the list of suitable names the election bureau is to fill vacancies. Individual solicitation for appointment is forbidden on pain of exclusion from the eligible list. Contracts must be made in writing between the society and the physician to be appointed or the medical committee of the society. In the latter case, the other physicians become responsible for the performance of the duties of insurance physician with the signing of a reciprocal bond. Insurance physicians must not have separate offices for insurance work, must not treat patients in common as to time or place with charity patients, and must not use them for teaching purposes without their express permission. The insurance physician is to be assured sufficient rest on Sundays and holidays. For the remuneration of the insurance physician a definite annual fee of $1.25 (5 marks) per member is established. The work of the insurance physicians includes also night visits and obstetrics, including abortion. Night visits are to be paid for at the rate of $1.25 (5 marks) and obstetric attendance at $3.75 (15 marks) extra.

In the discussions of the central league of the Berlin insurance physicians over this draft of regulations, dissatisfaction with the marked tendency to restrict the rights of physicians in favor of the Krankenkassen was generally expressed. The first provision by which the Krankenkassen alone are to have the right to determine the medical system which is to be enforced is particularly objectionable, because with this right the free choice of physicians, the ideal to be sought for, which exists in a great number of the societies, can be abolished. Moreover, special opposition appeared to the provision that most physicians after the reorganization will be transferred from the society to which their previous patients belonged and will not be automatically reappointed, but must first secure a new election. The provision by which the insurance physicians' offices may not be located in a different place from their private offices was considered to be a serious damage to many specialists who, on account of the great distances in Berlin, are compelled to have offices for the insurance patients in another quarter of the city from that in which their private residences are located. The fee of $1.25 (5 marks) is regarded as too little. At least $1.37 (5.5 marks) was demanded.

New Sanitary Office of the Military Institute

The establishment of higher sanitary service in our army received a considerable extension, October 1, by the establishment of a new sanitary office for the Military Institute. The function of this bureau is the examination of all the military reports in accident cases, inspection of parade grounds, military schools, etc.

Marriages

William Ernest Balsinger, M.D., Houston, Tex., to Miss Loretta L. Brown of Fargo, N. Dak., at Houston, October 7.

Edward Brendon, M.D., Farley, New Hartford, Conn., to Miss Mary Elizabeth Shannon of Collinsville, September 30.

James Payton Leake, M.D., U. S. P. H. S., Washington, D. C., to Miss Mary Chase King of Baltimore, Md., October 4.

George Huston Bell, M.D., New York City, to Miss Florence Winifred Collings of Halifax, N. S., September 27.

Russell McWhorter Cunningham, M.D., Ensley, Ala., to Miss Annice Taylor of East Lake, Ala., October 4.

Albert Eugene Sterne, M.D., Indianapolis, to Mrs. Stella Gallup Pickrell of Evanston, Ill., October 18.

Alfred C. Girard, M.D., U. S. Army (ret.) Washington, D. C., to Miss Charlotte Epping, October 8.

Axel Emanuel Hedlund, M.D., Dalton, Neb., to Miss Ethel M. Kreader of Nebraska, September 21.

James L. Holden, M.D., Columbus, Ohio, to Miss Brenda Miller of Zanesville, Ohio, October 9.

Arthur Christian Slinde, M.D., to Miss Regina Alicia Murphy, both of Chicago, October 8.

William Spencer Needham, M.D., to Miss Mae McNeil, both of Louisville, Ky., August 23.

Walter G. Eisenman, M.D., Chisholm, Minn., to Miss Hinkle of Chicago, October 9.

Ida Rebecca Lantz, M.D., and Mr. Franklin Muir, both of Spokane, Wash, September 3.

Louis Northcott Markham, M.D., Longview, Tex., to Miss Princess Finch, October 22.

Oliver D. Walker, M.D., to Miss Margaret M. Moore, both of Salina, Kan., October 9.

Clarence J. Kenney, M.D., to Miss Eunice Thomsen, both of Milwaukee, October 9.

Deaths

William Hudson Wathen, M.D. one of the most prominent men in medicine south of the Ohio River; a gynecologist of wide repute; died in St. Anthony's Hospital, Louisville, October 7, aged 67. He was born near Lebanon, Ky., the son of Richard and Sophia Abell Wathen. He received his preliminary education in St. Mary's College, and took his medical course at the University of Louisville, graduating in 1870. He received from Notre Dame University the degree of LL.D. in 1895. He began practice in Louisville in 1871. He was one of the founders of the Kentucky School of Medicine, and served as its dean for several years, and as professor of abdominal surgery and gynecology on its faculty. After the consolidation of the school with the University of Louisville, he retained this chair in the new institution. He was a Fellow of the American Medical Association, chairman of the Section on Obstetrics and Gynecology in 1889, and orator in surgery in 1907. He was a member of the Kentucky State Medical Society, and its president in 1888; a fellow of the American Gynecological Society, and a charter member of the Louisville Clinical Society. He was also a member for many years of the Mississippi Valley Medical Association and many other learned societies. He took a deep interest in medical education, and was one of the leaders in its renaissance in Kentucky. After the enactment of the medical law Dr. Wathen served as medical referee for Jefferson County, and to him, more than to any one else, with one exception, is due the fact that Kentucky occupies the unique position of being the only state which has not in it an advertising or quack doctor. He did much original work in surgery, and ranked at the head of the specialists in his state, especially with reference to vaginal surgery. He was an indefatigable worker, a loyal friend and an honest but persistent fighter. In his death, which occurred after a three weeks' illness, the profession of Kentucky has lost probably its most effectual individual worker. At his funeral six of his nephews acted as active pallbearers. The staff of St. Anthony's Hospital, of which Dr. Wathen was the senior member, on October 9, unanimously adopted resolutions setting forth the honesty of purpose, indomitable courage of conviction and uniform kindly courtesy, his faithful service and unswerving attention to duty; extending sympathies and condolence to the bereaved family and to the sisters in charge of the hospital, and directing that a copy of the resolutions be spread on the minutes of the staff and hospital and duly published.

Charles Eugene Michel, M.D. Medical College of the State of South Carolina, Charleston; 1857; a surgeon in the Confederate service during the Civil War, division medical inspector at its close, and since that time an oculist of St. Louis; for many years professor of ophthalmology in the Missouri Medical College, and a member of the staff of the St. Louis Eye, Ear, Nose and Throat Infirmary; said to have been the first to employ electrolysis in his specialty, and to use the present accepted method for the removal of pterygium, and one of the first to discard the method of keeping cataract patients in a dark room for a long time after operation; died at his home in St. Louis, September 29, aged 80. The directors and staff of the infirmary of which he was so long a member of the active and honorary staffs adopted resolutions deploring Dr. Michel's death, and setting forth his services to the medical profession and especially to ophthalmology.

James Lewis Srodes, M.D. University of Pittsburgh, Pa., 1881; a Fellow of the American Medical Association and a member of the Association of Military Surgeons of the United States; surgeon of Pennsylvania Volunteers during the Spanish-American War; for one term a member of the House of Representatives of Pennsylvania, and for eleven years superintendent of the Allegheny County Home and Hospital for the Insane, Woodville, Pa.; died at his home in Woodville, September 26, aged 51.

Robert L. Brodie, M.D. Medical College of the State of South Carolina, Charleston, 1851; a Fellow of the American Medical Association; assistant surgeon in the United States Army from 1854 until the outbreak of the Civil War, when he resigned and entered the Confederate service, in which he served as medical director; afterward a resident of Charleston; at one time president of the Medical Society of South Carolina; died at his home in Charleston, October 2, aged 84.

Thomas Jacob Biggs, M.D. Medical College of Ohio, Cincinnati, 1887; formerly a Fellow of the American Medical Association; a member of the Connecticut State Medical Society; at one time health officer of Glendale, Ohio, and acting assistant surgeon, U. S. Army; for many years a practitioner of Stamford, Conn., and surgeon for the Stamford Hospital; died in the Somerset Hospital, Somerville, N. J., October 11, from chronic nephritis, aged 48.

Herman D. Peterson, M.D. Chicago Medical College, 1892; a Fellow of the American Medical Association; a member of the Physicians' Club of Chicago and Mississippi Valley Medical Association; anesthetist to St. Luke's Hospital, Chicago, and attending gynecologist to St. Luke's Hospital Free Dispensary; lecturer on anesthetics in Northwestern University Dental School; died October 18, while being taken to St. Luke's Hospital, from pneumonia, aged 43.

Jerome Leslie Stone, M.D. New York University, New York City, 1878; a member of the Minnesota State Medical Association; physician in charge of the Rochester (N. Y.) Sanatorium from 1880 to 1885, and since that time a practitioner of Minneapolis; was found dead in his home in that city, October 8, from the effects of poison believed to have been self-administered, aged 62.

Nathaniel Meacon Semple, M.D. Washington University, St. Louis, 1897; a Fellow of the American Medical Association, and a member of the St. Louis Ophthalmological Society; assistant in the eye clinic in his alma mater; consulting oculist to the United Railways Company of St. Louis and the Missouri Baptist Sanitarium; died at his home in St. Louis, October 3, aged 37.

Charles John Martin Willich, M.D. Bellevue Hospital Medical College, 1893; for thirty-two years a tester of scientific apparatus, and prominent as a physicist and chemist; died at his home in Brooklyn, September 23, from malignant disease of the throat, aged 62.

Frank Frazer Thomson, M.D. Jefferson Medical College, 1894; chief medical examiner of a Philadelphia insurance company and a member of the staff of the Presbyterian Hospital; died at his home in Philadelphia, September 21, from uremia, aged 45.

Mark E. Crawford, M.D. Missouri Medical College, St. Louis, 1881; a member of the Missouri State Medical Association; died at his home in Camden, July 31, from cerebral hemorrhage, aged 58.

Charles B. Tompkins, M.D. Rush Medical College, 1861; assistant surgeon and surgeon of the 17th Illinois Volunteer Infantry, and surgeon of the 59th Illinois Volunteer Infantry during the Civil War, afterward a practitioner of Lewistown, Ill.; since 1886 a practitioner of Jasper, Fla.; died at the home of his son in South Jacksonville, Fla., September 17, aged 75.

Robert Delos Smith, M.D. Jenner Medical College, Chicago, 1903; of Yerington, Nev.; a Fellow of the American Medical Association; one of the leading practitioners of Mason Valley, Nev., where he founded hospitals at Yerington and Mason, and was a surgeon for the mine smelter and local railroad surgeon; died suddenly in Denver, October 2, aged 41.

Herman Christian Thiess, M.D. Columbus (Ohio) Medical College, 1886; a member of the Ohio State Medical Association, and at various periods president, vice-president, secretary and treasurer of the Summit County Medical Society; was struck by a street-car, October 12, in Akron, and killed, aged 49.

Clarence Fay Wood, M.D. New York University, New York City, 1895; a practitioner and for six years president of West Winfield, N. Y.; a Fellow of the American Medical Association; aged 39; was killed at Clayville, October 8, by a collision between his motor-car and a train.

Vannie E. Smith, M.D. Kentucky School of Medicine, Louisville, 1894; a member of the Kentucky State Medical Association and a practitioner of Powersville; died recently at the home of his sister in Covington, Ky., from carcinoma of the stomach, aged 44.

Edwin Clifford Town, M.D. Jefferson Medical College, 1873; a Fellow of the American Medical Association; chief medical examiner in the relief department of the Pennsylvania Railroad; died at his home in Narberth, Pa., September 29, from nephritis, aged 63.

Joseph Neely Hopkins, M.D. College of Physicians, Keokuk, Iowa, 1885; a Fellow of the American Medical Association; for many years a practitioner of Burnt Prairie, Ill.; died at the home of his sister in Princeton, Ind., October 7, from neuritis, aged 67.

Seiler Joseph Aspelund, M.D. University of Minnesota, Minneapolis, 1906; a Fellow of the American Medical Association; for two years assistant city physician of Minneapolis; died at his home in that city, September 26, from heart disease, aged 33.

Frank D. Whiteacre, M.D. University of Michigan, Ann Arbor, 1894; for twenty-eight years a practitioner of Romulus, Mich.; postmaster of that town and a member of the school board; died at the home of his cousin in Detroit, September 14.

A. Marshall Stephens, M.D. Hahnemann Medical College, Chicago, 1884; formerly a clergyman and member of the faculty of Hamline University; died at his home in Red Wing, Minn., September 21, from cerebral hemorrhage, aged 71.

Edmunds Marshall Bloomfield, M.D. University of Michigan, Ann Arbor, 1869; formerly a Fellow of the American Medical Association; a member of the Indiana State Medical Association; died recently at his home in Peru, Ind., aged 72.

Alexander M. Todd (license, Colorado, 1893); said to have been a graduate of the University of Iowa, Iowa City, and a practitioner for more than forty-three years; died in the Denver County Hospital, September 17, aged 68.

Horatio Henry Brown, M.D. University of La Salle, Sewanee, Tenn., 1898; a member of the Tennessee Medical Association; formerly of Sharon, Tenn.; died at his home in Jackson, Tenn., October 5, from uremia, aged 42.

Richard Dulaney Leith, M.D. College of Physicians and Surgeons, Baltimore, 1877; of Vienna, Va.; died in a sanatorium near Richmond, Va., September 27, from arteriosclerosis, aged 60.

Lingard I. Whiteford, M.D. College of Physicians and Surgeons, Baltimore, 1897; of Fullerton, Md.; died at the home of his mother in Parkville, Baltimore, August 8, aged 35.

Alfred Jefferson Wenner, M.D. Medico-Chirurgical College of Philadelphia, 1894; died at his home in Wilkes-Barre, Pa., September 15, from cerebral hemorrhage, aged 49.

George Washington Truitt; M.D. University of Maryland, Baltimore, 1889; died at his home in Carsonsburg, Md., September 4, from disease of the stomach, aged 61.

Albert B. Wolverton, M.D. Indiana Medical College, Indianapolis, 1873; of Wakarusa, Ind.; died in the Marion Soldiers' Home Hospital, September 14, aged 65.

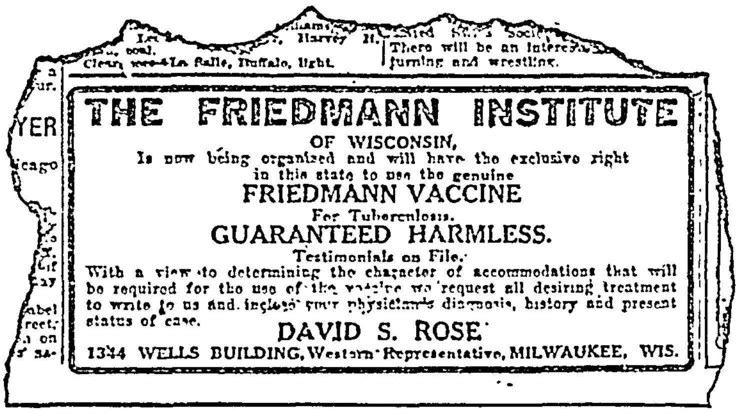
THE FRIEDMANN "CURE" LIBEL SUIT

An Attempt to Bluff the Journal Into Silence

As we went to press last week, the newspapers announced that a libel suit had been entered against the American Medical Association for $100,000, the libelous articles being those The Journal has published regarding the Friedmann "cure." The suit is brought in the name of Dr. J. J. Meyer. While the newspapers refer to him as a physician of Milwaukee, he is, as a matter of fact, a New Yorker, who represents the concern that is commercializing the Friedmann "cure," purchased, it is said, by the Eisner-Mendelson Company of New York.

So far, The Journal has not mentioned the name of any individual connected with the Friedmann exploitation in this country, the wretched business having been dealt with only in a general way. Now it becomes necessary to be specific. This Dr. J. J. Meyer, who suddenly steps into the limelight, seems to be employed by the "Friedmann Institute of New York, Inc.," to go about the country "demonstrating" the administration of the Friedmann product in behalf of the so-called Friedmann institutes. The "Friedmann Institute of New York, Inc.," is located at 90 West Street—the address of the Eisner-Mendelson Company, the reported purchasers of Friedmann's "cure." The letters sent out by the "Friedmann Institute of New York, Inc.," are signed by Moritz Eisner, president of the Eisner-Mendelson Company. The Eisner circulars describe Meyer as a "specialist in the administration of Friedmann's vaccine." In selling his professional services to aid and abet the Friedmann institutes in their methods of exploiting the tuberculous, Meyer disgraces the name of physician and deserves to be classed with other "consumption cure" promoters.



THE FRIEDMANN INSTITUTE

OF WISCONSIN,

Is now being organized and will have the exclusive right in this state to use the genuine

FRIEDMANN VACCINE

For Tuberculosis.

GUARANTEED HARMLESS.

Testimonials on File.

With a view to determining the character of accommodations that will be required for the use of the vaccine we request all desiring treatment to write to us and inclose your physician's diagnosis, history and present status of case.

DAVID S. ROSE

1334 WELLS BUILDING, Western Representative, MILWAUKEE, WIS.

Photographic reproduction of Rose's advertisement in Milwaukee newspapers. If the stuff really were a cure what should be thought of individuals who would brazenly advertise the "exclusive right" to the use of a remedy for the great white scourge? Note the claim: "Guaranteed harmless!"

Linked with Meyer's name is that of David S. Rose, who appears as one of Meyer's attorneys. Rose is the western representative of the Friedmann concern. He is something of a politician and will be remembered, at least by Wisconsin physicians, as an ex-mayor of Milwaukee; he also will be remembered by some for his connection with the "Twin Buttes Mining Company." In the minds of many Wisconsin physicians, Rose's connection with the Friedmann "cure" will merely confirm the opinions which they already hold, of both the man and the "cure." Rose has been writing to the Milwaukee newspapers, thus getting some free advertising both for the Friedmann "cure" and incidentally for David S. Rose. He claims to be an "authority on this subject and entitled to be considered as such." Rose tells the public that the Friedmann cure is a success! Physicians sufficiently expert to be employed by the United States government have declared otherwise. Rose expresses great confidence in the "cure"! A committee of the foremost physicians in Canada thoroughly investigated it and declared that "nothing has been found to justify any confidence in the remedy." Rose is enthusiastic in his praise of the "serum"! German physicians generally, and the Berlin profession in particular, condemn it. Rose thinks it a great therapeutic advance! Physicians from the Rhode Island State Sanatorium, reporting the results in 120 cases, state that patients who took the Friedmann "treatment" were worse off than if they had taken ordinary sanatorium treatment. The preposterousness of such a man as Rose posing as an authority on a subject of this sort ought to be evident to the public. Rose may be an authority on ward politics, he doubtless knows a good deal about mining propositions, and as a general all-around salesman he unquestionably has the advantage of physicians. When it comes to therapeutic products, however, he knows just as much about them as the veriest street-corner pedler who dispenses Dr. Quack's Sure Specific—and no more. That the defenders of the Friedmann "cure" are men of this type speaks volumes.

When the fallacy—if not fraudulence—and the danger of Friedmann's remedy came to be fully realized, it seemed evident that no high-class firm would have anything to do with the exploitation of the product. And none has. According to reports, the concern with which Friedmann finally concluded his commercial "dicker" was that of the Eisner-Mendelson Company of New York. It is not a company that from its history would inspire confidence. First incorporated in 1886 under the laws of Pennsylvania, it seems to have gone out of existence in 1892, to be immediately reincorporated under the same name in West Virginia. In 1900 the courts sustained an award of damages against the company for trade piracy. The company put on the American market a mineral water, the bottle and label of which infringed the rights of the owners of a well-known aperient water. The court declared that the company intentionally imitated the label "for the purpose of obtaining . . . a part of the good-will which the —— water had gained." The court went on to say that there was "nothing to show that it was not a case of undisguised piracy." The Eisner concern was assessed damages to the extent of approximately $30,000. In 1902 the company was again reincorporated, this time under the laws of New York. Still later —in 1907—there seems to have been one more reorganization, again under the same name but this time in the state of Maine! At various times the company has attempted to sell its stock to physicians and as late as May, 1913, a stock and bond concern of Chicago circularized physicians in a similar attempt, stating as an inducement, that "this company has lately acquired the Friedmann cure." It seems entirely fitting that such a concern should be the one to exploit Friedmann's grossly commercialized "cure."

The Journal is ready to meet in a court of law, on the proposition laid down, any individual, company or "institute" that is commercially exploiting the Friedmann "cure." It would be delighted to have the opportunity. But it will never be given the chance as, in its opinion, the present suit is a mere bluff. If the exploiters of the tuberculous think that they can intimidate The Journal of the American Medical Association from warning the consumptives of the country against the present disgraceful commercialization of the Friedmann "cure," they are badly mistaken.

ABSORBINE, JR.

Young's Panacea for Earthly Ills

Absorbine, Jr., is a liniment sold by W. F. Young, P.D.F. (whatever these letters may mean), Springfield, Mass. Like most "patent medicines," the claims made for Absorbine, Jr., seem to be limited chiefly by the legal restrictions on untruthfulness. Not long ago the label read:

> "Absorbine, Jr., removes any soft bunch without blistering or inconvenience."

Now the "lie direct" has made way for the "lie with circumstance," and the later label reads:

> "Absorbine, Jr. To remove soft bunches without blistering or inconvenience."

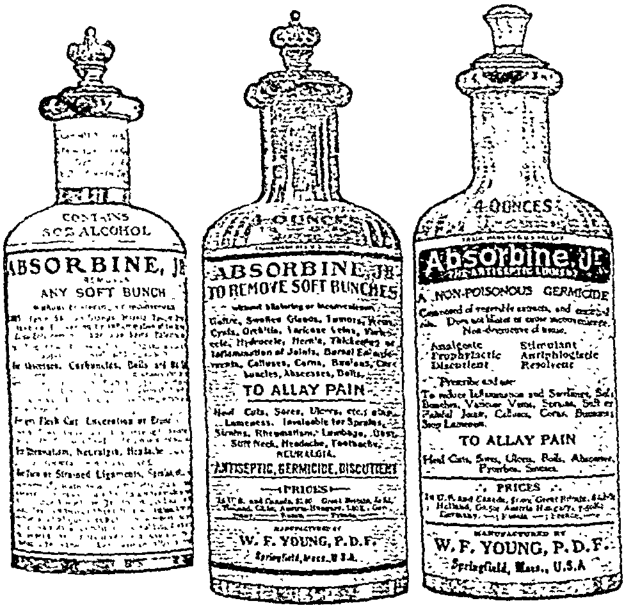
Absorbine, Jr., also used to "cure"—on the label—such things as goiter, rupture, orchitis and tumors. By inference, it still does so. In the booklet that comes with the bottle we used to read, under the title "A Discovery of Importance," this statement:

> "Absorbine, Jr., the Only Remedy Known that Positively Cures Varicose Veins. . . ."

Now, under the same heading, we read:

> "Absorbine, Jr., the Best Known Safe and Successful Remedy for Treating Varicose Veins. . . ."

Even in the 1913 packages of Absorbine, Jr., the stuff is inferentially sold as a cure for the following conditions: Rheumatism, neuralgia, headache, varicocele, orchitis, toothache, corns, goiter, dandruff, "catarrh," hay fever, piles, elephantiasis, milk leg, and several other conditions. In connection with the *liniment, Young also advertises, in the booklet* that is wrapped around the bottle, his "Combination Tablets No. 3." These are said to be a "homeopathic combination," which is said to "act specifically on the entire reproductive and *nervous systems . . .*" *Young's booklet gives* the impression that what "Combination Tablets No. 3" will not do is hardly worth mentioning. Nervous debility, uterine displacements, gonorrhea, carbuncles, aneurysm, goiter—these are but a few of the conditions that Young's Combination Tablets No. 3 will "overcome."



The evolution of a label! Three bottles of "Absorbine, Jr.," in varying stages of truthfulness. Note that the oldest bottle bears the legend: "Contains 50% Alcohol." In the stuff as now sold acetone takes the place of alcohol.

Both the carton in which Absorbine, Jr., comes and the booklet around the bottle contain a "reprint of a report of the Iamatological Bureau on the action of Absorbine, Jr." This sounds imposing and, from the prominence given it by W. F. Young, P.D F., is doubtless intended to be imposing. The report is by one Willard H. Morse, M.D., "Consulting Chemist and Therapeutist, Fellow of the Society of Science (London), American Director of Bureau of Materia Medica, etc."

As The Journal has said many, many times, Willard H. Morse is one of those parasites on quackery that furnish fake analytical reports. The fact that he is a "Fellow" of the "*Society of Science, Letters and Art (London)" in itself* arouses suspicion, for this so-called society is a seriocomic fraud to which quacks and others pay one guinea ($5) for the purpose of writing after their names the magic letters "F.S.Sc. (Lond.)." There may be a great many medical frauds that Morse has not reported favorably on, but we do not know of them. Epilepsy cures, tobacco-habit cures, consumption cures, fake dietary systems, frauds like the Oxydonor, Duffy's Malt Whiskey, Manola, Oleozone and the Ideal Sight Restorer—these are but some of the things for which Willard H. Morse, M.D., F.S.Sc. (Lond.), stands professional sponsor. How much the manufacturers of Absorbine, Jr., had to pay Willard H. Morse for his report we do not know, but whatever the amount, it was not worth it. Reports emanating from Morse's "bureau" are pretty rotten props for anything to rest on.

A bottle of Absorbine, Jr., was purchased in the open market not long ago and examined in the Association's laboratory. The chemist's report:

"Absorbine, Jr., is a clear, bright green liquid having a strong, penetrating, mint-like odor. From our examination it seems that the product is an acetone extract of some plant, probably wormwood, with the possible addition of some oil of sassafras and menthol. A product almost identical in physical appearance may be made from the following formula:

Oil of wormwood	1 dram
Oil of sassafras	16 minims
Menthol	15 grains
Acetone, sufficient to make	27 drams

Absorbine, Jr., is but another example of those fraudulent methods of exploitation that seem inseparable from the "patent medicine" business. Needless to say the stuff never cured a case of goiter or rheumatism or elephantiasis or hydrocele or varicose veins. Neither did "Young's Combination Tablets No. 3" ever "overcome" uterine displacements, gonorrhea or syphilis.

If Absorbine, Jr., were put on the market under a nonproprietary name and truthfully exploited, there would be very little of it sold. But enveloped in the mystery of secrecy and advertised with a reckless disregard for truth it, no doubt, *is a money-maker. As sold at present, it is a fraud.*

THE ARMY AND NAVY MEDICAL RECORD

A Fraudulent Publication Whose Editorial Opinions Are for Sale

Whenever a business assumes certain proportions, subsidiary businesses spring up to cater to the needs of the larger enterprise. For some years the nostrum business has grown so large that it has furnished a more or less precarious life for many individuals who have catered to it. There are, for instance, men whose *trade it is to obtain testimonials*; others, claiming a long string of imposing degrees, will furnish fake reports and bogus analyses; still others issue at irregular intervals publications with high-sounding names which sell editorial indorsement to the products of concerns such as are willing to pay the price asked. "Journals" of this type have been called to the attention of our readers at different times; the *New York Health Journal* and the *United States Health Reports* come to mind at this moment. Both of these had their day and died a natural death, as all such publications must when once the public is cognizant of their true character.

TWO LETTERS

More recently the attention of The Journal has been called to a publication calling itself the *Army and Navy Medical Record*. A physician in the South sends a letter he had received from the *Army and Navy Medical Record* reading as follows:

> "We have had many favorable reports reach us relative to your most excellent institution, and, as you are doubtless aware, we come in direct contact with a large number of Army and Navy and other government attachés who have sons that they desire to provide with a medical education combined with the higher course included in your up-to-date laboratory methods and the *sciences incidental to* clinical medical practice.
>
> "If you will regard the proposition as confidential, we will agree to carry a one-fourth page advertisement of your university at the nominal rate of $38 per year, provided this amount is forwarded in

advance at the time copy is furnished; and *we will further promise to editorially indorse and recommend your school and its methods without qualification or exception.* [Our Italics.—Ed.] This article you should be able to use (and are authorized to do so) after publication for advertising purposes.

"We will also be able, and are willing, to *furnish you with a desirable list of probable candidates from time to time.*

"Kindly let us hear from you at once, if interested, and oblige,

"Yours with best wishes,

"The Army and Navy Medical Record,
"Arthur G. Lewis, Managing Editor."

The physician to whom this was addressed made a notation on the letter to the effect that "this looks crooked." A few weeks later, Dr. V. C. Vaughan, dean of the University of Michigan, Department of Medicine and Surgery, sent in a letter from the *Army and Navy Medical Record* which he had received in his official capacity at the university. Here is the letter; again the italics are ours:

"We are gratified to advise you that in our efforts to select a strictly ethical and high-grade institution of medicine that this *magazine could consistently indorse and recommend,* we have decided on the University of Michigan, Department of Medicine and Surgery, as the institution in your territory to whom our special publicity *concession* will be made this year.

"You are doubtless aware that we come in direct contact with a *very large number of Army and Navy* and other government *attachés,* also physicians in private practice, who have sons that *they desire* to provide with a medical education, combined with the higher courses included in *your up-to-date methods.*

"For personal *reasons,* we are particularly anxious to favor *your* institution, and frankly believe that we can prove of material service *to you.* The *special proposition,* to be regarded *by you as* strictly confidential is that we will publish a full one-half page *announcement* of your *institution for the term* of one year, you to merely pay a nominal expense charge of $38 for the year's service. As our regular rate is $125 per *annum* for this service, *the necessity of regarding the matter between ourselves is apparent.* [Transparently so.—Ed.] We further propose, without expense to you, *to editorially indorse and recommend your* institution and its methods without qualification *or exception.* An electrotype illustration may be used, without charge.

"It is important, however, that we hear from you promptly Awaiting your immediate reply, we are, with best wishes,

"Yours faithfully,

"The Army and Navy Medical Record,
"Arthur G. Lewis, *Managing* Editor."

ARTHUR G. LEWIS
MANAGING EDITOR

PUBLICATION OFFICES
BALTIC BUILDING WASHINGTON D C

Editorial and Business Departments,
Maple Villa Sanitarium,
Hammonton, N J

August 16,1913.

Dr. Victor C. Vaughan, Dean,
University of Michigan,
Department of Medicine and Surgery,
Ann Arbor, Michigan.

Dear Sir:-

We are gratified to advise you that in our efforts to select a strictly ethical and high-grade institution of medicine that this magazine could consistently indorse and recommend, we have decided upon the University of Michigan, Department of Medicine and Surgery, as the institution in your territory to whom our special publicity concession will be made this year.

You are doubtless aware that we come in direct contact with a very large number of Army and Navy and other Government attaches, also physicians in private practice, who have sons that they desire to provide with a medical education, combined with the higher courses included in your up-to-date methods.

For personal reasons, we are particularly anxious to favor your institution and frankly believe that we can prove of material service to you. The special proposition, to be regarded by you as strictly confidential, is that we will publish a full one-half page announcement of your institution for the term of one year, you to merely pay a nominal expense charge of $38.00 for the years service. As our regular rate is $125.00 per annum for this service, the necessity of regarding the matter between ourselves is apparent. We further propose, without expense to you, to editorially indorse and recommend your institution and its methods without qualification or exception. An electrotype illustration may be used, without charge.

It is important, however, that we hear from you promptly. Awaiting your immediate reply, we are, with best wishes,

Yours faithfully,

THE ARMY AND NAVY MEDICAL RECORD.
Arthur G Lewis
Managing Editor

AGL:R

P.S.-Sample page attached, showing size, for your information.

Photographic facsimile of a letter sent by the Army and Navy Medical Record to the dean of University of Michigan, Department of Medicine and Surgery, offering one hundred and twenty-five dollars' worth of advertising space for a "nominal" thirty-eight dollars—with editorial indorsements and recommendations thrown in for good measure!

Dr. Vaughan, in forwarding the matter to The Journal, wrote that on receipt of the offer just given, he "was uncertain whether its writer was a knave or a fool." After inquiring into the matter somewhat thoroughly, he *concluded that* "the managing editor of the *Army and Navy Medical Record* is both a knave and a fool."

THE ARMY AND NAVY MAGAZINE

The Journal had the *Army and Navy Medical Record* under investigation before these two letters were received and, as a result, the following facts seem to be pretty well substantiated. Herbert C. Lewis, with his brother, Arthur G., conducted from Washington, D. C., a publication called the *Army and Navy Magazine.* In The Journal's nostrum file there is a booklet put out by the Renova Distributing Company describing the wonderful virtues of its product, "Anti-Jag," which, as its name might intimate, is a "liquor cure" of the fake variety. One page of this booklet is given over to what purports to be "A Letter from a Great Magazine Editor." The letter is dated June 19, 1900, from Washington, D. C., and says that "the editor of the *Army and Navy Magazine* takes pleasure in stating that from his own personal knowledge he has found 'Anti-Jag' to be one of the most reliable medicines ever introduced for the permanent cure of drunkenness." And more to the same effect. The letter is signed "Herbert C. Lewis, editor."

The publishing offices of the *Army and Navy Magazine* are at 606 F Street, N. W., Washington, D. C. The building at this address is known as the Baltic Building. Herbert C. Lewis is said to be a printer by trade.

The *Army and Navy Medical Record* seems to have been started within the last few months by Arthur G. Lewis. It does business from two addresses, the Baltic Building, Washington, D. C., and the Maple Villa Sanitarium, Hammonton, N. J. Lewis is said to have purchased the Maple Villa Sanitarium recently, but apparently his chief source of income is the *Army and Navy Medical Record.* He is alleged to have claimed that some medical officials of the government are interested with him in this publication but that these officials do not wish their names known. We do not blame them.

ADVERTISEMENTS AS EDITORIALS

A glance through two issues of the *Army and Navy Medical Record* makes perfectly plain the character of the publication. The January-February, 1913, number leads off with articles by well-known medical officers in the Army, the Navy and the Public Health Service. These have been copied from other publications. Then comes an editorial entitled "A Much Needed Dietary Reform," devoted to the laudation of "Postum," the widely advertised coffee substitute. Following this is an editorial on "The Philosophy of Hypnotics" in which aconitine, saline laxative and digitalin are each given a "boost." Then comes an "original article" (save the mark!) entitled "The Physiological Pathology of Consumption." This is by "Alfred S. Gubb. M.D., L.R.C.P., London, M.R.C.S., Eng., D.P.H., etc. etc., Aix-les-Bains, Savoie, France." Two pages are devoted to this. The "joker" appears in the third paragraph from the end—Fellow's Syrup of Hypophosphites. Dioxogen receives more than three pages of editorial mention under the caption "The Sterilization of Milk with Dioxogen." Under "Another New Electrical Wonder—Magnified Sound," the "Acousticon" is given a two-and-a-quarter page write-up. "What Wise Men Wear" is the title of a four-page article—unsigned—devoted to the laudation of suspensories in general and the "O-P-C Suspensory" in particular. Dr. H. F. Boatman, Los Angeles, contributes a short article on "A Case of Advanced Pulmonic Tuberculosis Treated with Injections of Dioradin," while our good old friend Willard H. Morse, M.D., "F.S.Sc. (Lond.)," the champion fake-testimonial-giver of the country, writes more or less entertainingly on "Putting on a Mustard Plaster." The article has nothing to do with mustard plasters but has a good deal to do with "Zumota," a nostrum recommended as a substitute for the mustard plaster. These are but a few of the nostrums to which the editorial and reading pages of the *Army and Navy Medical Record* are devoted.

In the June-July issue, Arthur G. Lewis becomes bolder. The leading article is entitled "First Aid in the Navy," by C. F. Stokes, Surgeon-General, United States Navy. There is nothing to indicate that this article was not contributed to the *Army and Navy Medical Record* by its author. As a matter of fact, it originally appeared in an official publication, the *United States Naval Medical Bulletin* for January, 1913, and was reprinted by Lewis without credit and without permission. Following the article by Dr. Stokes is another, unsigned, entitled "The Passing of 'The Pie Habit.'" This describes the surprise of the students of Harvard University at being served breakfast cereals instead of pie at their noonday meal and suggests that "Shredded Wheat Biscuits" make a "delicious dessert." A two-and-a-half page article on the "Danger of Corrosive Sublimate in Vaginal Douche" is reprinted from the *Lancet-Clinic* of September, 1903. The reason for resurrecting this ten-year-old article becomes apparent before one gets half through it. It deals not so much with the danger of corrosive sublimate as with the marvelous—alleged—properties of Tyree's Antiseptic Powder. Dr. Claude C. Keeler, Denver, has a three-page article on the "Medical Treatment of Pulmonary Tuberculosis." The "medical treatment" referred to is Waterbury's Compound. An editorial entitled "One Notch Ahead of Morphin" is devoted to that vicious morphin solution sold under the proprietary name "Papine." Another on "The Treatment of Catarrh by Palliatives and Curatives" deals with a widely advertised "patent medicine." "Kondon's Catarrhal Jelly." What appears to be a contributed article by Charles Wardell Stiles of the United States Public Health Service on "Country Schools and Rural Sanitation" has really been "lifted" from an official *publication without* credit and, needless to say, without Dr. Stiles' permission.

But medicinal preparations are not the only things to which the *Army and Navy Medical Record* gives editorial indorsement. All advertising matter, apparently, is grist to its mill. Sandwiched in between articles on "Public Health Administrations" and "Important Army Medical Lectures" is a dissertation on "The Millennium of Shirt Construction," in which are sung the virtues of the tailless shirt! A little farther along the Hawaiian pineapple is extolled, while the last pages of the issue are devoted to various banking concerns.

In addition to the advertisements appearing throughout the reading and editorial pages of these two issues of the *Army and Navy Medical Record*, there are a number of display advertisements. There is no reason to suppose, at least in the majority of cases, that the advertisers had the slightest reason to suspect the nature of the *Army and Navy Medical Record*. Several pages are devoted to financial advertisements, there being more than forty banks that have "fallen for" the wiles of Arthur G. Lewis. In view of the letters received by the deans of medical colleges and other educational institutions, the display advertisements of schools and colleges have a special interest to physicians. Schools for girls, polytechnics, colleges of music, veterinary, dental and medical schools—all are to be found in this cosmopolitan publication.

Among the therapeutic products advertised—in the advertising pages—are:

Fellows' Syrup of Hypophosphites	1	cover page
Sherman's Bacterial Vaccines	1	page
Kondon's Catarrhal Jelly	½	page
Expurgo Anti-Diabetes	½	page
Laxol	½	page
Campho Phénique	½	page
Palpebrine	½	page
Zumota	½	page
Sanmetto	¼	page

While in the reading pages the following products are puffed:

Tyree's Antiseptic Powder.
Waterbury's Compound.
Papine
Kondon's Catarrhal Jelly.
Ranier Natural Soap.
Iodia (Battle).
Creo-Derma.
Fellows' Syrup of Hypophosphites.
Tannalbin.
Expurgo Anti-Diabetes.
Zumota.
Sulfothen.
Dioxogen.
Palpebrine.
Bannerman's Intravenous Solution.
Daniel's Concentrated Tincture of Passiflora.
Peacock's Bromides.
Aletris Cordial Rio.
Gonosan.
Digipuratum.
Dioradin.
Pepto-Fer.
Lactol.
Campho Phénique.

Summed up: The *Army and Navy Medical Record* is but another of the parasites of quackery. It is not entered as second-class matter and it has probably no bona-fide circulation. While it is claimed to be "Devoted to the Interest of the Medical and Surgical Corps of the Army and Navy, the Public Health Marine Hospital Service and the Red Cross Society" it is actually devoted to none of these. It *is* devoted to the exploitation of the advertising public for the special financial benefit of the man who calls himself its editor—Arthur G. Lewis. Advertising contracts are obtained under false and fraudulent pretenses. In brief, Arthur G. Lewis is using the good name of the various medical services of the United States government to further his swindling operations. He has written letters to honorable physicians making dishonest and insulting propositions to deceive and defraud the public. Editorial indorsements of the *Army and Navy Medical Record* mean nothing except that money has been paid for them. In short, the *Army and Navy Medical Record* is a fraud, and its "editor," Arthur G. Lewis, a faker.

Correspondence

The Parasite of Rabies

To the Editor:—The paper of Noguchi on the "Cultivation of the Parasite of Rabies (*Jour. Exper. Med.*, 1913, xviii, 314; abstr., The Journal A. M. A., Sept. 20, 1913, p. 993), has a special interest for the student of hydrophobia. Is the cause indeed a parasite, or is it, as Ferran supposed, a ferment? Are the Negri bodies parasites, or do they simply enclose an invisible germ, the true parasite, of which the Negri corpuscle is the outward and visible expression? This view, which is probably at present the most illuminating, is represented by two admired and popular authors, Babes, who regards the Negri inclusions as the reaction of the cell to the parasite, and Prowazek, who classifies the parasite among the *Chlamydozoa.*. Both the parasite and the Negri bodies have been connected by some writers with the *Protozoa;* but in view of the fact that the Negri corpuscles are too large to pass through a filter, as the true parasite does, and that bodies similar and in fact identical have been found in healthy panthers by Cornwall, and in the fresh brains of cats by Luzzani, it will be understood that not much help could be obtained from them by any one who desired to form a critical estimate of the morphology of the rabies germ.

Noguchi, who appears to think that it is a *protozoon*, presents his theory in a slight setting of practical circumstances. This does not mean that he finds absolute certainty in his results, but rather that he would render further experiments convincing by backing them with comprehensive details. In his cultures of "street," "fixed" and "passage" virus, he observed "very *minute* granular and somewhat coarser pleomorphic chromatoid bodies." In "fixed" virus he found "nucleated round or oval bodies surrounded with membranes totally different from the minuter granular bodies," though they occur in the same culture. "The center is nuclear and the membrane is distinct and highly refractive." By inoculating animals with cultures of the "granular, pleomorphic or nucleated bodies, rabies has been reproduced in dogs, rabbits and guinea-pigs." It is not easy, it *must* be confessed, to distinguish between these bodies, but his nucleated oval bodies, surrounded by a very refractive membrane, resemble in their morphology the protozoa rather than the bacteria.

From this point of view, the *present* work of Noguchi is less disentangled from the early work of Pasteur, Roux, Memmo, Babes, Bruschettini, Grigorjew, and Rivolta than could be wished, for it is *constructed* on lines similar to theirs and Busila's. (*Compt. rend. Soc. de biol.*, July 31, 1908.) Busila's work, in fact, gives a foretaste of what may come, and is worth an attentive study, though it illustrates the limitations rather than the powers of the experimenter. He was able to find in the nerve centers and in the cerebrospinal fluid of animals infected with "fixed" virus a motile, sporing bacterium which grew on ordinary mediums, stained with Gram, and lived through 250 generations without losing its virulence. Cultures of this organism were first heated to 110 and subsequently injected into guinea-pigs, rabbits and dogs. The animals became rabid and their brains showed Negri bodies, but the most remarkable circumstance was the period of incubation, which was exactly what it ought to be after a genuine infection, being from seven to fifteen days after cerebral inoculation, and from fifteen days to three months after inoculation under the skin. Moreover, the brains of these animals produced rabies, which is certainly a point of primary importance.

Unfortunately, it is impossible to read these results with conviction. To Babes, who reviewed them without success, they seemed opposed to all our notions of the nature of infectious diseases ("Traité de la rage," p. 255). He could not confirm them. As an experiment in bacteriology, there is in their favor this fact, that they give a hint of the difficulties of the subject, of the difficulty under which all investigation has labored from the time when Hallier discovered in the blood of rabid animals his *Lyssophyton suspectum* (*Ztschr. f. Parasitenkunde*, 1869, i, 301), or Memmo his *Blastomycetes*, or Pasteur his granules. Others, too, have associated rabies with bacterium, as, for example, Mottet and Protopopoff (*Russk. 'atch.*, 1887, viii), who found a microbe which grew on ordinary mediums which produced paralytic rabies in animals. Though these experiments are interesting and curious, they are not convincing, and, moreover, they have failed to evolve the superb technic that will be indispensable to the man who is to isolate the true germ of rabies. It is probable that we have now passed through the crude phase of this investigation. The contribution of Noguchi is perhaps the nearest approach to the solution of the problem, unless the recent researches made by Luzzani (*Pathologica*, 1912-1913, v, 253) and Andreyewsky (*Sbornik. rabot. v. pam. I. M. Sadovskavo*, 1912, ii, 68) have attained the absolute solution.

Paul Bartholow, M.D., New York.

Comment on Sex Hygiene

To the Editor:—Your summary of newspaper comments on the problem of instruction in sex hygiene (Medical Economies, The Journal, Oct. 18, 1913, p. 1477), shows that we are one step ahead of the former generation—we recognize generally that it is a problem. It would be well, however, for the reformer, physician or layman, to recognize several other facts. In the first place, the greatest obstacle to the proper handling of the subject lies in the home. From my experience with large numbers of boys in private schools I know that the average boy of this type has, up to the age of 14 at least, no correct idea of sexual anatomy or physiology, while the public-school boy, though usually more wise, obtains his wisdom from a dangerous source. I have known many boys to whom another boy naked is a pleasing curiosity, while but very few know how animals propagate. This ignorance is of course due to the prudish reticence of the parents, and the curse of it is that the child of to-day is no further advanced than were the children of former generations. To say then that this question should be left to the home is to drop the matter entirely. We cannot expect aid from the very source which is presenting the obstacle.

It is therefore clear that it is up to the schools as the only organized medium available. But it is also plain that to make a sudden jump from the reticence of the home on all matters pertaining to sex to a direct discussion of sex hygiene in the schools would be as dangerous to the child as it would be abhorrent to the parent. If we could only stop crying reform, stop the warring between the sentiment surrounding innocence and the excitement over the moral results of ignorance, and treat the question from the point of view of educational science, the matter would be simple. Give the children more natural science taught by competent teachers—botany to the youngest, biology to the older ones, and anatomy and physiology to those of 10 or 12. The sexual side should not be emphasized but taken as a matter of course. With this foundation the teaching of sexual questions as such would cease to be a nightmare to parents or a side-show to children. Most important of all, we might reasonably hope that from such a course of study the parents of the next generation, who are the children of to-day, will treat the whole matter rationally, will make their children feel that the truths of sex are not an awful thing of mystery and shame that will be revealed some time in the dim future, but, like the working of the bowels, are things of great interest and importance, though they are not to be discussed at the dinner-table.

I have known boys who were fortunate enough to be brought up in homes in which they received proper instruction and explanation, and their true modesty and frank understanding of things sexual were distinctly refreshing after the prudery and morbid curiosity which are perfectly natural in the ignorant child.

W. B. H., Boston.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ACQUIRED IMMUNITY TO SMALL-POX

To the Editor:—1. Can acquired immunity to small-pox be transmitted to the offspring?

2. Does small-pox protect against bovine vaccination?

The following examples will bring out the reasons for the preceding questions:

Family A.—Five in the family, father previously vaccinated, mother unvaccinated, children exposed. One child had preliminary symptoms followed by slight eruption consisting of few pimples, one or two of which were pustular. Eruption lasted about a week, child not sick. The father and children were vaccinated at the same time. All four vaccinations were unsuccessful. Mother refused vaccination. No other cases in this family.

Family B.—Five members. Father previously vaccinated successfully when a child, also four or five times since without result. Children exposed. Mother and the three children were vaccinated. In two of the children vaccination was unsuccessful, also when repeated.

Family C.—Six members. Father previously vaccinated successfully when a child, also four times since without result. Mother has been vaccinated four times without result. Mother and four children vaccinated; two of the children without result; vaccination repeated on these two without result. This makes the third time for one of the children without effect.

Family D.—Seven members. Given as a control. All vaccinated, six successfully.

Robert P. Stark, M.D., Allegan, Mich.

Answer.—1. Many cases seem to indicate the possibility of the transmission of immunity to small-pox, but the phenomenon is quite exceptional.

2. Yes.

CONTRACTURE OF FINGERS IN HEMIPLEGIA

To the Editor:—1. Would the lengthening of the flexor tendons of the fingers in a case of hemiplegia of a year's standing in which the flexors overbalance the extensors be a procedure of much hope? The hand, when extended on the wrist, causes the flexion of the fingers into the palm. The joints are still seemingly normal. The power of flexion is good, but the patient cannot open his hand enough to grasp any large object well.

2. Do the tendons of the fingers unite when severed, like the Achilles tendon?

3. Would a lengthening operation or a division be the better?

4. Would there be any great danger of infection if no silk, for instance, were left in?

W. E. B., M.D.

Answer.—1. We do not think that lengthening of the flexor tendons of the fingers in a case of hemiplegia would be of any use in overcoming the contracture, due to paralysis. If there were no paralysis present the tendons could be lengthened with good result.

2. Tendons of the fingers unite when severed the same as other tendons, provided they are properly cared for.

3. If an operation were advisable it would be better to lengthen the tendons rather than divide them, as the retraction after simple division is too great and union might fail on account of wide separation of the ends.

4. The best material for suturing or lengthening tendons is silk. The silk should be prepared according to Lange's method, which consists in boiling it in 1:1,000 mercuric chlorid solution. Such silk would remain indefinitely without danger of infection, provided the operation was aseptically done.

DIFFERENCE BETWEEN HEREDITARY AND CONGENITAL SYPHILIS

To the Editor:—What is the essential difference between hereditary and congenital syphilis? W. R. A., Lincoln, Neb.

ANSWER.—The terms are used interchangeably to indicate the condition of syphilitic infection manifest at birth. Syphilitic disease might be latent in the infant at birth, and developing subsequently could not be called congenital, but it would still be hereditary. Some would go so far as to say that syphilis cannot be hereditary on the assumption that no disease can be inherited. This is an unproved assumption which it would be unprofitable to discuss. We may say at least that it is still generally assumed that diseases can be inherited or transmitted from parent to child, and the important question is whether syphilis can be so transmitted. The discovery of the *Spirochaeta pallida* has made it possible to explain the way in which this transmission can be brought about. Experimental observations show that the semen may contain the spirochetes and hence the disease may be directly transmitted from the father to the fetus in conception. The mother may transmit the disease either by the presence of the germs in the ovum or by infection of the placenta, or the passage of the spirochetes from the blood of the mother to the blood of the fetus. The mother may herself become infected from the fetus, although the proof of this occurrence is not positive. The long period of latency during which the germs of inherited syphilis sometimes lie dormant lend some support to the hereditary character of those cases which have been observed in the third generation.

WORKS ON HELMINTHOLOGY

To the Editor:—What are some of the best and recent works on intestinal parasites, or helminthology? Did not Loos write an exhaustive treatise on this subject? If so, where can it be obtained? W. H. H., Deridder, La.

ANSWER.—The following works may be referred to. We are unable to find any record of a book written by Loos on this subject.

Braun, M.: Animal Parasites in Man. Wood. Price, $5.
Braun and Luhe: Practical Parasitology, Wood. Price, $3.50.
Welter, Carl: Ein Fall von Balantidium Coli im Darmkanal des Menschen. Bonn, Ludwig, 1912.
Stiles, C. W., and Garrison, P. E.: A Statistical Study of the Prevalence of [illegible] Man, *Hyg. Lab. Bull.*, 28.
Stiles, C. W.: A [illegible] the Intestinal Parasites of Five Hundred [illegible] at the U. S. Government Hospital for the Insane. *Hyg. Lab. Bull.*, 13. (Cannot be obtained from government.)
Stiles, C. W.: Illustrated Key to the Trematode Parasites of Man, *Hyg. Lab. Bull.*, 17. (Cannot be obtained from government.)
Stiles, C. W., and Hassall, A.: Trematoda and Trematode Diseases, Index-Catalogue of Medical and Veterinary Zoology, *Hyg. Lab. Bull.*, 37. (Can be obtained from Superintendent of Documents, Government Printing Office, Washington.)
Stiles, C. W., and Hassall, A.: Cestoda and Cestodana, Index-Catalogue of Medical and Veterinary Zoology *Hyg. Lab. Bull.*, 85. (Address the Surgeon-General, U. S. Public Health Service, Washington, D. C., for this.)

Bulletins which cannot be obtained from the government may perhaps be found at medical libraries.

MINE CONDITIONS DELETERIOUS TO THE RESPIRATORY SYSTEM

To the Editor:—Please refer me to literature on mine conditions (gases, dust, etc.) deleterious to the respiratory system.
A. M. GIDDINGS, Crosby, Wyo.

ANSWER.—The following may be referred to:

Oliver, T.: Dangerous Trades. New York, Dutton. Price, $8.
Systematic Prevention of Mine Accidents, THE JOURNAL, Current Comment, April 5, 1913, p. 1081.
Committee on Resuscitation from Mine Gases, THE JOURNAL, Proceedings of Minneapolis Session, June 21, 1913, p. 2002.
Sommerfeldt, T.: Danger from Explosion of Gases in Mining, *Norsk Mag. f. Laegeridensk.*, February, 1913; abstr. in THE JOURNAL, March 15, 1913, p. 874.
Oliver, T.: Dust and Fumes, the Foes of Industry, THE JOURNAL, Society Proceedings, Oct. 5, 1912, p. 1315.
Lindemann, W.: Accidents and Diseases of Miners and Tunnel Workers, THE JOURNAL, Society Proceedings, Oct. 5, 1912, p. 1315.
Haynes, J. R.: Death in Mines of America Reasons for a Federal Commission, *South. California Pract.*, January, 1912.

Further information may be obtained by communicating with the American Mine Safety Association, Pittsburgh, Pa., and the American Association for Labor Legislation, 1 Madison Avenue, New York City.

FIBROLYSIN

To the Editor:—Please give me any information that you may have on fibrolysin. S. L. W.

ANSWER.—Fibrolysin is a name given to a solution of thiosinamin sodium salicylate, and is described in N. N. R., page 258. This substance, it is claimed, has the power of causing the absorption of cicatricial tissues. It has been used for the removal of cicatrices resulting from burns, etc. In some cases it has seemed to be quite successful, although there have been numerous failures.

CORRECTION OF ALGEBRAIC EXPRESSION

To the Editor:—In THE JOURNAL of Sept. 27, 1913, page 1134, second column, second paragraph, fifth line, should not $\sqrt{r^{12}-y^2}$ read $\sqrt{r'^2-y^2}$? J. A. BACHER, M.D., San Jose, Cal.

ANSWER.—Our correspondent is correct, and the latter notation is the right one.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POSTGRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

AN IMPOSSIBLE PROPOSAL

Hon. T. L. Reilly, member of congress from Connecticut, has introduced the following in the House of Representatives:

A bill to create a United States Medical Licensing Board.

Be it enacted by the Senate and House of Representatives of the United States of America in congress assembled, that the president be, and he is hereby, authorized and directed to appoint two medical officers of the United States Army, with a rank of a captain and a major; two medical officers of the United States Navy, with rank of lieutenant and lieutenant commander; and two medical officers of the United States Marine Hospital Corps, with rank of lieutenant and lieutenant commander, to a board to be known as the United States Medical Licensing Board.

SEC. 2. That the terms of the members of the board to be four years each, and the salary of each member thereof to be $4,000 per annum with mileage. Said board shall be in continuous session at Washington when not on duty in various states.

SEC. 3. That all regular licensed medical practitioners of medicine, now holders of a medical diploma and a state license permitting them to practice in the respective states, shall upon the passage of this Act by presenting to said board their medical diploma, their state medical license, and any other diplomas they may have, and upon the payment of the sum of $2 be given a United States license which will permit them to practice their profession of medicine in any state or territory of the United States and its possessions.

SEC. 4. That the United States Licensing Board shall hold its meetings in various cities of the United States and shall examine all newly graduated medical doctors so that they may obtain a United States license, which license will permit them to practice medicine or surgery in any state or territory of the United States and its possessions without any further examination: *Provided*, That the candidate for said license shall fulfill all the requirements of the American Medical Association and shall be an American citizen and present a high-school certificate or its equivalent and shall have a doctor of medicine diploma from a medical college in good standing, as declared by the American Medical Association, and upon the payment of $10 and the filing of certificates of good moral character shall be admitted to examination and upon the passage of said examination shall be granted a United States license, which will permit the holder to practice medicine and surgery in any state or territory of the United States and its possessions.

SEC. 5. That the license may be revoked in case abortions or other unprofessional and criminal acts are performed.

Without questioning the sincerity or good intentions of the introducer of this measure, it must be recognized that the provisions contained in Mr. Reilly's bill are entirely impracticable. In any other nation national regulation of the practice of medicine might not only be considered, but in practically every other civilized nation such national control is in effect. In the United States, however, the regulation of the practice of medicine comes under the police power of the state, and is consequently, under the jurisdiction of state legislatures and not under that of congress. This is a fundamental fact, which has been recognized by all law-making bodies and by all courts, from the United States Supreme Court down. The consideration of any measure by congress, providing for the regulation of the practice of medicine in the states by any federal board, is, therefore, simply a waste of time, as any such measure, even if adopted, would be declared unconstitutional as soon as it came into court.

Aside from this objection, which is, of course, fatal to the bill, criticism might be made of the provision limiting the appointment of members to officers of the government services. A more serious objection, however, is the loose phraseology in Section 4, providing that "the candidate for said license shall fulfill all the requirements of the American Medical Association." There are no specifications as to what requirements are referred to. Certainly, the provision by which an examining board would delegate the formulating of specifications for licenses to a voluntary organization would be most unwise. A similar objection would lie against the provision that recognized medical colleges should be limited to those approved by the American Medical Association. The provision requiring only a high-school certificate for admission is hardly in harmony with the present effort to raise the educational standards of medical schools. Section 5 provides for the revocation of licenses in cases of "unprofessional" acts; but does not specify what acts shall be considered "unprofessional." These criticisms, however, are superfluous, as the provision for federal jurisdiction over the practice of medicine in the various states is essentially unconstitutional, and, consequently, any such bill as that proposed by Mr. Reilly is a legal impossibility. This bill, which deals with an important social problem, was referred to the House Committee on Military Affairs. Such a reference is ridiculous, and only emphasizes the shortcomings of the system of committees in the house and the need of a Committee on Public Health.

THE PRESENT LEGAL STATUS OF OSTEOPATHY

Attention has been called to an error in the issue of The Journal for September 20, 1913, p. 981. In the article on "The Present Legal Status of Osteopathy," New Hampshire is listed among those states having separate osteopathic boards of examiners. This is incorrect, as a reference to the law will show. The medical practice act of New Hampshire stipulates that its provisions shall not apply to "persons practicing . . massage . . . or any other method of healing if no drugs are employed or surgical operations are performed; provided that such persons do not violate any of the provisions of this act in relation to the use of M.D. or the title of doctor or physician" (Act of 1897, Section 11, as amended by Ch. 1. Session Laws, 1903).

In the same article under the subtitle, "Is Osteopathy the Practice of Medicine?" the several states were listed in accordance with judicial and statutory interpretation of the term "practice of medicine." Under this arrangement, Kentucky was placed among those states which hold osteopathy to be not the practice of medicine. This was on the authority of the decision in Nelson *v.* State, 108 Ky. 769, 50 L. R. A. 383. That case, however, has been negatived by statutory amendment which provides that the words "practice of medicine" in this act shall be held to include the practice of osteopathy. But no such persons may practice without a diploma and they are forbidden "to administer drugs or to perform surgical operations with the knife." This is in accordance with the act of 1904, Section 6.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arkansas: Regular, State Capitol Bldg., Little Rock, November 11-12. Sec., Dr. W. S. Stuart, Suite 404 Citizens Bank Bldg., Pine Bluff; Homeopathic, Little Rock, November 11. Sec., Dr. Ida J. Brooks, E. 10th St.; Eclectic, Little Rock, November 11. Sec., Dr. C. E. Laws, 712 Garrison Ave., Ft. Smith.

Connecticut: Regular, City Hall, New Haven, November 11. Sec., Dr. Charles A. Tuttle; Homeopathic, New Haven, November 11. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.; Eclectic, New Haven, November 11. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

Florida: Jacksonville, November 12-13. Sec., Dr. J. D. Fernandez.

Louisiana: New Orleans, October 27-29. Sec., Dr. A. B. Brown, 34 Cusachs Building; Homeopathic, 702 Macheca Bldg., New Orleans, November 3. Sec., Dr. Edward Harper, New Orleans.

Maine: City Hall, Portland, November 11-12. Sec., Dr. Frank W. Searle, 776 Congress St.

Mississippi: Jackson, October 28-29. Sec., Dr. E. H. Galloway, Jackson.

Nebraska: Lincoln, November 12-13. Sec., Dr. H. B. Cummins, Seward.

Nevada: Carson City, November 3. Sec., Dr. S. L. Lee, Carson City.

South Carolina: Columbia, November 11. Sec., Dr. A. Earle Boozer, 1806 Hampton St.

Texas: Bender Hotel, Houston, November 11-13. Sec., Dr. W. L. Crosthwait, Suite 1003, Amicable Bldg., Waco.

West Virginia: Hotel Chancellor, Parkersburg, November 10. Sec., Dr. S. L. Jepson, Wheeling.

Higher Standards in Michigan

Official word has just been received that, at a recent meeting, the Michigan State Board of Registration in Medicine adopted a resolution increasing the requirement of preliminary education, of those seeking licenses to practice medicine in that state, to one year of collegiate work in addition to a four-year high-school education. The additional year is to include college courses in physics, chemistry, biology and a modern language. This is the fourteenth state in which one or two years of collegiate work now constitutes the minimum preliminary requirement. The complete list follows:

State Licensing Board of	No. of Years Required	Affecting Students Matriculating	Affecting All Applicants
Minnesota	2	1908-09	1912
North Dakota	2	1908-09	1912
Colorado	2	1910-11	1914
Connecticut	1	1910-11	1914
Kansas	1	1910-11	1914
Indiana	2	1910-11	1914
Utah	1	1910-11	1914
Iowa	2	1911-12	1915
South Dakota	2	1911-12	1915
Vermont	1	1912-13	1916
Pennsylvania	1	1913-14	1917
Kentucky	2	1914-15	1918
Michigan	1	1914-15	1918
California	1	1915-16	1919

CHIEF NEEDS FOR AND FUNCTIONS OF THE FEDERATION OF STATE MEDICAL BOARDS*

N. P. Colwell, M.D.

Secretary of the Council on Medical Education of the American Medical Association

In every country having a standing comparable with that of the United States, the national government, through one or more bureaus, has always kept direct or close control of educational institutions and of the licensing of physicians. As a consequence these matters have always been systematically looked after, medical schools have never been separated from universities, and there never has been the chance for irregular or low-grade institutions calling themselves medical colleges, to gain a foothold; therefore, such institutions have never been known. Every medical college as a rule is the medical department of a government-owned or controlled university, so has always been conducted on the same high plane as other educational institutions. Again, the licensing of physicians seems to have always been in the hands of thoroughly competent officials who have in charge such matters for the entire nation, so if a candidate does not present proper credentials, or if he fails to pass the required examinations, he simply cannot procure a license to practice in any part of the country. He must make up his deficiencies or not secure his license.

---

* From the *Quarterly* of the Federation of State Medical Boards of the United States, October, 1913, p. 20.

CONTROL IN THE UNITED STATES

In the United States, on the contrary, the national government assumes no responsibility regarding either education or the licensing of physicians, these matters having been left by the Constitution to the individual states—a responsibility the importance of which even to-day has not been fully realized or fully assumed by many if not by the majority of states. In our forty-nine states there are forty-nine different medical practice acts which, for their enforcement, have been placed in the hands of sixty-two different boards, sometimes two or three to a state! To make the matter still more serious, in seventeen states there are also separate boards having entire authority over osteopaths—an arrangement which doubtless protects them in practicing as they see fit, including surgery and the administration of drugs!

EVILS DUE TO THIS CONFUSION

Is there any wonder, with this confusion, that bogus and low-grade medical schools and schools for every fad in the category grew up like toadstools? Is it a wonder that these heterodox institutions have flooded the country with half-baked, illiterate and incompetent "doctors," who, even though they may have been rejected by one state fortunate enough to have a good law administered by a good board, easily secure licenses in some other state—or if persistent, or if possessing a sufficiently strong political pull, finally succeed in securing a right to prey on the people of the very state where they were rejected in spite of the efforts of the state's valiant defenders?

Through this confusion also we see notorious quacks, abortionists, spurious patent medicine venders and other undesirables finally, if not easily, securing the right to carry on their nefarious practices in some state or other even though they may have been rejected or have had their licenses revoked in one or more other states! Or, even after they have had their licenses revoked by some strong board we sometimes see them brazenly continuing to practice, made immune to prosecution through political affiliations, thus snapping their fingers at the only safeguard the state has placed between the public and these vandals. The protection of the public against such evils *from a national standpoint* is practically a farce and the conditions would be laughable were they not so exceedingly serious. We have very often heard it stated — which is a fact — that the control of these matters "has been left to the police-powers of the various states." True, but how are these "police-powers" working out? States could be named which have established no "police-power" worthy the name, or which permit conditions to exist which are practically intolerable. Many still have ineffective laws and some have fair laws but incompetent political favorites to enforce them, and as a consequence the public have no safeguards; other states have fair laws except that two or three separate boards have been established to carry out their provisions, consequently either all boards are "easy" with their respective followings or serious discriminations result. Even some of the states having the best practice acts for regulating the licensing of physicians have inconsistently provided separate boards for osteopaths (often self-styled "osteopathic physicians").

ONE EDUCATIONAL STANDARD NEEDED

Meanwhile, when are we going to learn—when are our legislators going to learn, that before any method of "healing" can be safely applied to a sick or suffering human being, the "practitioner" must be sufficiently well educated to make a diagnosis, to *know* what disease he is attempting to treat and to *know* whether his particular "specialty" is the one to be used or whether it is the very one most dangerous to the patient? When is the fact going to be recognized that one standard—an educational standard—should be applied *to every* practitioner of the healing art regardless of the particular "system" of treatment he may represent? In fact, the whole mess of fads, diploma mills, low-grade colleges, quacks, impostors and the like never could have been, or could easily have been nipped in the bud had it not been for the politics-ridden and ineffective "police-powers" in many of the states. Take the very best conditions existing in any state and even then the safeguards are less effective than in most European countries. On the other hand, they should be even more effective because of the general confusion in control of these matters throughout the country. I have said "less effective than in most European countries" advisedly. Germany, for example, requires the candidate to have been trained in one of the governmental university medical schools and then requires the passing of an examination unusually severe. Again, I believe it will be acknowledged that in no state is the examination of candidates for license as searching and thorough as that given by the Conjoint Board of England, so ably outlined two years ago by Mr. Frederick G. Hallett, the secretary of the board. The examinations as usually given in this country still lack the searching laboratory and clinical tests which really permit a graduate of a medical school with adequate laboratory and clinical facilities to show his superiority over the candidate trained by the memorizing methods of the low-grade colleges which lack essential equipment. True, some boards have made a beginning, nevertheless almost every candidate, including graduates from some seriously low-grade colleges, succeeds in passing the examination. Of the candidates examined by the Conjoint Board of England there are almost always as many as 28 to 35 per cent. who fail.

STATE BOARD MEMBERS THE GREATEST HOPE

These statements must not for an instant be taken as a reflection on the officers of our state medical licensing boards, many of whom have striven valiantly against almost insurmountable obstacles to do their full duty. On the contrary it is these men above all who have recognized and are familiar with the conditions to which allusion has been made. It is to the men on our state licensing boards chiefly that the nation must look for better safeguards against the evils enumerated. Meanwhile, improvements have been going on for twenty years or more; conditions have been much worse. There is no better place to pay a most deserved tribute to one state board secretary, who, during the twelve years from 1878 to 1890, did more to raise the standards of medical education and medical licensure than any other man of his time. He likewise exposed and caused the closure of some fifty or sixty diploma-mills which prior to that time were having free rein. His reports, furthermore, constitute the most reliable account of medical colleges existing during and prior to his time. I refer to Dr. John H. Rauch, one-time secretary of the Illinois State Board of Health. Other state board officials could be mentioned who, without adequate pay, and facing opposition from the very persons from whom support was expected, carried on vigorous and effective campaigns in the interest of the public. Even though this is a dark picture, it is no more dark than could be drawn regarding the ineffective control of other matters, commercial and otherwise, which are due to our complex and politically-influenced city and state "police-powers." The important thing is for medical men and especially those on state boards to recognize the defects in connection with these medical matters, take stock of the hindrances, and all together, through the Federation of State Medical Boards and other agencies working toward the same end, press the campaign for betterment.

SOME OF THE REASONS FOR THE PRESENT CONDITIONS

Briefly stated, the causes for the present complexity of conditions, speaking from the national standpoint, are as follows:

1. Instead of one controlling factor there are sixty-two boards, each of which has no legal connection with, or responsibility for, the work of the other sixty-one boards.

2. These boards are hampered in many respects, varying with different boards, such as by (*a*) poor laws, (*b*) bad

politics, (*c*) unskilled board members, (*d*) conflicting boards, (*e*) lack of provision for skilled examiners, (*f*) lack of full-time officials, (*g*) lack of ample funds with which to do things, and (*h*) lack of ample authority to do what is needed.

3. Lack of direct control of the chartering of new colleges.

4. Difficulty (formerly) of securing accurate knowledge of conditions underlying medical education and licensure in different sections of the country, and again the lack of officers, time and money which would permit of wholesale campaigns of investigation such as have been voluntarily carried on by the American Medical Association through its Council on Medical Education.

Note: Even if each board had possessed all that was needed for such tours of inspection, it is a question whether such work conducted by all boards individually would be desirable. It would be poor economy, be an awful nuisance to the medical colleges thus inspected and—worse yet—could only result in a multiplicity of conflicting standards.

5. Lack of information regarding what other state boards are doing. All states are not warned against quacks, charlatans or other undesirables to whom licenses are refused by one state, nor do they as a rule learn the fact if one state revokes a license for unprofessional conduct. All boards should be informed of such matters. Here is a suggestion for the new State Board *Quarterly*.

6. Lack of money, means or skill to conduct examinations which will bring out the applicant's real training instead of his being merely able to memorize book knowledge.[1]

We have, therefore, viewing the situation from the national standpoint, a very complex system with sixty-two different boards, having no legal cohesiveness, and each having the final word in its own district. There is no central authority over these boards, and at present there is no strong influence by which they can be brought to work in harmony for the best welfare of this great country, for uniformly high standards and for equally effective methods of examination and licensure. It is working along these lines that the Federation of State Medical Boards can do the greatest good.

WHAT THE FEDERATION OF STATE BOARDS SHOULD BE

(*a*) A moral force standing above the individual boards, supporting the good work being done and extending knowledge of proved methods to other boards.

(*b*) A moral force tending to unify the efforts of all boards, thereby securing a better enforcement of laws now existing, and urging better laws in states where such are needed.

(*c*) An influence toward a rapid extension of reciprocity in medical licensure.

(*d*) An organization through which impostors, incompetents or other undesirable practitioners can be prevented from securing the right to prey on the public in any state.

(*e*) An organization which will influence the general adoption of a single and fair educational standard for measuring all candidates for the license to practice the healing art by whatever form of treatment.

(*f*) An organization which will be in position to solve the problem of providing a single examination which will be so thorough as to command recognition by all state boards, along the lines of the Conjoint Board of England or the new Dominion Examination just provided for in Canada.

(*g*) An organization to study the needs of various boards and through publicity to help secure those needs; *not to usurp the authority of the individual state boards but to secure the cooperation of all boards, by which such authority may be made more effective.*

The greatest work of the Federation will be to secure complete protection of the people of the entire country against those who are not properly trained in the medical sciences, where now, although some parts of the country may be protected, other vital parts are seriously exposed.

The present confusion and ineffectiveness in the control of medical licensure and medical education, even as does the confusion existing in divorce laws, in commercial matters and in other departments of public life, sometimes lead one to despair of the future of the form of government in the United States, the land of the free, where there is too little control over the lawless elements, who always abuse the liberties given to them.

The medical situation demands the unifying and correlative influence of an organization national in its scope, and in work along this line is the Federation's great opportunity.

---

[1] Many state laws prohibit teachers in medical colleges from being members of the licensing boards; nevertheless they are the most skilled examiners. Could they not be called into service by a similar plan to that used by the Conjoint Board of England? (See A. M. A. Bulletin, March 15, 1912, p. 160.)

Book Notices

HIMSELF. Talks with Men Concerning Themselves. By E. B. Lowry, M.D., and Richard J. Lambert, M.D., Cloth. Price, $1 net. Pp. 193. Forbes & Co., 1912.

SEX EDUCATION. By Ira S. Wile, M.S., M.D. Cloth. Price, $1 net. Pp. 150. New York: Duffield & Co., 1912.

THE THREE GIFTS OF LIFE. A Girl's Responsibility for Race Progress. By Nellie M. Smith, A.M., Lecturer for the Society of Sanitary and Moral Prophylaxis. New York, with an Introduction by Thomas Denison Wood, A.M., M.D., Professor of Physical Education, Columbia University. Cloth. Price, $0.50 net. Pp. 138. New York: Dodd, Mead & Co., 1913.

HEALTH AND HAPPINESS. A Message to Girls. By Eliza M. Mosher, M.D., Lecturer on Special Anatomy, Physiology and Hygiene for Women, Chautauqua School of Physical Education. Cloth. Price, $1 net. Pp. 203, with illustrations. New York: Funk & Wagnalls Company, 1912.

INSTEAD OF "WILD OATS." A Little Book for the Youth of Eighteen and Over. By Winfield Scott Hall, Professor of Physiology, Northwestern University Medical School. With a Foreword by Edward Bok. The Edward Bok Books of Self-Knowledge for Young People and Parents, of Which This is Number Three. Cloth. Price, $0.25 net. Pp. 62. New York: Fleming H. Revell Company, 1912.

HOW SHALL I TELL MY CHILD? By Mrs. Woodallen Chapman. With a Foreword by Edward Bok. The Edward Bok Books of Self-Knowledge for Young People and Parents, of Which This is Number One. Cloth. Price, $0.25 net. Pp. 62. New York: Fleming H. Revell Company, 1912.

The growing interest in sex hygiene is well illustrated by the increasing number of books on the subject which are being offered to parents, schoolteachers, and even to children themselves. The group above is typical.

"Himself," by Dr. Lowry and Dr. Lambert, is one of a series of books for different ages and classes. This one is a talk with men concerning themselves. It covers a wide range of topics, including not only the usual subjects treating on sex hygiene, but also such questions as the limitation of offspring, sterilization of the unfit, medical fakes and how to defer old age.

"Sex Education," by Dr. Wile, is written for the assistance of parents and to suggest a plan for parental instruction of children.

Mrs. Smith's book, "The Three Gifts of Life," is addressed directly to girls themselves, leading the young readers by introductory chapters on plant and animal life up to a discussion of human life and its reproduction.

"Health and Happiness, a Message to Girls" by Dr. Mosher, is in the form of a series of letters and covers not only sex hygiene, but many other questions of interest to young girls. The chapters on the care of the skin and hair and the discussion of clothing ought to help in counteracting the influence of the everywhere prevalent "beauty column."

"Instead of Wild Oats" and "How Shall I Tell My Child" are parts of the Edward Bok series, the first being written for boys of eighteen and over and the second for parents.

The essential facts in sex hygiene are few and comparatively simple. The entire value of any book or pamphlet on this subject depends on the manner of presentation and the scientific accuracy of the statements. The growing tendency of all of this literature is to abandon the sensational and unscientific statements which characterized the early stages of this crusade and to appeal to the reason and the higher instincts rather than to fear. In this particular, the quality of these books from a pedagogic standpoint has improved enormously of late years. A few years ago the question was, "Where can I find something suitable?" To-day the question is to choose from the amount of literature offered. Any of the books listed above can be safely recommended for the purpose for which they are intended.

Human Physiology. By Prof. Luigi Luciani, Director of the Physiologic Institute of the Royal University of Rome. Translated by Francis A. Welby. Edited by Dr. M. Camis, with a Preface by J. N. Langley, F.R.S., Professor of Physiology in the University of Cambridge. In Four Volumes. Volumes One and Two. Cloth. Price, $5.25 each. New York: The Macmillan Company, 1913.

This extensive work, which has run through a number of editions in the Italian and which has been translated into several languages, has not heretofore appeared in English. The first volume covers the subjects of circulation and respiration, the second volume internal secretion, digestion, excretion and the skin. The book states conclusions from physiologic research and also enters largely into the history and the literature regarding them. The attitude of the author in regard to the phenomena of life, in contrast to that of some of the German physiologists, is stated as follows: "No sincere worker in the positive or scientific direction can deny that the specifically vital somatic phenomena, i. e., those by which living beings are differentiated from inorganic bodies, are inexplicable by the known laws of chemistry and physics, and . . . are altogether remote from mechanical explanation." An interesting feature of the book is the assertion of the author that to Cesalpinus rather than to Harvey is to be given the credit for the discovery of the circulation of the blood. The author also disputes the theory of the hormones as expounded by Bayliss and Starling, with regard both to digestion and the theory of fetal hormones. The discussions of physiologic phenomena throughout are brilliant and informing. The progress of research in the chemistry of digestion and in the internal secretions is so rapid nowadays that, as might be supposed, the work does not include theories and findings of the past two or three years, which would undoubtedly cause the author to modify some of his statements. In the chapters on digestion, the movement of the stomach and intestines, as revealed by recent research with the Roentgen ray, are not touched on. Likewise the more recent work on the physiology of the hypophysis is not considered and the author concludes that the functions of the hypophysis are not known.

Throughout the book the work of the Italian physiologists is perhaps naturally emphasized. The work of the German physiologists is necessarily given abundant consideration, but that of English and American physiologists, with the exception of Bayliss and Starling, is scarcely referred to. The work is well translated and is a valuable addition to the works on physiology available in the English.

Blood-Pressure from the Clinical Standpoint. By Francis Ashley Faught, M.D., Instructor in Medicine at the Medico-Chirurgical College, Philadelphia. Cloth. Price, $3 net. Pp. 281, with illustrations. Philadelphia: W. B. Saunders Company, 1913.

This book is written from the clinical standpoint. Comparatively little space is taken for the instruments and instrumental technic. The bulk of the work discusses the variations in blood-pressure and the conditions which cause them. The relations of blood-pressure to various diseases is discussed at considerable length. Therapeutics receives its full share of attention. The relative inefficiency of various drugs which have been heretofore relied on to increase the blood-pressure is clearly presented. The past generation of physicians were well convinced that digitalis, strychnin and several other drugs raised blood-pressure as part of their ordinary action. This is now disputed and a new attitude must be taken in regard to these old-time remedies. Similarly the older view that altitude raised the blood-pressure must give way to the results of observations which show that it produces little change, but that its influence is in the direction of depression rather than of elevation of the pressure. Full references are given as a rule so that the reader can pursue further studies on any part of the subject.

The People's Guide: Points for the Patient, Notes for the Nurse, Matter for the Medical Adviser, Succor for the Suffering, Precepts for the Public. By John Grimshaw, M.D., B.S., D.P.H. Cloth. Price, $3 net. Pp. 839. New York: The Macmillan Company, 1912.

It is recognized to-day that one of the functions of the medical man is the instruction of the laity. There is no better means for carrying out this function than by the popular medical guide or by some similar work designed to give the layman advice in regard to health. Such a work becomes a household oracle, consulted in the most serious emergencies. Such books in the past have often disgraced the medical profession by their crudities and inaccuracies. This is all the more reason why the modern writer should endeavor to redeem this field from the enemy represented by the nostrum man or the faddist. We believe that Dr. Grimshaw has endeavored to do this and has succeeded. The author has certainly given good measure and the volume is filled with valuable information and seems worthy of recommendation.

Calm Yourself. By George Lincoln Walton, M.D. Cloth. Price, $0.50. Pp. 46. Boston: Houghton, Mifflin Company, 1913.

This book is a plea for equanimity and a purely practical equanimity, such as will enable a person to take a street car in the rush hours without losing his temper. Not that the author expects any one to reach such a state, but he hopes that people will cultivate poise to the extent at least of lessening fears, of taking the edge off acute resentments against persons and things, of modifying impatience and curbing worry. As a shield against every-day annoyances the author advocates the use of the phrase "never touched me," and illustrates the way such maxims should be ready for immediate use by the following story in which the joke was *on him*: While the author was walking with a friend an automobile came up behind announcing its approach by a honk which was neither groan, grunt, growl, nor scream, but a mixture of all. He said to his friend: "Don't you hate these freak horns?" "I used to," said the friend, "but since reading your book I say to myself, '*never touched me*.'"

A Laboratory Guide to the Study of Parasitology. By W. B. Herms. Cloth. Price, $0.80 net. Pp. 72. New York: The Macmillan Company, 1913.

With the rapid growth of parasitology, especially in its relation to preventive medicine, there has arisen a demand for thorough laboratory instruction in this important field. The study of the methods of transmission of various parasitic and infectious diseases is of such vital importance to the country at large that every student, practitioner and, especially, every health officer should have at least a general knowledge of the characteristics and habits of the more common parasites and parasite-carriers. This guide comprises a series of practical laboratory exercises on the more common parasites. The exercises are admirably planned and should prove valuable in direct and differential diagnostic work.

Die Störungen des Verdauungsapparates als Ursache und Folge anderer Erkrankungen. Von Dr. Hans Herz. Second Edition. Part Two: Die akuten Infektionskrankheiten in ihren Beziehungen zum Verdauungsapparat. Paper. Price, 8 marks. Pp. 449. Berlin: S. Karger, 1913.

This is the second part of a monograph already described in The Journal. It will be as useful as the first portion. It embraces what is known of disturbances of digestion as causes or foci of entrance of causes of infections, and the disturbances of the digestive organs due to infectious diseases. The book will be found valuable by those especially interested in these subjects.

Hygiene and Sanitation. A Text-Book for Nurses. By George M. Price, M.D., Director of Investigation, New York State Factory Commission. Cloth. Price, $1.50 net. Pp. 236. Philadelphia: Lea & Febiger, 1913.

This book is designed to give the nurse a knowledge of the elements of hygiene in its various branches. Under "Hygiene of Habitations" there is perhaps a little more practical plumbing than the average nurse is likely to require in her daily work, unless, indeed, she is a member of the Visiting Nurses' Association, or in the employ of a city department of health. Taken all in all, however, the book is practical and should be of great value to all nurses, especially those engaged in work of a semipublic character, such as school nurses and health department nurses.

SYSTEMATIC CASE-TAKING. A Practical Guide to the Examination and Recording of Medical Cases. By Henry Lawrence McKisack, M.D., M.R.C.P., Physician to the Royal Victoria Hospital, Belfast. Cloth. Price, $1.50 net. Pp. 166. New York: Paul B. Hoeber, 1913.

The author has amplified the ordinary syllabus of case taking into a short manual which not only indicates the steps to be taken to elicit the desired information, but which discusses briefly the diagnostic significance of the various symptoms discovered.

LIPPINCOTT'S BLOOD-PRESSURE AND CLINICAL CHARTS. Designed by Percival Nicholson, M.D. Price, $0.50 per set of fifty sheets. Philadelphia: J. B. Lippincott Company, 1913.

This is a convenient ruled chart, designed to facilitate the plotting of curves of systolic and diastolic blood-pressure and temperature in Fahrenheit degrees. A single sheet will accommodate the records of three weeks.

Medicolegal

Lodge Physician's Contract and Right to Compensation

(Page vs. Cohen (N. Y.), 140 N. Y. Supp. 935)

[illegible] final [illegible]upreme Court of New York, Appellate Term, Second [illegible]ent, holds, in this action against the treasurer of C[illegible] by w[illegible] Island, No. 34, Foresters of America, that, the pla[illegible] been duly elected at the election of March 27, 190[illegible] [illegible]sician for a period of one year, this election con[illegible] [illegible]nployment, which being duly recorded by the [illegible] lodge proceedings, such record took the case out [illegible]ute of frauds requiring certain contracts to be in [illegible]e plaintiff protested over and over again that he [illegible]'s contract, which entitled him to 25 cents per me[illegible]e defendant lodge for the last quarter of the ye[illegible]iod in suit. Whether treated as an action for w[illegible]r breach of contract, the plaintiff on the case made was entitled to recover. There was no necessity for demanding that he elect on which ground he expected to recover. The period of his service having passed, and his compensation having been fixed by special contract, nothing remained to be ascertained except the number of members, on which his compensation was based, and his readiness and willingness to perform, his evidence of which was erroneously excluded.

When Silence Not Consent to Physical Examination

(State vs. Horton (Mo.), 153 S. W. R. 1051)

The Supreme Court of Missouri, Division No. 2, says that the defendant, who was convicted of rape, insisted that the physicians who examined him while he was in custody should not have been allowed to testify to the fact that he was suffering from a venereal disease. To meet this insistence, the state contended that the examination complained of was made with the defendant's consent. The court having read the record carefully, finds that the "consent" consisted of the failure of the defendant to object to the physical examination. When a man is under arrest, without counsel, and, speaking metaphorically, is standing in the shadow of a policeman's club, it requires something much more substantial than silence to justify an invasion of his constitutional right not to be compelled to furnish evidence against himself. If the evidence of the physicians had been objected to on the ground that the physical examination which they made under the orders of a police captain amounted to compelling him to testify against himself, as prohibited by Section 23, Article 2, of the Constitution of Missouri, then the admission of their evidence would undoubtedly have constituted reversible error. Instead of objecting to this evidence on proper grounds, however, the defendant merely objected because the physical examination took place after the preliminary examination before the committing magistrate. Such an objection was wholly insufficient to call the trial court's attention to the incompetency of this evidence.

Jurisdiction and Power of State Board of Health

(Board of Health of State of Louisiana vs. Susslin (La.), 61 So. R. 661)

The Supreme Court of Louisiana holds that Act 192 of 1898, of that state, as amended, confers on the State Board of Health jurisdiction over matters of local sanitation which, in the opinion of the board, cannot be efficiently and effectually regulated by the local boards. Act 98 of 1906 confers jurisdiction on the state board over the subject-matter of the manufacture, sale and inspection of foods within the state in so far as the same may affect the public health.

Such legislation is not repugnant to the provisions of Article 319 of the Constitution of 1898, guaranteeing to the electors of the city of New Orleans the right to elect their public officers charged with the exercise of the police powers and administration of the affairs of the city. Article 296 of the Constitution of 1898 vests in the general assembly the power to create state and local boards of health, and to define the duties and prescribe the powers thereof. This grant necessarily includes the power to determine the mode of the selection of members of boards of health, state and local, and withdraws the subject-matter from the purview of Article 319 of the same Constitution.

The preservation of the public health is a matter which concerns the state at large, and has been properly left to the State Board of Health, with jurisdiction to adopt a sanitary code of rules and regulations having the force of laws throughout the commonwealth.

The State Board of Health may enjoin the manufacture of food under such conditions as to render its use dangerous to the public health.

The court says that the point that the Board of Health, though armed with criminal remedies, may, in a proper case, have recourse to a civil proceeding or injunction for suppressing a public nuisance was definitely settled by this court in *Board vs. Maginnis Cotton Mills*, 46 La. Ann. 806, and, if one-half of what was alleged in the petition in this case as to the defendant's bakery being conducted in so insanitary a manner as to constitute a public nuisance was true, the case was a very highly proper one for such an injunction.

Constitutionality of State Pure Food Act Prohibiting Use of Boric Acid in Preservatives

(People vs. Price (Ill.), 101 N. E. R. 196)

The Supreme Court of Illinois holds constitutional the Illinois pure food statute enacted in 1907, and affirms a conviction of the defendant of violating it, he having been charged with having unlawfully manufactured for sale and sold a preservative compound known as Mrs. Price's Canning Compound, intended as a preservative of food, which was unwholesome and injurious in that it contained boric acid. The court says that the main purpose of the act is to protect health by preventing adulteration of food by any unwholesome and injurious ingredient. Boric acid is declared to be unwholesome and injurious, and the sale of any food to which it is an added ingredient is prohibited. It is just as important to prohibit the sale to the housewife of a compound containing boric acid, to be used by her to preserve fruits and vegetables put up by her for family use, as it is to prohibit the sale of fruits and vegetables after such an ingredient has been added. The reasonable construction of the act is that the prohibition against boric acid is not limited to foods to which it is an added ingredient, but extends to compounds, sold as a food preservative, which contain boric acid. The danger to health is as great from one as the other, and the prohibition of both was necessary to effect the evident purpose of the legislature. It may be conceded that the legislature has no authority to forbid the sale of a known wholesome article of food; but it is certain boric acid is not so universally conceded or known to be wholesome that judicial notice will be taken of it. Whether it is or not is a matter of dispute. In such cases, in enacting legislation in the exercise of the police power of the state, the legislative declaration that it is unwholesome must be accepted by the courts, and they will not investigate the facts for the purpose of determining whether or not the declaration of the legislature was warranted by the facts. Nor was the defendant protected, in the sale of the preservative, under the doctrine of the original package decisions of the Supreme Court of the United States, although the preservative in question was manufactured in another state and sold in Illinois in the original package.

Plaintiff Declared Barren, Afterward Giving Birth to Child

(Anshutz vs. Louisville Railway Co. (Ky.), 154 S. W. R. 13)

The Court of Appeals of Kentucky says that, in April, 1910, the plaintiff, a young married woman, aged 23, was injured while a passenger on one of the defendant's cars. At the time she was enceinte, and, September 6, there was born to her a boy baby. In April, 1911, she was taken to a hospital in Louisville, and, after having been there a few days, a serious operation was performed on her, at which time it was shown by the several physicians and surgeons who were present that there were removed from her body both fallopian tubes, the whole of the left ovary, and part of the right ovary. Her suit against the railway company for damages came on for trial on Dec. 21, 1911. Previous to the trial, however, the court, on motion of the railway company, appointed a surgeon to examine the plaintiff as to the nature and extent of her injuries, and her physical condition at that time. On the trial all the physicians and surgeons who were present at the operation in April, 1911, testified, as above indicated, with reference to the nature of the operation, and in addition that by reason thereof the plaintiff was made barren and could never have another child. They further stated that, at the time of the trial, a tumor had developed in her abdomen, which would sooner or later necessitate still another, and possibly more serious, operation, which would probably endanger her life. The surgeon appointed by the court, basing his testimony on the history of the case as given to him by the other physicians and surgeons, testified in substance to the same thing. The jury rendered a verdict for $7,000 for the plaintiff. On June 3, 1912, the plaintiff gave birth to another boy baby, and twenty-five days thereafter the railway company filed its action setting up this fact, and asked for a new trial of the former case, which was properly granted. There is nothing stronger in nature than the inherent desire to propagate one's species, and the fact that one has been wrongfully deprived of the procreative power would certainly, and must properly, appeal not only to the sympathy, but to the judgment of a jury, and incline them to be liberal in the assessment of damages. No reflection is intended on the physicians and surgeons who testified. Either there was some strange and unaccountable mistake, or one of those freakish things in nature happened which are so rare that they are said by scientific people to be impossible.

Climatic Observations at Davos.—Dorno has recently published the results of his observations at Davos, in which special attention was paid to the measurement of radiation, including separate records of the thermal, luminous, photographic and photo-electric intensity of direct radiation from the sun, and also the combined radiation from sun and sky, with and without clouds, etc. Discoveries have apparently been made which may have therapeutic applications. The most intense ultraviolet radiation occurs in summer, which probably explains the "glacier-burn" which occurs among patients in summer. A single summer day may give as much ultraviolet radiation as a whole month in winter. Thermal radiation, however, is most intense in the spring.—*Scientific American.*

Present Conception of Arthritis Deformans

Dr. David Silver, Pittsburgh: Infection is the usual exciting cause of joint diseases in general, although trauma may act as an exciting cause in individual joints. No form of arthritis is known to be due to metabolic disturbance, unless it be gout. In the more gradual types of onset, the resistance of the patient is not so good as in the acute form. Although infection is usually due to some definite local sepsis, recovery does not follow the removal of the probable source of infection. When the disease is once established, other causes become active in perpetuating it. Treatment, to be effective, must include not only the joint lesion, but also all the elements of the case: the removal of the infective focus, when found; the use of measures to bring about function as near to the normal as possible, and the local care of the joint. The problem frequently becomes one mainly of increasing the lowered physical resistance.

DISCUSSION

Dr. Gwilym G. Davis, Philadelphia: The infection in these cases may carry over a very long period of time, and may persist for years after the original focus has apparently been cured. In the early stages, the treatment should be directed against the infection, and in the later stages it should be a nursing treatment. Attention to the gastro-intestinal tract has certainly improved many cases.

Dr. George E. Pfahler, Philadelphia: One source of infection overlooked in such cases is the teeth. Even though one sees nothing locally, if the patient has had many fillings in the mouth or much dental work done I should advise that the teeth be thoroughly studied roentgenographically in the hope of finding the source of infection in obscure cases.

Dr. David Silver, Pittsburgh: We must not forget that pyorrhea and other common sources of infection may be secondary, and may be due to the debilitated condition of the patient.

Operative Treatment of Hernia

Dr. J. B. Carnett, Philadelphia: Practically all hernias of young children belong to the congenital inguinal or the infantile umbilical type. The great majority of these can be cured by nonoperative treatment. After one year of age this treatment becomes less certain and after five years cure seldom occurs. Femoral hernia is rare in children and is never cured by a truss. If truss treatment cannot be applied thoroughly, operation should be done. It is very exceptional for truss treatment to prove curative in the adult, and it should be used only in those who refuse operation or where it is contra-indicated. Incarceration and strangulation are frequent in truss wearers. Most trusses are of poor construction and ineffective. The only contra-indications to operation in adults are extreme old age, grave organic disease and very large, irreducible hernias. In strangulation taxis should be done only during the first four hours and must then be gentle. As a rule, it should not be done at all, but resort be had at once to operation, the earlier the better the results. As a rule Bassini's method of operation is the best, though it may be modified to meet special indications.

The Dental Aspect of Oral Sepsis

Dr. Randle C. Rosenberger, Philadelphia: The bacterial flora of an unclean mouth is very complex. Most of the organisms are nonpathogenic, but, when the enamel is injured, they produce erosion of the dentine and destruction of the teeth. The bacteria can be greatly reduced by proper attention to cleanliness. Decayed teeth and stumps swarm with bacteria which find their way through the dental canals and the dentine and produce diseases of the gums and the alveoli. Improperly capped teeth are a menace on account of the bacteria they barbor. One of the worst conditions of the mouth with which we have to deal is pyorrhea alveolaris, which is due to pus-producing organisms.

DISCUSSION

Dr. J. Harold Austin, Philadelphia: Certain obscure toxic conditions are undoubtedly due to oral sepsis. A difficulty is that of detecting these *foci* under certain circumstances. A patient with a streptococcic septicemia eventually developed an endocarditis with a fatal termination. The original focus of infection in that case remained quite obscure until shortly before death a superficial abscess in the lymph-nodes behind the angle of the jaw on the right side developed and at necropsy beneath the second lower molar was found a small abscess from which streptococci were isolated.

Dr. Joseph Head, Philadelphia: I have been treating pyorrhea alveolaris for ten years with moderately good results, but since using the autogenous vaccine and isolating every form of bacteria, we have better results and far more permanent. Also when the mouth cleared up the patients spoke of the great improvement they felt in the systemic condition, showing that there must have been a stopping of toxic material entering the blood which had reduced their vital forces. In the same way no one can hope to cure pyorrhea alveolaris when using vaccine without removing the source of infection.

Dr. I. Norman Broomell, Philadelphia: Oral sepsis is a potent factor favoring systemic disease. Such lesions are usually either directly or indirectly due to caries and this in turn is due to lack of oral hygiene. Prophylactic measures should begin early and extend to old age.

End-Results of Bone Tuberculosis

Drs. De Forest P. Willard and Frank D. Dickson, Philadelphia: Our observations are based on 200 cases very carefully selected in which the diagnosis was assured, the treatment thorough and the cases under observation at least five years. In 142 cases the disease is quiescent, forty-five are still under treatment and there have been thirteen deaths. Of the quiescent cases eighty have normal joint function and in sixty-two there is material impairment. Results have been much better when the treatment has been instituted early. The greatest benefit has been obtained by bed treatment as opposed to casts and braces. Strict enforcement of hygiene and supervision after leaving the hospital are essential.

DISCUSSION

Dr. W. J. Merrill, Philadelphia: I wish to emphasize two points: First, the absolute fixation of the diseased part until the disease is arrested and, second, the rest of the patient in bed during the acute stage of the tuberculous joint disease. Erroneous conclusions are often drawn from treatment of joint affections which resemble tuberculosis but are not tuberculous. Also, from the application and the faulty maintenance of bed and cast treatment. One fact is very evident, that the increase of good results is enormously enlarged by the introduction of early treatment.

Dr. G. G. Davis, Philadelphia: We must devote more attention to heliotherapy. That is, first, open-air treatment of tuberculous joints in the same way that you treat tuberculous disease of the lungs and, second, to expose locally the wounds directly to the sunlight. It is amazing to see in Switzerland children playing in the snow with nothing but a hat, a pair of slippers and apparently a breech belt.

Operative Treatment of Fractures

Dr. Edward Martin, Philadelphia: A further experience with the open treatment of fractures has brought conviction on certain points: To the effect that the fractures of children very rarely require outward intervention. In them reduction is usually easy and retention efficient. Moreover, even though reduction be imperfect, the tendency during growth is toward the correction of the deformity rather than toward an exclusion. This often is in marked contrast to the fractures of the adult, particularly to those at or past middle age. The bones during their growing period are more avid of nutriment than any other tissues of the body. It seems quite definitely shown that even with the most perfect apposition and retention by buried plates, supplemented by splinting, the healing of the fracture is slower than it is after satisfactory, though less perfect, apposition, without operative intervention. It seems clear that even with the most perfect technic and with primary healing, plates and screws at times become a source of irritation and must be removed. Time, skill and attention are devoted to reduction and retention and yet movement and massage, so important for restoration are too often postponed or omitted altogether. It is also clear that in fractures united with slight deformity this deformity in the case of the adult is often enormously increased by too early a use of the part. This is notably true in regard to fractures of the femur. By the Whitman reduction method and by the Phillip-Maxwell-Ruth double traction method it has been shown that fractures of the neck either subcapital or subtrochanteric, can, as a rule, be united and that good function will result. It is undoubtedly true that certain fractures of the femur cannot be reduced and cannot be retained. Such fractures undoubtedly should be subject to open operation. The best mechanical device for fixation after internal splinting, so far the best that none other can be mentioned beside it, is the vanadium steel plate of Sherman. This, with the screws and screw-driver supplemented by the use of the Lowman clamp and by an efficient drill, makes the operation of plating an easy one. The general principles where an open operation is needful for reduction, retention should be secured by the least possible amount of buried foreign material. Hence a strip of fascia and chromic catgut, strings, nails, screws, fine silk or wire are preferable to plates when they serve the purpose. Often they will not. There are some fractures, notably those of the tibia, in which union fails, though apposition is practically perfect, nor does metal plating help matters. Such fractures should be treated by either plating or pegging or otherwise bracing together with bone flaps taken from the patient at the time of operation.

DISCUSSION

Dr. William S. O. Sherman, Pittsburgh: The success in the operative treatment of fractures where plates and screws are used is dependent on three factors: First, an aseptic wound; second, screws which will not pull out, and third, a plate which will not break. Ninety-eight per cent. of the failures in this class of work have been due to infections, the pulling out of screws and the breaking of plates. The infections would be greatly minimized if the teaching and technic of Mr. Lane were carefully carried out. There is no occasion for the screws pulling out and plates breaking if the proper screws and plates are used. Why use three times as large if one-third will answer the purpose? Why use ten wood screws in a bone if two or four machine-made screws will have a greater holding power? Every mechanic knows that a wood screw should not be inserted in hard, compact bone. A mechanic would not put a screw in marble or ivory directly, he first drills the hole and then puts in his screw. In the last four years I have operated 150 times in a series of over 2,000 fractures. These cases were due to severe traumatism in the mills and mines in the western part of Pennsylvania. The end-results in these cases were very satisfactory; certainly the disability was greatly minimized. In the first series with Lane screws we found it necessary to remove 30 per cent. of the plates. Since using vanadium steel and tap screws only 2 per cent. of the plates have been removed.

Carcinoma of the Breast

Dr. John B Deaver, Philadelphia: Cancer of the breast is the type of malignant tumor analogous in its tendencies to internal cancer. The reason for this is that the patient is sent too late to the surgeon. The chief hope for reducing the mortality from cancer is to teach patients to avoid all sources of irritation, now regarded as causative of cancer, and to watch for early signs of malignant change. In our last 200 cases of cancer of the breast considered operable, an average of three years had elapsed between discovery of the lump and operation. Death occurred in more than 75 per cent. of the cases.

DISCUSSION

Dr. William L. Rodman, Philadelphia: The principal thought to be gathered from Dr. Deaver is that since we cannot certainly diagnose cancer in its early stages then the best thing to do is to operate in the precancerous conditions. I fully agree with him that perhaps every case of cancer of the breast is preceded by a chronic cystic mastitis. Statistics show that a percentage varying from 10 to 50 results in cancer. Therefore, the lesson to be drawn is not to wait for inoperable cancer. Until we have done that we will not achieve the good results in cancer of the breast we should.

The Transmutation of Tumors

Dr. William L. Estes, South Bethlehem: A number of surgeons have reported cases of tumors which have both epithelial and connective tissue malignancy. There are on record cases in which patients who have had cancer have developed sarcoma *in situ* or metastatically. I have seen several instances of this sort.

DISCUSSION

Dr. John Speese, Philadelphia: It is rather difficult to believe that in tumors, sarcomas or carcinomas, a transmutation can occur. It seems more rational to believe that these tumors are both independent, although we must admit with special pathology that long irritation by sarcoma may so stimulate the overlying epithelium that cancer may develop. Or, on the other hand, that as squamous carcinoma pushes down on the tissues the equilibrium may be so upset that sarcoma develops. They may occur side by side.

Inflammation of the Female Pelvis with Reference to Smears Made at Time of Operation to Determine the Necessity of Drainage

Dr. William H. Howell, Altoona: Ninety per cent. of diseases of the female pelvis are due to neisserian infection or to abortion. Gonorrhea is a mucous membrane disease and travels over the mucosa through the uterus to the tubes. Infections of the broad ligaments and Douglas' cul-de-sac are due to extension by way of the lymphatics. In such infections the treatment should be expectant until an abscess localizes the infection, when the pus should be evacuated per vaginam. In gonorrheal infection of the fallopian tubes the time favorable for operation should be awaited, when salpingectomy should be done. No conservative operation will ever restore the function of the tube.

DISCUSSION

Dr. Brooke M. Anspach, Philadelphia: Unquestionably in pelvic surgery the best treatment is non-operative during the acute stage. That is almost invariably true in the cases of gonorrheal pelvic infection, and the surgeon does well who leaves these cases alone until the conflagration has subsided and until the results of the destructive lesion are apparent and the virulence of the infection has passed, and when he will need to do less radical surgery than during the acute stage. The same conservative plan is advisable in puerperal infection, which is usually of a much more serious type. Under these circumstances if the infection can be reached by a vaginal or an extraperitoneal incision, that of course is the procedure of choice and in the great number of cases proves a life-saving measure. If it cannot be reached by this means and we are obliged to do an abdominal operation, then, I think, drainage must be a part of the technic.

Dr. George M. Boyd, Philadelphia: We are getting away from the early surgery of obstetric infections. We must look on the early puerperal infection as a general infection and not a local infection. The question also arises whether the patient has developed on top of her puerperal infection a gonococcus infection. I invariably say that if it is a simple puerperal infection in all probability the trouble would have disappeared within two or three months, but in gonococcus infection a mass can be felt months after the delivery.

Dr. G. E. Shoemaker, Philadelphia: I want to endorse what Dr. Howell said about the effectiveness of the waiting method in the handling of the puerperal infections and the danger of operating in all these cases through the abdomen in the active stage. The particular point he raised as to the method of getting help from microscopic examination is limited to a very few cases.

Some Diagnostic Errors in Differentiating Lesions of the Cervix

Dr. Edward Weiss, Pittsburgh: In case of lesion of the cervix uteri one should always think of cancer. The early symptoms of cancer of the cervix are not characteristic. If examination is refused by the patient, no treatment should be given, but the dangers of indiscriminate drugging and douching explained to the patient. Too often the mistake is made of waiting for positive signs. Any ulcer-like lesion of the cervix should be referred to an expert for diagnosis if it does not respond quickly to local treatment. It is very difficult to make a diagnosis from sections. I have recently encountered five errors made in this way. One of the most confusing conditions is cystic degeneration of the nabothian follicles. Ulceration from procidentia or chancroids is sometimes mistaken for cancer. Every married woman above forty years of age should be urged to submit to examination once or twice a year.

DISCUSSION

Dr. G. E. Shoemaker, Philadelphia: One of the sources of error and subsequent sorrow is the dependence on symptoms both on the part of the patient and on the part of the physician. We cannot wait for the development of pain or odor, or emaciation. We frequently see the stout, healthy-looking woman with advanced carcinoma.

Dr. John A. McGlinn, Philadelphia: Many women have symptoms which undoubtedly point to cancer of the cervix and never consult the family physician until it is too late to do anything for them. So that, while I believe it is of great benefit to teach the general practitioner the necessity of early diagnosis, we should teach the women to have frequent examinations when they have any symptoms referable to the genital tract. I believe the early diagnosis of cancer is practically valueless unless this diagnosis be made by microscopic examination of the tissue. I believe we are wasting time in teaching the value of early diagnosis and not teaching that the time to operate on cancer of the cervix is before the patient has cancer of the cervix.

The Roentgenogram in the Diagnosis of Gastroenteroptosis

Dr. Henry K. Pancoast, Philadelphia: The diagnosis of gastroptosis can usually readily be made clinically. The real value of the roentgenologist is to be found in the deduction of a comprehensive knowledge of the condition and all the factors concerned, some of which can be obtained in no other way. There are, however, many chances of error. According to our present knowledge the greater curvature of the stomach may extend to or even two- or three inches below the navel without impairment of its function. Gastroptosis is now known to be much less frequent than formerly supposed. The mistake is often made of ascribing digestive and neurasthenic symptoms to gastroptosis when these symptoms are due to other causes. In the Roentgen rays we have the best method of determining gastric motility and atony. Severity of symptoms and failure to relieve them by other means, rather than the roentgenographic finding alone, furnish the indication for operation, though the Roentgen rays enable the surgeon to decide on the type of operation and whether it is likely to give relief or not; also to learn the anatomic results of operation.

DISCUSSION

Dr. David Silver, Pittsburgh: I would like to emphasize one point in treatment, the importance of teaching the patient the importance of voluntary abdominal control. We can give them corsets and exercises to increase the strength of the muscular wall, but, if we do not teach them control, we will fail of our object. Unless we change the posture and restore the normal contour, how can we expect a simple fibrous band to hold up an organ after the ordinary pursuits of life have begun again?

Dr. **Joseph Sailer**, Philadelphia: I think that the reason for the divergent views held by physicians and surgeons in reference to splanchnoptosis is that it is neither a medical nor a surgical subject in itself. It belongs to both departments. The services of a physician in the diagnosis are perhaps equally as important as the services of a surgeon for cure. Whether the surgeon or physician supervise the treatment our methods of cure are what we commonly call external therapeutics. They consist of exercise, support and posture and to a very slight degree the application of drugs. It makes very little difference to the patient, and it ought to make very little difference to the physician, what position the colon assumes in the abdomen, providing its function is performed. It makes very little difference what is the position of the greater curvature and pylorus if it furnishes secretion and provides nutrition for the body and gives no definite symptoms. I believe that in the treatment of these cases a great deal is accomplished by means of breathing exercises and abdominal support.

MEDICAL ASSOCIATION OF THE SOUTHWEST

Eighth Annual Meeting, held at Kansas City, Mo., Oct. 7-8, 1913

The President, Dr. **W. T. Wooton**, Hot Springs, Ark., in the Chair

Prophylaxis of Syphilis and Professional Ethics

Dr. **Alfred Schalek**, Omaha: Syphilis must be attacked in two directions: in its relation to society and to the individual. Prostitution contributes the greatest factor in spreading infection. It is only a question of time before every prostitute becomes diseased. Official regulation has proven a failure wherever attempted. Absolute suppression is the only relief. While seemingly an utopian dream, it is feasible with the honest cooperation of everybody concerned. It necessitates measures to stop all sources leading to prostitution. When the time comes that syphilis is looked on only as a pathologic condition, in no way different from others, when its stigma of disrepute has been removed, when our therapy will destroy the micro-organisms and eliminate the toxins, and not only secure a symptomatic but real cure, our ambition to make syphilis a disease of the past will begin to be realized.

DISCUSSION

Dr. **William Frick**, Kansas City, Mo.: I wish to emphasize the fact that a great many cases of syphilis are innocently contracted. I recall the case of a young woman who developed a chancre of the upper lip. She was having her teeth repaired and injury was done to the upper lip. In about the proper length of time a chancre developed. She had a secondary eruption.

Dr. **J. D. Kernodle**, Boyle, Okla.: I believe ignorance is at the bottom of the trouble. There is not a boy or girl who does not know right from wrong, but they do not know the tremendous consequences following a wrong. They need education along these lines.

Dr. **E. H. Martin**, Hot Springs, Ark: If you admit you can cure syphilis, you will admit that the best method is prophylaxis.

Dr. **R. H. T. Mann**, Texarkana: Is it possible to eradicate syphilis from America? It is, but it can be done only when the medical profession awakens to its full responsibility and gets the assistance of the various communities and state governments. Whether this task can be performed in this generation, or whether it will fall on future generations to drive syphilis out of America, depends wholly on the activities of the physicians now living, but it is a task that can be accomplished. The medical profession owes it to humanity to eradicate syphilis from this country.

Dr. **E. G. Mark**, Kansas City, Mo.: With regard to the prevention of venereal disease, we must take the stand as physicians that prostitution cannot be eradicated, but you can segregate and control it. With proper segregation, proper inspection, venereal diseases can almost be eradicated, but prostitution can never be suppressed.

Dr. **Ross Grossheart**, Tulsa, Okla.: Venereal diseases and their dangers should be taught to the pupils of high schools, and when this is done sexual evils will be lessened and much done toward the wiping out of syphilis.

Surgical Constipation

Dr. **A. L. Blesh**, Oklahoma City: Aside from various stenoses, congenital or acquired, constipation has principally to do with the colon, or to better express my meaning, the colon has most to do with constipation. Coprostasis is the *fons et origo* of a train of pathologic sequences ranging from the misnamed "biliousness" to true organic nephritis and other organic degenerations which have long been treated as entities. The field of so-called idiopathic or purely functional constipation is becoming more and more circumscribed, and more and more we are coming to realize that mechanical interference is at the bottom of the condition. These mechanical causative factors frequently consist in embryologic deviations having their origin in evolutionary processes, that is, reversions to some remote ancestral type. Many of these deviations exist without symptoms being fully compensated in one or more of several ways. They may exist symptomless for a time and then be brought to the surface by some grave physical crisis, such as reducing illness, and especially so by labor in which hitherto compensating elasticity of a tense abdominal wall is lost by overstretching. That compensation, when it consists in muscular overdevelopment of the colon itself, may be lost, as is the case with any other overmuscularization of a hollow viscus. I have anchored the colon in eight cases, with complete relief of constipation and sequences in four; partially relieved, two; unimproved, two; ileosigmoidoscopy with separation of ileum, five; completely relieved, three; improved, two; cecosigmoidoscopy, two; completely relieved, two; Lane short-circuiting, severing of the ileum with implantation low in the sigmoid, in three; all are much improved, but all have had attacks due to regurgitation mentioned above.

Operative Treatment of Constipation

Dr. **W. J. Frick**, Kansas City, Mo.: Operative treatment of constipation is indicated when some degree of organic obstruction of the intestine exists. I am not an advocate of surgical interference in this condition, except after all intelligent efforts at a medical cure have failed and the patient is threatened with a permanent invalidism. Concerning the bands, membranes, adhesions and kinks, we cannot yet be certain whether they are the cause or the result of constipation. According to the available evidence, it would seem that they were the cause rather than the result, since the most recent researches appear to support the theory that they are developmental in origin rather than the result of inflammatory processes. But that they may bear neither causal nor resultant relationship to constipation is shown by the clinical experience of competent observers. Certainly much improvement follows the division of these structures in some cases; just as certainly this treatment has given not the slightest benefit in other cases. Another of the causes of constipation is the result of chronic pelvic peritonitis. I have in mind the fixation of the pelvic colon to the pelvic floor or to the rectum.

Some fibroids of the uterus, retrodisplacements of uterus and tense cysts are capable of exerting such pressure on the pelvic colon as to cause difficult, painful and inefficient defecation. After removal of the tumor or correction of the displacement, these patients recover from their constipation. Among other short-circuiting operations is one done for exclusion of the splenic flexure, that is, anastomosis between the ascending limb of the transverse colon and the decending colon. Colectomy relieves all the trouble that may have existed in the colon; however, the removal of the colon is a formidable operation and is not without danger. It is not an operation for one who has not had a large experience in abdominal surgery. All short-circuiting operations of whatever type are contra-indicated in cases in which the cause of the trouble lies distal to the lower portion of the pelvic colon. In such cases ileosigmoidostomy cannot relieve, but, on the contrary, may even aggravate the trouble.

Uncinariasis in the Middle States

DR. ESTILL D. HOLLAND, Hot Springs, Ark.: The treatment of hookworm is not as simple, safe or satisfactory as you may have been led to believe, but if you can start treating a patient who has two hundred hookworms and even get half of them with each course of thymol, it will not be long before he will either be cured or else have so few remaining that they will not cause him any inconvenience—provided he does not get a reinfection. The examination of the stool of patients will explain a great many chronic cases. There is no way to diagnose a moderately severe case of hookworm except by examining the stool, and if a patient has the disease it will practically always show on such an examination.

The High Short Incision for Cesarean Section

DR. H. S. CROSSEN, St. Louis, Mo.: The high incision in suitable cases has two distinct advantages. First, there is less extensive handling of the peritoneal surfaces—hence less peritoneal shock and less danger of infection from handling. Second, the incised uterus drops away from the abdominal incision, thus preventing adhesion and firm fixation of the incised uterus to the abdominal wall, which has proved a serious matter in some cases operated on by the usual incision. Of course, the high incision is suitable only for clean cases, where it is permissible to open the uterus within the peritoneal cavity. When the uterus is infected, the long incision should be used so that the uterus may be turned out before being opened. Again, when there is a probability that the uterus will have to be removed, on account of a tumor or other complication, the low incision should be employed. In the majority of clean cases requiring the cesarean section, the high incision will be found decidedly advantageous.

A Study of Epilepsy Based on One Thousand Admissions to the Kansas State Hospital for Epileptics

DR. M. L. PERRY, Parsons, Kan.: To be effective, systematic treatment should be begun early in the course of the disease and must be long continued. There are few diseases in which individual treatment is so important. Every case of epilepsy presents distinctive features which have a bearing on its proper and scientific handling. A very large number of patients will show temporary improvement under a change of treatment. In all head injuries a careful examination should be made for fractures of the skull and for evidence of depressed bone or meningeal hemorrhage. Any of these conditions call for immediate operation as a prophylactic measure. In all cases jacksonian epilepsy should be operated on if seen early. In long-standing cases due to cortical irritation and in chronic epilepsy from other causes little may be expected from intracranial surgery. As a routine measure, a search should be made for peripheral irritations to the nervous system and if any are found appropriate remedies, either surgical or medical, should be instituted for their relief. The attention should not be too strongly concentrated on merely checking the convulsive attacks, but it should be borne in mind that they are only symptoms of a general nervous disease. There is no drug which of itself will effect a cure. Of all the drugs used in the treatment of epilepsy the bromin preparations are the most effective. The bromid of sodium is the most satisfactory, as a rule. There is no advantage to be gained by combining a number of the bromids. Comparatively small doses of bromids usually yield better results than do large ones. Bromids should never be given, except in proper doses determined for the individual case and when the patient is under the frequent observation of a physician. I am convinced that most of the disrepute into which the bromids have fallen in recent years is directly due to their indiscriminate and unscientific administration. Any form of medical treatment will be limited in its effectiveness unless reinforced by hygienic and dietetic regulations.

(To be continued)

MINNESOTA STATE MEDICAL ASSOCIATION

Annual Meeting, held at Minneapolis, Oct. 2-3, 1913

The President, DR. R. J. HILL, Minneapolis, in the Chair

Common Infections That Are Often Erroneously Diagnosed as Grip

DR. C. L. SHERMAN, Luverne: During the first four months of this year a number of cases of influenza developed in Luverne and vicinity. I attempted to study fourteen cases. Smears from the throat, sputum and secondary lesions were examined and cultures made. The influenza bacillus was found in only two. Streptococci were present in all cases, often in pure culture. In many respects they resembled the organism described by Davis and Rosenow. The pneumococci were present in four cases, and, in one instance, though not suspected previous to the examination, the tubercle bacillus was found. The onset was invariably abrupt. Fever was present in all cases, ranging from 101 to 104 F. Well-marked symptoms of infection of the upper passages were constant. All the patients complained more or less of sore throat. Cough, present at the time of the attack or developing within forty-eight hours with more or less expectoration, prevailed in all cases. Twelve had headache. Thirteen complained of pain in the back and limbs. Nervous symptoms were marked in six. Prostration and a feeling of disagreeableness out of proportion to the other symptoms usually prevailed. In one case in which the influenza bacillus was found there was no complaint of headache or pain. In the two cases in which the influenza bacillus was present the organism was found in smears from sputum and throat as well as in culture. Two had acute suppuration of the middle ear following the acute attack. Pure cultures of streptococci from the pus were obtained in both cases. One patient developed empyema. Pure cultures of streptococci were obtained from the exudate. One developed acute arthritis of both ankles. I feel justified in venturing the assertion that the majority of localized outbreaks considered by physicians as influenza are not caused by the influenza bacillus and should therefore not be designated as influenza.

DISCUSSION

DR. C. C. PRATT, Mankato: I would like to ask Dr. Sherman if in these cases in which he demonstrated a pure culture of the streptococcus, whether the streptococci appeared in chains when he made merely smears as well as the cultures? I find oftentimes that I get a diplococcus that appears to be a pneumococcus on smearing, but in culture it runs out in chains.

DR. C. L. SHERMAN: In answer to Dr. Pratt's question, I will say these streptococci did not occur in chains invariably, but the chains were shorter than the chains usually found in suppurative inflammations.

Preparatory and Postoperative Treatment

DR. FREDERIC J. PLONDKE, St. Paul: When circumstances permit the patient should be placed on a restricted diet for two or three days before operation. This should consist of well-cooked, easily digested food, low in proteins and devoid of raw fruit and vegetables, with a large quantity of water. From thirty-six to twenty-four hours before the operation she should receive a nonirritating cathartic, preferably castor oil, one or two ounces, and two or three hours before soapsuds or a simple enema.

In emergencies, where time does not permit a movement from a cathartic at least six hours before the time for operation, one had better rely on the enema alone, as a churned-up condition of the small intestine at the time of operation is not conducive to a comfortable postoperative convalescence. Every effort should be made to allay the fears of the patient, no matter how grave the prognosis.

When a patient's preoperation record and her general condition at the time for operation are such as would indicate a possibility of shock developing, we give a hypodermoclysis of normal salt solution as soon as she is partially anesthetized and before the operation is begun, allowing the solution to enter slowly during the time the operation is in progress, giving about three pints in all. If, in the course of an apparently simple operation, it is found that for any reason it might be unduly prolonged, the hypodermoclysis is begun at once. Under no circumstances do we wait until the pulse indicates impending shock. The salt solution is given during the operation in all septic cases, not for the stimulating effect alone, but also for the purpose of diluting the toxins. When the operation is sufficiently advanced that a distended colon does not interfere, she is given one quart of salt solution per rectum. This is done while she is sound asleep, otherwise it might be expelled. In the septic cases, and where the operation has been prolonged, proctoclysis by the drop method is begun one and a half hour after leaving the table. For this purpose one-half strength salt solution or tap water is employed. These preventive measures have been used by us for the last two years with the result that in over one thousand operations during that time there has not been a single case of severe shock.

In acute dilatation of the stomach following an operation gastric lavage usually gives prompt relief. Postoperative pneumonia is usually the result of preexisting bronchitis, careless exposure or inhalation of foreign particles, while the patient is unconscious. The treatment is largely preventive. With the use of salt solution during and after operation, thirst has lost most of its terror. Where formerly fluids were withheld entirely or allowed only in sips, there is now no hesitancy in giving them in liberal amounts.

DISCUSSION

Dr. J. W. Little, Minneapolis: In our practice, if a patient comes into the hospital on the day of operation we make no preparation aside from giving an enema a few hours before operation, but if the operation is done very soon no enema is given. Nothing is given until the patient is brought into the operating-room, and the skin has been cleansed with iodin, half strength. We dilute the iodin with alcohol. Benzoin is applied to remove any oil on the skin before that. In old people we give very little cathartics—in fact, not any at all the evening before, otherwise we usually give an ounce of castor oil, followed in the morning by an enema.

Dr. J. W. Andrews, Mankato: As to the preparation of the patient with the use of antiseptics, iodin and other agents before operation, I believe the majority of practitioners depend on iodin. There is great danger in administering morphin in cases of gas pains, for the reason that while it may relieve for an hour or two, it is all the time aggravating the condition, and I have seen a fatal issue from the use of morphin. If it had been withheld the patient might have recovered. I have seen cases of intestinal obstruction caused by morphin; the distended intestines were unable to perform their function. The hypodermic use of eserin is excellent, but in small doses only. One-thirtieth grain of physostigmin is a powerful remedy. I have seen one death from it. Death occurs on account of the arrest of respiration.

Dr. W. H. Aurand, Minneapolis: I would emphasize the importance of examining the patient's blood before operation and the condition of the kidney. Oftentimes we are too hasty in going into operations that should be postponed. We can prepare our patients for a month in advance, getting them in proper condition to stand a serious operation.

Dr. W. H. Magie, Duluth: In my experience the gastric disturbances are proportionate to the amount of ether that has been given and the traumatism and exposure of the abdominal contents. If one is sufficiently dextrous so that he can do an appendix operation in ten or fifteen minutes, gastric disturbances are not so likely to follow the operative procedure. There is very little need of morphin.

Dr. Donald Balfour, Rochester: I would like to emphasize the value of enterostomy in cases of obstruction. There is no doubt that by bringing up a loop of distended bowel in all cases of impending obstruction, or when it is evident from the patient's condition and a gradually increasing trouble that this obstruction is not going to be relieved, the performance of enterostomy will save many lives that would otherwise be lost.

Dr. J. Bacon, St. Paul: It would be folly to depend on morphin to relieve pain without trying to relieve the condition which produced it. But in the early stages after abdominal operation, pain is usually due to excessive peristaltic action. If we refrain from the use of morphin we exhaust our patients or allow them to become so. One other point: we know that the use of salines lessens the function of the kidney. For the past year I have been using plain sterile warm water in these cases. The patient retains readily far larger quantities of this liquid than of salines. The kidneys functionate early and more readily.

Dr. C. J. Holman, Mankato: With reference to acute dilatation of the stomach, if, in addition to the use of gastric lavage, you will place the patient on the abdomen to the right, you will find that the cause for obstruction at the pyloric end will be removed, and the patient will rest a great deal more comfortably and will not continue to have acute dilatation. I have been using plain water for the last six or nine months, and find my patients are more comfortable.

Dr. R. E. Farr, Minneapolis: In my experience we not infrequently have shock in some of our bad cases, and anything that can be used to prevent it is very important. The work of Crile shows that the prophylaxis with regard to shock is important, and I believe the time is coming when it will be a universal procedure to cut down the amount of anesthesia as he has done, thus reducing not only shock perceptibly, but the mortality and morbidity.

Accident Neurosis

Dr. J. M. Lewis, Minneapolis: The type of neurosis I wish to consider is the result of accident without lesion or with such structural damage that repair should follow without loss or disturbance of function of the injured part. Deformities caused by hysterical contractions closely resemble those caused by traumatism. The character of the accident, the amount of force and how applied, and the immediate effects of the injury should be considered carefully. The remote development of symptoms out of proportion to the immediate is always suspicious; that causes other than those from accidental injury are in evidence. Simulation is difficult and usually easily detected. Exaggeration is always a factor in personal injury claims. Subjective symptoms are unreliable and must not be accepted unless sustained by other evidence than the individual's statement. In these cases we have to deal with a condition. What is to be done with the victim who is really incapacitated by the conspiracy? The courts have held that liability is just as great for the accidental death or injury of a person diseased as one in health, and I believe that the lawyer and the doctor who frame up these fake injury cases should be held responsible when a claimant becomes disabled from the effects of this type of accident neurosis.

DISCUSSION

Dr. A. A. Law, Minneapolis: When we stop to consider that every man, woman and child in the community is educated by the lay press, by unscrupulous doctors, and by still more unscrupulous lawyers, that they can recover damages from corporations, is it any wonder they magnify their symptoms? Every one of us is familiar with case after case where people have symptoms out of all proportion to the injury, symptoms which are subjective, pure and simple, and the very minute they get a verdict or have a settlement made they throw away their crutches. Therefore, our skepticism.

The Interrelationship of High Blood-Pressure and Renal Disease

Dr. E. L. Tuohy, Duluth: We may arbitrarily speak of three groups: 1. This group comprises those individuals with so-called hypertension, varying pressure going up to 170. A patient in this group probably needs his life, work, diet, and habits corrected. 2. Where the pressures register from 165 to 185, and are inclined to remain there, we may infer that there is a general arteriosclerosis, in which the kidneys are taking part. A sclerosis of the splanchnic vessels may be responsible for this extra rise of 15 to 20 points, instead of the kidneys, but splanchnic sclerosis is very infrequent. 3. This group with the systolic pressures persisting above 185, and the higher they go, the more definite they become, we may look unerringly to a true nephritis as their source. Careful observation of the urine and the amount passed in twenty-four hours will show us the signs confirmatory of chronic interstitial nephritis.

Meddlesome and misapplied therapy in the first two groups can do little harm. In the third it can work great havoc. It should never be forgotten that the high blood-pressure is Nature's method of retaining compensation. This does not mean that there is no therapy. A determination of the cause of the nephritis in the beginning should theoretically stay its course. If found in its full development, with restriction of the fluids taken into the body and the proper ordering of the patient's life, coupled with the reduction of the blood-pressure within moderate limits, immense relief from many symptoms is afforded, more particularly those of a nervous nature. Undue lowering of the pressure invites uremia. If he is in the stage of decompensation, his condition is by no means hopeless. The resources shown by Nature in carrying him so far as she has still attend him, and a little conservative assistance on the part of the physician may greatly extend his allottment of years.

DISCUSSION

DR. GEORGE DOUGLAS HEAD, Minneapolis: What is the cause of hypertension in nephritis? It is not caused by thick rigid arterial walls, since many cases of nephritis with high tension have elastic, pliable arteries. Furthermore, thick, pipe-stem arteries do not always mean high arterial tension. The toxic substances which a damaged kidney fails to excrete do not of themselves cause high blood-pressure. In many cases of acute nephritis, with scanty urine and diminished excretion of solids and fluids, the blood-pressure is normal or below normal. In my experience, acute nephritis is not often accompanied by an increase of blood-pressure. Extensive glomerular disease has very little to do with high blood-pressure, since in most cases of waxy kidney, very little, if any, increase of blood-pressure and almost no cardiac hypertrophy are encountered. Bright in his original study of nephritis suggested that the altered composition of the blood, due to a failure of the kidneys to eliminate waste product, thus bringing on a vasomotor spasm of arteries and arterioles, was the cause of hypertension and hypertrophy of the heart. Experimental evidence is not lacking to support this view.

The Importance of Orthopedic Treatment in Tuberculous Joints, Based on Twenty-Five Years' Experience in Four Thousand and Ten Cases

DR. ARTHUR J. GILLETTE, St. Paul: Some years ago absolute rest in bed for months and even years was advocated, but the results obtained were not any better than those obtained in cases which were allowed what we might now call "graded labor." In cases where the limb is perfectly straight a brace can be applied which will hold it so that the patient has no pain or temperature, or if there is a deformity which can be adjusted so as to overcome the deformity as much as possible gradually, and when overcome will allow the patient to be up and about, the more he is out of doors the better. Tuberculous diseases of the joints are benefited by fresh air just as much as tuberculosis of the lungs, and exercise is also beneficial as long as it is not carried to the point of exhaustion. If a patient has a temperature after being up and about, if no other cause can be found to account for it, he should be put to bed and should remain there as long as he continues to have a temperature above 99 F. Children or adults should not be allowed to consider themselves as invalids. Children should go to school and play, and adults should do some work suitable to their condition. Medical treatment is of the greatest importance. If a patient is anemic he should have iron, and if fleshy, beechwood creosote. Oils and fats are also very important for the thin cases. The use of cod-liver oil has been practically abandoned by us because very few children can take it. They will take butter, eggs, milk, beef and meat juices. If we will only keep in mind that the orthopedic treatment simply prevents deformity and pain, and is of immense importance in this way, and that a tuberculous disease of the joints is only a local manifestation of a constitutional disease, and while we are treating the joint do not forget that it is attached to a human being whose constitution needs building up, if you expect local improvement, then we will be treating tuberculosis of the bones and joints as it should be treated by an orthopedic surgeon.

6. **Treatment of Structural Scoliosis.**—As the result of his experience with Abbott's method Freiberg believes that it is possible to secure the reversal of the elements of deformity in some of the cases of structural deformity by Abbott's method. It appears that in quite a number of cases the means of correction cannot be exhausted in one jacket. Freiberg thinks it is probably better to remove the original jacket at the end of six weeks to ascertain what further needs to be done and what can be done. It is Freiberg's conviction that this method of applying corrective jackets constitutes a great advance and that the correction which we do secure is much greater than we have obtained by former methods. Whatever discomfort is involved is usually justified by increased efficiency.

8. **Fixed Types of Lateral Curvature.**—Keeping Abbott's cardinal principle before him, that is, to thoroughly flex the spine in applying the jacket, Meisenbach added somewhat more felt than ordinarily to the posterior part of the spine, with the hope of obtaining more flexion and gradual pressure later on. To obtain this, a window is also cut over the point of most pressure, and a steel trap-door so arranged that additional felt may be added at will and pressure applied with a wrench. This has permitted four or five thicknesses of felt, whereas one or two only could have been used by the other method of attempting to add felt to the window. The pressure then can be gradually added and correction obtained some weeks after the corrective jacket has been applied. By

this method, the pulse and blood-pressure can be followed thoroughly, and if there is too much pressure, less be applied. It also has the advantage that in cases of sloughs they can be dressed and the pads so arranged as to avoid pressure over them.

Meisenbach emphasizes that it is surprising to see how small a change of blood-pressure takes place when the rotary force and flexion are applied. Patients troubled by ptosis and gastric symptoms may improve in general health with a disappearance of symptoms after the spine has been corrected. The hemoglobin may often increase its percentage after the spine has been corrected, and without medication. Meisenbach would not make it the rule to attempt to build patients up by medication, and thereby lose time in spinal correction, but after the spine is corrected, he says, these measures may be undertaken with better success. Cardiac lesions, especially functional, due to pressure, may improve after correction, and are not increased. In cases of the severest types with great deformity of spine and derangement of viscera, treatment should be undertaken cautiously, with a view of improving the general condition of the patient.

11. **Rotation Treatment of Scoliosis.**—Forbes' rotation treatment of scoliosis aims at causing the correction of the deformity by the production of its counterpart. The production of physiologic scoliosis of an opposite character to the pathologic scoliosis which already exists is undertaken by rotating the patient's thorax on a fixed pelvis in a direction toward the side of the convexity of the curve. In thus producing physiologic scoliosis of an opposite character to the pathologic scoliosis from which the patient suffers, he not only changes the curve of the spinal column but also changes the deformity of the thoracic walls; that side which bulges unduly is flattened, and the flattened side is filled out. Forbes again describes his method in detail.

25. **Study of Water of Lake Michigan.**—As a result of their studies, the authors state that the water of Lake Michigan along the Wisconsin shore is not a uniformly safe source of supply. The water is polluted and at times quite heavily so, even out to a distance of seven miles from shore. The chemical and bacteriologic data conclusively indicate that there are no permanent currents in this portion of the lake, and that sewage once deposited in it may be carried to various points, depending on the direction and force of the wind. The prevailing currents cannot be depended on to insure safety, owing to storms, and even winds of moderate force which continue for several days will modify these currents. Even in those instances in which ledges of rock are supposed to form a barrier, safety is not insured. They conclude that to insure a safe supply from the lake, the intake should be carried out twelve to fifteen miles from shore. Owing to the depth of the water this is in many cases impractical and involves great expense. There are only two other procedures left open. One is the purification of sewage, which would be only a partial remedy, and the other is the filtration of the water before carrying it into city mains. In any case it seems that cities should cease the pollution of the lake by the dumping of their sewage into it.

This does not entirely meet all the requirements in the case, owing to the enormous amount of shipping on the lakes. Thousands of passengers on steamships are discharging their excreta daily during the larger part of the year into the water along the shore, especially in and about harbors. It seems probable that in spite of sewage purification, which should be undertaken in any event, that the demand for filtration will increase yearly, and that eventually all these cities will be obliged to furnish filtered water to their inhabitants. In the meantime, the use of hypochlorite of calcium has been recommended, and used in a number of instances with the most satisfactory results. This must always, however, be regarded as only a temporary expedient. The Great Lakes must still be looked on as a most useful and inexhaustible source of supply, but more care must be exercised in the future in preserving their purity and in selecting the locations for water-supply plants.

34 Case [illegible] Thoracis Treated by Successive Rib [illegible] New York.

28. **Vulvovaginitis in Children.**—In Barnett's series of twenty-six cases the following complications were present: arthritis of the shoulder, 1; arthritis of the wrist, 1; chronic general peritonitis, 1; pelvic peritonitis, 2, and painful heel, 1. The patient in the latter case was 11 years old and a roentgenogram showed a periosteal exostosis. Burning sensation on urination occurred in 30 per cent. of the cases. The irrigating solutions Barnett has used were potassium permanganate, 1-1,000; bichlorid of mercury, 1-4,000; Lugol's solution of iodin, 1-500. For instillations 1 or 2 grams of nitrate of silver ¼ per cent. and argyrol 10 per cent., were injected through a small catheter and retained three to five minutes. A cotton applicator saturated with nitrate of silver, 10 per cent., was also used to swab the vaginal wall.

Fourteen girls were treated with vaccines at intervals of three to seven days in doses of from five to one hundred millions. The injections were generally made in the buttocks. Each of the above methods received a most painstaking trial, and Barnett has finally adopted the following mode of treatment: The mother is instructed at the clinic in the method of giving the vaginal douche and in preparing the permanganate solution, 1-10,000 or thereabouts. This injection is to be given in the homes daily. The patient is put on small daily doses of hexamethylenamin. In the clinic the patient is treated with the electric endoscope. The child is placed on the bed-pan in the dorsal position, the foot of the table being raised to an angle of 30 degrees.

As to the complications, both cases of arthritis showed rapid improvement with complete cure of the arthritis following the use of vaccines, but the vaginal discharge did not diminish in either case, and the vaccine treatment was therefore suspended in both cases. In both cases of pelvic peritonitis treatment was suspended for an indefinite period. No vaccines were given in these cases. The painful heel was improved by the vaccine treatment, but at times there was a recurrence of severe pain at varying intervals. Of the twenty-six cases studied only seven were cured at the end of six months by irrigation alone. Seven of these cases after irrigation had failed have been treated with the endoscope, and five of these were cured in one month. Five additional cases of the twenty-six which had failed to improve on irrigation are now being treated with the endoscope and are rapidly improving.

33. Tracheal Obstruction Due to Thymus.—The interesting points of Lynah's case are that the dyspnea caused by the enlarged thymus was relieved by intubation, but returned shortly after the removal of the tube, that the patient, aged 3½ years, being of a type associated with status lymphaticus, could receive two injections of antitoxic serums without any anaphylaxis or fatal result and only have a slight erythema following the administration of the first dose; that the child, while asthmatic since birth, has never had convulsions. The child was wheezing like an old asthmatic. There was an area of dulness over the upper end of the sternum, the upper limit of the first intercostal space extending downward to about the fourth intercostal space; the lateral diameter from 3 cm. to the right of the median line and 2 cm. to the left.

41. Development of Antibodies.—The results of his experiments are summarized by Clough as follows: Of twelve cases, in which satisfactory protection tests were carried out with the serums of patients after crisis, or lysis, using the homologous strain of pneumococcus, nine had serums which showed definite protective power for mice as compared with normal serum. The serums of three gave negative results; in these three cases but one specimen of serum was tested. In two of the cases, the serum of which showed protective power after the crisis, specimens of serum obtained during the acute stage of the disease showed no such power. Further, in two other cases, one fatal, in which the serum was examined only during the acute stage, no protection was manifested. These serums, which protected mice from the homologous strain, were also tested with an heterologous strain, and showed no protective power toward that strain. Occasionally protective power cannot be demonstrated unless the serum is tested at frequent intervals during convalescence.

With but two exceptions, all the strains isolated were not phagocytable in fresh normal human serum, and were presumably virulent for man. The two other strains, which seemed identical with one another in every respect, were highly virulent for mice. As one was cultivated from the blood of a patient a few days before death, it seems most reasonable to regard it as also virulent for man, in spite of its phagocytability in normal human serum. This suggests the advisability of greater caution in assuming that the virulence of an organism for man is always parallel with its resistance to phagocytosis in the test-tube.

Of eleven cases in which the phagocytic activity of the serum after crisis, or lysis, was tested *in vitro*, six showed definite activity. In five, negative results were obtained. In some of these, at least, positive results would probably have been obtained had suitable variations in technic been employed. This activity has a significance which is quite different from that of a rise in opsonic index, which has often been described, but is qualitatively comparable with the activity of potent immune serum, in that it brings about active phagocytosis of a virulent pneumococcus, not phagocytable in normal human serum. In two of these cases serum examined before the crisis showed no such activity. The serum of a fatal case was also inactive. This phagocytic activity, with one exception, was strictly limited to the homologous strain, derived from the patient whose serum was being tested.

The active substances in the serum are bacteriotropins, in the sense of Neufeld, since they resist heating at 56 C., and persist in the serum *in vitro* for a considerable period. In both of two cases tested, phagocytosis in the peritoneum of the mouse closely paralleled phagocytosis in the test-tube. Intracellular digestion of the cocci, as shown by changes in staining reaction, was marked in both cases. The phagocytic activity of the serum ran closely parallel with its protective power for mice, both in incidence, in time of appearance and in strict specificity as to the strain of pneumococcus affected. It, therefore, seems justifiable to Clough to conclude that the protective action of the serum depends on, and is due directly to, its power of promoting phagocytosis.

48. Fate of Tartrates in Body.—Under the experimental conditions outlined by the authors, sodium tartrate subcutaneously introduced into rabbits failed to reappear in the urine. It is concluded that the disintegrative influence of the salt on the convoluted tubules is sufficient to account for the failure of the salt to be eliminated. No evidence of a vicarious function on the part of the glomerulus was observed.

49. Tartrate Nephritis.—It is indicated that the introduction of a sufficiency of alkali into animals in a state of fasting permits a greater elimination of urinary constituents during tartrate nephritis than obtains under similar circumstances when the alkali is omitted. Histologically there is evidence that the administration of alkali exerts a slight modifying action.

50. Renal Secretion during Tartrate Nephritis.—After the intravenous introduction of a solution containing sodium chlorid and urea into the rabbit during pronounced tartrate nephritis, all the chlorid reappeared in the urine within forty-eight hours. On the other hand, the nitrogen of the urine remained far below that usually eliminated by the normal animal under the experimental conditions; in other words, little or none of the urea injected was excreted by the kidney. In the light of the histologic findings these results are interpreted by the authors to mean that under normal conditions chlorids and water are passed through the glomerular mechanism, whereas urea becomes a urinary constituent by way of the convoluted tubules. These results constitute a direct confirmation of the older observations of others concerning the elimination by the kidney of the substances under discussion.

No evidence was obtained that the glomerulus may take over the function of the tubular epithelium.

51. **Blood-Flow in Feet.**—The blood-flow in the feet, according to Stewart, is smaller per unit of volume of the part than in the hand, the ratio of foot flow to hand flow per 100 cubic centimeters of the part usually lying in normal persons between 1 to 3 and 1 to 2. In the supine position, with the legs hanging down, the flow in the feet seems to be somewhat greater than in the sitting position.

52. **Blood-Flow in Feet and Fever.**—In the cases of fever investigated by Stewart the flow in the feet never exceeded the normal flow and was usually much below the normal. In explanation of the relatively small foot flow in the fever cases it is suggested that the vasoconstrictor mechanism of the peripheral parts, especially of the skin, is abnormally excited, and some direct evidence that this is the case is brought forward. The significance of this hypersensitiveness, or at least increased action, of the cutaneous vasoconstrictor mechanism is assumed to be that the peripheral vasoconstriction is a compensatory arrangement which secures for the organs mainly suffering from the infective process an increased flow of blood. On this hypothesis the rise of temperature is, chiefly at least, secondary, inevitably following the vasoconstriction, provided that the metabolism is, on the whole, not diminished. Accordingly the rational treatment of hyperpyrexia or of pyrexia if it is considered necessary to treat it, is to abstract heat by a process which will not diminish and may even increase the cutaneous vasoconstriction. This condition is exactly fulfilled by the cold bath, at least as regards its initial effect. Other so-called tonic effects of the cold bath are not considered here. Antipyretic drugs which act by dilating the cutaneous vessels would seem to be inferior in this regard. They diminish the temperature, it is true, but at the cost of defeating the beneficial redistribution of the blood which it is the function of the peripheral vasoconstriction to insure.

It is obvious, says Stewart, that for the elimination of a given quantity of heat from the skin by radiation and conduction in fever, a smaller cutaneous blood-flow will suffice than with normal body temperature, since the elimination of heat per gram of blood passing through the surface must be greater in fever owing to the greater difference of temperature between the surface of the body and its surroundings.

53. **Blood in Rats Recovered from Implanted Sarcoma.**—The studies reported by Weil were made in the attempt to determine whether the factor of immunity can be demonstrated in the blood of animals which have recovered from implanted tumors. Two series of experiments were carried out, each from a different point of view. In the first series large amounts of immune blood plasma were injected into animals with growing tumors, and also into normal animals subsequently implanted with tumors, in order to determine the effect on the tumor process. Twenty-four young white rats were included. These were divided into two equal lots of twelve each. Of the first lot, six rats received intravenous injection into the jugular vein of 1 c.c. of plasma, obtained from recovered rats. One cubic centimeter represents the average amount of plasma which it was possible to obtain from one rat. The other six received 2 c.c. of the same plasma intraperitoneally. On the day following this injection all the animals received a subcutaneous inoculation, by the trocar method, of rat sarcoma.

After ten days the animals were examined. Of the treated series, nine, and of the untreated series, ten, showed growths. On the eighteenth day the animals were again examined. Of the treated series ten remained alive, of which again nine showed tumors. Of the untreated series the total number remained alive, and ten showed tumors. There were no quantitative differences discernible in the average growth of the tumors. On the thirtieth day there had been retrogression in all except four of the treated series, and in all except three of the untreated series. At this point the observation of both series was discontinued. The conclusion was drawn that the preliminary inoculation of immune serum does not protect rats against subsequent implantation of tumors and does not noticeably influence the rate of growth nor the percentage of retrogressions in such tumors.

In another series of animals the conditions of the experiment were varied by making, in addition to the preliminary treatment with immune serum on the day preceding the tumor inoculation, a subsequent injection of serum five days thereafter. The treatment produced no therapeutic effect. Weil states that theoretically it is possible that immune substances may be ineffective in preventing successful implantation, whereas they may be of importance in controlling growth. In order to determine this point rats were selected whose tumors had shown progressive growth, and had reached a size measuring not less than 1.5 centimeters in diameter. Fourteen animals were selected for treatment. All the animals had been inoculated twenty-five days previously. There were 100 per cent. of takes; and on the day on which observation began all of the tumors were actively growing and showed no ulceration. The rate of growth of each tumor was plotted by a second observation made ten days later, or on the thirty-fifth day after inoculation. On that day each of the animals received an injection of immune plasma. In all the animals three further injections at intervals of two days were made intraperitoneally. All but two of the animals survived the treatment and were in good condition. In all the twelve that survived, except two, there had been continuous striking increase in the growth of the tumor, which at this stage is unusually active. In the two exceptions there had been retrogression which, in one, had been almost complete. Comparison with the controls brought out the fact that the percentage of retrogressions in this series was greater by 12 per cent. than in the treated animals. The conclusion is drawn that the repeated injection of plasma, derived from immune rats, failed to influence favorably the growth of a certain strain of rat sarcoma. Therefore, as far as the results of this series of experiments justify generalization, it is concluded that the blood of recovered rats does not carry the factor of immunity present in these animals.

In the second series of experiments, recovered rats received a series of subcutaneous inoculations of tumor extract, in order, if possible, to heighten their immunity. The animals were then bled and the plasma was injected into guinea-pigs, as in the previous series. In this series again, however, there was complete failure to demonstrate sensitization. The conclusion is therefore drawn that it is impossible, by means of the passive sensitization of guinea-pigs, to demonstrate the presence of immune substances in the blood of rats recovered from an implanted sarcoma, or in the blood of rats recovered from this tumor and subsequently injected therewith.

54. **Metastasis Formation in Experimental Cancer.**—The analysis of the results of Levin's investigation shows that the differences in the frequency of the occurrence and in the specific localization of metastases are not due to the ease of detachment of the cancer cells from the primary tumor. Nor does the difference in the mode of transportation play a part. The main factors in determining the localization and frequency of metastases are the character and malignancy of the cancer cell on the one hand, and the general and local susceptibility of the organism of the host on the other. The failure or success of the proliferation of a group of cancer cells transported from the primary tumor into a distant organ is a result of the interaction of these two causes.

56. **Regeneration of Axis Cylinders in Vitro.**—It is shown for the first time by Ingebrigtsen that nerve fibers grow out from pieces of cerebellum of young cats and guinea-pigs when culitvated in coagulated plasma. The same phenomenon has been observed in cultures of spinal ganglia. The nerve fibers do not anastomose and they extend into the plasma unaccompanied by structures of any kind.

59. **Spirocheticidal Action of Serum of Patients Treated with Salvarsan.**—The authors found that the serum of rabbits treated intravenously with neosalvarsan, and of syphilitic patients treated intravenously with salvarsan or neosalvarsan, has a definite spirochaeticidal action on *Spirochaeta*

duttoni. Although this spirocheticidal action is exerted *in vitro* it can be demonstrated only after the treated spirochaetae are injected into susceptible animals. A curative action of the serum of neosalvarsan-treated rabbits is exercised on mice infected with *Spirochaeta duttoni.* The spirocheticidal action of the serum of salvarsan treated rabbits and patients is markedly increased by heating at 56 C. for thirty minutes. The increased spirocheticidal action produced by heating is due in part to the destruction of some inhibitory substance contained in normal serum and in part to a direct effect of the heat on the serum and salvarsan mixture. Cerebrospinal fluid does not contain the inhibitory substance present in normal unheated serum.

60. **Electrocardiographic Study of Anaphylactic Rabbit.**—Electrocardiographic examination of rabbits during the anaphylactic reaction by Auer and Robinson revealed marked and various changes of the heart's activity in twenty-two out of twenty-four animals. Changes occurred in fatal as well as in non-fatal cases, after the vagi were cut as well as when they were intact. Cardiac disturbances are thus a practically constant result of serum anaphylaxis in the rabbit. The authors suggest that it therefore is possible that anaphylaxis plays a rôle in the causatiaon of certain cardiac derangements in man.

61. **Microorganism Causing Epidemic Poliomyelitis.** — By employing a specially devised method Flexner and Noguchi have cultivated from the central nervous tissues of human beings and monkeys the subjects of epidemic poliomyelitis a peculiar minute organism that has been caused to reproduce the symptoms and lesions of experimental poliomyelitis. The microorganism consists of globoid bodies measuring from 0.15 to 0.3 of a micron in diameter, and arranged in pairs, chains and masses according to the conditions of growth and multiplication. The chain formation takes place in a fluid medium, the other groupings in both solid and fluid media. Within the tissues of infected human beings and animals the chains do not appear. No statement is ventured by the authors as to the place among living things to which the bodies belong. It is obvious that the cultural conditions are those that apply more particularly to the bacteria. The microorganism passes through Berkefield filters and the filtrates yield on recultivation the particular microorganism contained within the filtered culture. By employing a suitable staining method the microorganism has been detected in film preparations and sections prepared from human nervous tissues, and from the corresponding tissues of monkeys inoculated with the usual virus or with cultures or filtrates prepared from monkeys previously injected with cultures.

From all the infected materials mentioned, irrespective of the manner of their origin, the microorganism has been recovered in cultures. As would be expected, it is more uniformly recoverable from the original nervous tissues than from filtrates and doubtless for the reason that in the former it exists in greater abundance. An etiologic relationship has been shown to exist between the cultivated microorganism and epidemic poliomyelitis as it occurs in human beings or in monkeys. The authors describe their technic fully.

88. **Hospital Growth Marks Dawn of New Era.**—The modern hospital, says Ochsner, gives the public vastly more in the way of facilities for diagnosis, for furthering the progress of the case, with the smallest possible amount of discomfort. It provides for every form of apparatus for investigation during the entire period that the patient is confined to the institution. It provides facilities for all patients which could not have been commanded even by the very wealthiest persons only a quarter of a century ago, and it is but natural that such facilities must be expensive, but, with all of this, it is well not to lose sight of the fact that in the development and maintenance of these features there is great danger of enormous extravagance on the one side and hopeless waste on the other until the standardization of hospitals has been developed from the economical side by capable hospital specialists, and until those interested have been made familiar with this development through an advanced hospital journalism.

91. **The Hospital Unit.**—The hospital unit in Goldwater's opinion has served its day and purpose. To-day it is a stumbling-block in the road to hospital progress. Let us, therefore, by a common effort put it aside and turn to it only as we have need for it. No longer should it be permitted to occupy the middle of the road. He who looks on the hospital

unit as a miniature but complete hospital has failed to read aright the signs of the times. To-day the hospital unit is dependent not only on the central equipment of power plant, domestic service, etc., but on other ward units, designed primarily for other and specialized work. The internist, the general surgeon, the regional specialist, can no longer stand alone: therefore the ward unit, which is the clinician's workshop, has ceased to be an independent unit. The needs of the patients determine the right relation of members of the hospital staff to each other; to facilitate their relations is the great aim of modern hospital organization and construction. A single ward and its accessories no longer constitute a "hospital unit." To-day a ward is an incomplete fragment—the hospital is itself the unit.

112. Differential Diagnosis of Appendix by Roentgenoscopy.—In the examination of 141 cases between May 1, 1913, and September 15, 1913, data were obtained by Quimby which enabled him to classify the appendix roentgenographically. Of this number, fifty patients had had laparotomies previous to the examination in which the appendix had been removed. Of the remainder, 90 per cent. gave sufficient data to determine the position and condition of the appendix. The remaining 10 per cent. were those in whom the position of the cecum prohibited its thorough inspection.

125. Cancer of Lower Lip.—The customary procedure employed by the Mayos in operating for cancer of the lower lip is described by Beckman. An incision is made three-fourths of an inch below the ramus of the jaw from one sternomastoid muscle to the other. This incision extends through the skin and platysma muscle. The reason for making the incision as low as this is to avoid the small branch of the facial nerve which swings down below the angle of the jaw and then returns on the face to supply the muscles about the angle of the mouth. Where it is necessary to remove only a small portion of the middle of the lip, Beckman says, a better cosmetic result is obtained by saving these branches of the facial nerves. If, however, it is necessary to remove more of the lower lip and widen the mouth by extending into the cheek, it is not necessary to save these nerves.

Through this incision the skin and platysma muscle are reflected down to the hyoid bone and up to the inferior maxilla. All of the fascia and fat, including the submaxillary salivary glands, are removed from the submental and submaxillary triangles. It is necessary to ligate both the facial artery and vein. The blood-supply to the face is so abundant through the other branches of the external carotid that no sloughing from this cause has been seen. The hypoglossal nerve and the lingual branch of the trifacial are exposed on each side and should be saved. After the removal of the glands this primary incision is closed, drainage being established through small separate incisions on each side. The platysma muscle is stitched first and then the skin with a subcutaneous suture. The wound in the neck is then carefully protected and the operation on the lip begun.

A quadrilateral section, including the full thickness of the entire lip, is removed, running down nearly to the point of the chin. The section removed should include the growth and from one-fourth to one-half inch on each side into the healthy tissues. The coronary artery should be tied on each side. An incision is then made from the lower angle of the quadrilateral parallel to the ramus of the jaw on either side as far as is necessary to obtain enough tissue to close the defect. The entire flap from which the new lower lip is to be made should be freed well from the bone. These flaps are then sutured together in the mid-line with silkworm gut sutures, the skin being approximated with horse-hair. If the skin remaining over the point of the chin is too long to be approximated to the new lip so that it produces wrinkles, it is shortened by taking out a small triangle at one or both ends of the incision as shown by the accompanying diagram.

This is the technic employed in cases in which only a small portion of the lip is removed. If one-half or more of the lower lip must be removed, the primary incision is made in precisely the same way. In addition to the incision running from the lower end of the quadrilateral piece along the ramus of the jaw, it is now necessary to make incisions parallel to the former, extending from the corners of the mouth directly into the cheek. These incisions should extend slightly downward rather than upward. When the flaps on each side are thoroughly free, they are approximated as in the former case, the only difference being that the raw surface of the lower lip must be covered with mucous membrane as just mentioned. It is now seen that the lower lip is shorter than the upper, and also shorter than the skin remaining on the chin. These two latter are shortened by removing triangular pieces from the extremity of each incision, as shown in the diagram.

This plastic work was originated by C. H. Mayo and has not been described in the literature. From Jan. 1, 1907, to Dec. 31, 1911, there were 199 patients with cancer of the lower lip observed in the Mayo Clinic. Twenty-five of these 199 cases were diagnosed from clinical findings only and consequently cannot be proved definitely to have been cancer. The remaining 174 cases have been proved to be cancer by both clinical and pathologic diagnosis. One hundred twenty-six patients had a radical operation performed as the first operation. Ninety-nine of these patients have been traced. Eighty-three have no sign of a recurrence either locally or in the glands of the neck. Sixteen have either died of their original trouble or now have a recurrence. Seven of these sixteen patients had glands involved at the time of their operation and three others had an extensive growth on the lip. Two of the 83 patients were examined just one year ago; 25, between one and two years; 17 between two and three years; and 4 over five years. In 18 of the above number glandular involvement was demonstrated by the microscope at the time of their operation and 9 of these, or 50 per cent., are among the cured cases. Twenty-five patients had a late radical operation, that is, removal of the glands of the neck following one or two local operations on the lip or following treatment by paste. Twenty of these patients have been traced. Fourteen are classified as cured and six as not cured, giving a percentage of 70 per cent. of cures in those patients having a late radical operation as compared with 83.6 per cent. of cures in cases that had radical operations as the primary treatment.

10. Treatment of Inoperable Cancer.—Rowntree is of the opinion that at present we do not do enough for our cases of advanced cancer, and is convinced that the immediate future holds out a good deal of promise as regards the palliation of this miserable condition. An important preliminary to this should, he thinks, consist in the banishment of the dreadful sense of hopelessness and finality that the present usage of the word "inoperable" creates. He favors the performance of limited operations for the alleviation of incurable cases of cancer.

11. Reaction of Blood-Serum in Cancer.—The method described by Sturrock is based on that of Moore and Wilson, but contains several modifications which he believes increases its clinical value. He examined many cases by Moore and Wilson's method, but found definite results difficult to obtain. The veins of the forearm are engorged, a suitable vein is chosen, and the overlying skin purified; the vein is then punctured with the needle of an antitoxin syringe, and the issuing blood collected in a small test-tube of about 3 c.c. capacity. The tube is rather more than half filled and the mouth closed with a plug of cotton-wool. It is then left in a vertical position for twenty-four hours, and afterward centrifugalized to obtain clear serum.

A series of dilutions of normal sulphuric acid is prepared and kept in well-stoppered bottles; the dilutions run in series as follows: fourth-normal, four and five-tenths normal, fifth-normal, etc., to seventh-normal, and are thus seven in number. They must be tested from time to time against sodium carbonate of known strength, and should be found to remain constant for a considerable time. When required for use, a small quantity of acid is, after shaking, poured into a watch-glass or, preferably, a small glass staining dish.

Two drops of a 1 per cent. alcoholic solution of dimethyl are dropped on a filter paper. A small quantity of distilled water is then drawn into a capillary pipet, a bubble of air allowed to follow, and, after this, serum drawn as far as a mark about 3 cm. up the pipet; a second bubble of air is then admitted, and, finally, the particular acid solution required is drawn up to the same mark. The pipet now contains equal quantities of serum and acid and a trace of distilled water. The contents are blown out on a porcelain slab, thoroughly mixed by aspiration, and finally blown out on the center of the dimethyl drop. If no pink appears in the center of the yellow drop, the process is carried out with stronger acid solution till the pink change first occurs. If, on the other hand, pink appears at the first attempt, weaker acids are used until the change is no longer obtained. The dilution which gives the first pink reaction is taken as the index; if, for instance, pink appears with fifth-normal acid, but not with five and five-tenths normal, the alkalinity to dimethyl of the serum is reckoned as equivalent to fifth-normal or two-tenths normal.

To prevent absorption of alkali from glass, all the glass materials used are subjected to immersion in strong hydrochloric acid, and are afterward thoroughly washed in distilled water and finally dried in an oven at 110 C. (230 F.). The average alkalinity of the cancer series examined was one hundred and ninety thousandth normal, higher than that of the non-malignant—that is, one hundred and seventy-three thousandth normal. It appears that a reading of two-tenths normal or over affords some presumption of the presence of cancer, and in Sturrock's opinion it is sufficient to justify an exploratory operation in doubtful cases.

24. Failure of Women to Nurse Their Infants.—The truth of the statement that modern women, just because they are modern women, far removed from the primitive conditions of life, suffer from any degeneration of the mammary gland is denied by Cameron. He says that there is no proof whatever that racial development is in the direction of atrophy of the gland or of degeneration of its functions. Secondly, he points out that we should remember that the force which brings the mammary gland to free secretion is provided by the vigorous sucking of the child. When the infant is born there is but little milk in the breast, while in a few days, after a strong, healthy infant has begun to suck, milk flows in abundance. If two infants are nursed the amount of milk doubles itself; if one is taken away the amount is reduced by half. Cameron knows no way in which the secretion of milk can be stopped save by a complete removal of the child. Lastly, and most significantly of all, if for any reason only one breast is used, that breast alone secretes milk, while the other remains dry.

These commonplace observations, Cameron states, show that the main factors which determine the initial secretion of milk in the mother's breast reside in the child and not in the mother. When the child has a good appetite, sucks well and empties the breast completely the amount of milk secreted increases with each nursing. Let some accident diminish his appetite for a few days—some slight pyrexial disorder, for example, or a trifling dyspepsia—then with diminished suction less milk is secreted, and the infant involuntarily imposes on himself a period of partial starvation.

There is, however, a second provision against the danger of overfeeding and dyspepsia in breast-fed infants. The composition of milk varies within wide limits during a single nursing. The first milk drawn off is relatively dilute; the last milk is so rich in fat that it may almost be considered as cream. With feeble suction and insufficient emptying of the breast the last concentrated milk is not obtained, and the food of the sick child becomes relatively dilute. In these two ways Nature guards very efficiently against overfeeding, and as a result dyspepsia from simple overfeeding is a much less common and less severe disorder in breast-fed infants than in those babies who are fed on the bottle, the contents of which are of unvarying composition and always ready to flow freely into the infant's mouth in response to a minimum of effort on his part.

In some cases, however, Nature seems to have been, as it were, overcareful—to guard so well against the overfeeding of the feeble or sick infant as to cause some risk of inanition and drying up of the mother's breast. This is especially so, Cameron thinks, in first-born infants. No doubt the first labor is prone to be protracted and difficult, and the child as a result tends to be exhausted or even slightly asphyxiated, and is apt to lie in a drowsy condition, with little appetite and little vigor in sucking. Apart from this effect on the child, which in all but a few severe cases is quite transitory, the breast which is becoming functional for the first time is slower to secrete and requires a greater effort on the part of the child than does the breast of a multipara. At any rate, there appear to be but few cases in which the first baby suffers severely from inanition while the later children thrive from the beginning. On the other hand, when the nursing of the first child has been very easy, the second is more likely to suffer from dyspepsia as the result of overfeeding. Although no doubt women differ considerably in their response to the stimulus of the infants' sucking, it remains true that the main factor which controls the secretion of milk is provided by the sucking of the child.

Overwork and underfeeding of the mother in the later months of lactation can doubtless produce deterioration of the quality of the milk, but in the first establishment of the milk the part of the mother, provided that the nipples are well formed, is comparatively a passive one, and the breasts of a woman in the last stages of exhaustion from some debilitating disease may be full of milk for some time after labor, provided only that the child is strong and hungry.

25. **Syphilis and State Control.**—French's essential opinions in the control of prostitution and venereal diseases culled from twenty years' practical experience in many countries are as follows: Confidential medical notification of disease on prima facie evidence and medical treatment for short periods in hospital in the early actively contagious stages of disease, the steps taken being dependent on environment and the circumstances of the individual case. The effectual control of openly practiced prostitution by adequate police measures for irreclaimable prostitutes. The rigid suppression of souteneurs who act as middlemen and live on the earnings of women, and even marry with this object in view. The protection of orphan children and minors and the suppression of begging in the streets by children under 12 years of age. The suppression of loitering and solicitation in the streets by women or men acting on their behalf. The provision of "free voluntary dispensaries" where women who do not openly practice prostitution (clandestines) may be treated and reclaimed. Removal of disorderly persons from the towns, and measures to prevent the return of evicted persons, and to prevent harboring of diseased merchant seamen, who spread the worst form of disease at seaport towns. Control of persons seeking medical aid from chemists for venereal diseases, who spread their complaints broadcast and maintain syphilis in perpetuity. Circumcision of male infants and all recruits entering the army with phimosis. Punishment by fine or imprisonment for concealing disease, or for transmitting it knowingly to another. The marriage of syphilitics discouraged by law under ten years from date of contracting the disease.

26. **Bacillus Lepræ.**—Material for purposes of cultivation on various mediums has now been obtained by Fraser and Fletcher from thirty-two non-ulcerating nodular cases of leprosy, and 373 inoculations made on the various culture mediums. They have consistently failed to obtain a culture of the *Bacillus leprae*. There is no doubt in the author's minds that material swarming with bacilli has been employed on each occasion. This was clearly demonstrated by the microscopic examinations which were made in every case. From the examinations made of nodules which have been incubated on culture mediums for periods ranging from a few days to nine months, no evidence has been obtained that the bacilli had increased or lessened in number. They point out that any one who has examined smears prepared from freshly excised leper tissues must be struck with the enormous masses of acid-fast bacilli present, and they are unable to comprehend how it is possible to state in a case in which no macroscopic growth is apparent that an increase, recognizable only by the microscope, has occurred.

29. **Umbilical Hernia in Children.**—The operation is not performed by Fraser on children below the age of 6 months, and in the majority of cases, he says, it is of advantage to wait until the child is 1 year old. During the preoperation period the application of a pad or of inversion may be practiced, and if cure results without operation so much the better. The size of the opening in the abdominal wall is considered in judging the suitability of the case. A large opening is unsuitable for operation by this method, as there is later a tendency to recurrence. The rough guide which Fraser uses is the tip of the little finger—an opening which is large enough to admit this is considered unsuitable. It is essential that the sac be empty; irreducible contents of any description whatsoever must be looked on as an absolute contra-indication to the operation. As long as the opening in the parietes is suitable the size of the sac need not be taken into consideration. The method has been practiced on twenty-one patients. The procedure does not occupy more than a couple of minutes in the accomplishment, and the after-treatment is of the most simple description. The preliminary treatment consists in a thorough evacuation of the bowels and the reduction of flatulence by suitable dietary before operation. The essential material is a piece of elastic cord ⅛ inch in diameter and about 3 inches long.

The technic of the operation is as follows: The skin over the fundus of the protrusion is grasped with a pair of dissecting forceps, and skin and sac are pulled gently upward from the abdominal wall. Great care is exercised in ascertaining that the contents of the sac are completely reduced. Three small incisions are made at equal intervals around the periphery of the sac, at the point where the skin is reflected on the abdominal wall. These incisions penetrate the skin and subcutaneous tissues, but they must not injure the sac. With a blunt dissector it is now possible to undermine the tissues around the pedicle of the sac—the three radiatory incisions facilitate the performance of this. The elastic ligature is now pulled beneath the skin, following the track of separation. This is most conveniently done by means of an artery forceps, which pulls the ligature as tightly as possible around the pedicle of the sac and fastens it so with a stout piece of silk. The ends of the elastic ligature are left protruding through one of the incisions, and they are cut to a convenient length; a simple dressing is applied and kept in position by means of a band of adhesive plaster. The ligature is allowed to remain in position for six days and then removed by cutting the silk knot. The opening which it leaves quickly closes.

31. **Suppurating Endothelioma.**—In Carwardine's case free fluid was present in the peritoneum, serous generally, but puriform in the right loin. A gangrenous broken-down mass was found, originating in a Meckel's diverticulum, and necessitating the resection of 15 inches of the small intestine. The appendix was normal. The patient remains well.

37. **Testing for Occult Gastro-Intestinal Hemorrhage.**—Hallez fed animals with measured amounts of blood and then applied to the stools and stomach content the various tests in vogue to detect invisible blood. The conditions thus closely approximated those with natural hemorrhage in the stomach or bowel, and the findings confirmed anew the remarkable delicacy of the current tests, especially the Weber, the Meyer and the Adler technics. No meat or raw vegetables should be eaten for three days before the test is applied, and no drugs taken.

40 *Initial Localization of Pulmonary Tuberculosis in Children and Involvement of the Apex. C. Leroux.
41 Pediatrics in Connection with General Welfare Work for Children. E. Deutsch.

40. **Initial Localization of Pulmonary Tuberculosis in Children.**—Leroux gives a number of skiagrams of children to sustain his assumption that in infants and quite young children the initial localization of tuberculous infection is toward the base or the middle part of the lung in the majority of cases. The focus even with involvement of adjoining lymph-nodes and later of the corresponding lymph-nodes on the other side, may give no clinical sign of its presence, but it shows up on roentgenoscopy. Before the age of 2, the tuberculous process generally proves fatal, but after this age skiagrams taken at intervals during months and years show that the pulmonary affection usually passes through three phases: first there is the primary focus, then a stage of tuberculous processes in the tracheobronchial lymph-nodes, and then the apex becomes involved or there is secondary reinoculation of the apex. In older children, as in adults, the primary process seems to localize preferably at the apex; the lymph-nodes are affected only secondarily or later, but they become involved more regularly than is the case in adults. The skiagrams given show the low focus, then the phase of involvement of the tracheobronchial lymph-nodes, and finally the involvement of the apex. This is the usual course in young children. In children of 10 or more the apex is first involved and later the tracheobronchial lymph-nodes and the apical process heals in the favorable cases, and later the lymph-nodes.

47 Spontaneous Rupture of Ovarian Cyst During General Anesthesia; Two Cases. M. Patel.

45. **Pyelonephritis of Pregnancy.**—Pasteau insists on the great difference between pyelonephritis developing in the course of pregnancy or developing first after delivery. The former should be treated by simple measures, therapeutic distention of the bladder to its physiologic capacity, the patient reclining with only the head raised above the plane of the bed, with hexamethylenamin to sterilize the urine. This reduces the congestion in the small pelvis, stimulates the kidney secretion and modifies the urine, and thus combats the causes of the retention and helps in the evacuation of the kidneys. These measures alone generally suffice, and a complete transformation and cure usually follow delivery. The indications are quite different with pyelonephritis coming on after delivery. This requires systematic catheterization of the ureter, evacuating and rinsing out the kidney pelvis. The trouble in this case must be treated with the greatest care and perseverance or the kidneys are liable to become seriously and permanently impaired. Only when there is great distention of the kidney, with fever and a bad general condition, is nephrostomy indicated, but when this is needed, it often brings about a complete cure.

48 *Diagnosis of Tuberculous Salpingitis. R. de Bovis.

September 24, No. 39, pp. 457-468

49 *The Renal Element in Glycosuria. R. Lépine.

48. **Diagnosis of Tuberculous Salpingitis.**—De Bovis remarks that tuberculous processes in the uterine adnexa are more frequent than generally recognized; Labhardt found them in 22 per cent. of all his ovary and tube patients. In differentiation, bacteriologic examination of the uterine secretions, the infantile status of the genital organs, menstrual disturbances, persisting fever and recurring mild diarrhea or symptoms of mild pelvic peritonitis—all these speak for a tuberculous process in the adnexa, while tuberculin tests do not reveal whether the tuberculous lesions are here or in the lungs or elsewhere. In virgins or in women who have never had puerperal complications or have never been exposed to gonorrhea, salpingitis is almost invariably of tuberculous origin. Lesions of this nature are liable to fluctuate in size as the tube becomes obstructed or becomes the seat of congestion from various causes. These transient congestions are probably responsible for the recurring mild peritonitis symptoms. Castano recently based his diagnosis on this sign, having witnessed that the tubes varied from the size of an egg to that of an orange at different times and became very painful, and tubercle bacilli were found in the discharge from the uterus. Variable palpation findings of this kind are more regular and constant with tuberculous salpingitis than with any other conditions, and this variability affords strong presumptive evidence of the tuberculous nature of the trouble in the adnexa.

49. **The Renal Element in Glycosuria.**—Lépine called attention to the subject some eighteen years ago, and here analyzes the various communications on renal diabetes and phloridzin glycosuria that have been published since that date. He suggests in regard to phloridzin glycosuria that the molecules of the phloridzin and its derivatives can pass through the kidney only by an actual effraction, that is, breaking their passage through by force. Sugar molecules, following in their steps, can slip through the breaches thus produced in the kidney filter. This explains how we get the clinical picture of glycosuria with only the normal proportion of sugar in the blood or even less than this.

54 Local Conditions Predisposing to Pulmonary Tuberculosis. A. Bacmeister.

50. **Treatment of Hemoptysis with Saline Infusion.**—Müller calls attention to the often remarkable effect of intravenous saline infusion in arresting hemorrhage, and commends it in treatment of hemoptysis. Salt promotes coagulation, and it is an old traditional remedy for hemorrhage; von den Velden by systematic experiment and clinical research has confirmed its efficacy in this line and explained in part the mechanism of its action. He attributes it to the marked exchange of fluids between the blood and the tissues under the modification of osmotic conditions which follows ingestion or injection of salt. This evidently mobilizes substances which promote coagulation, and the effect is naturally more rapid and more intense when the salt solution is injected directly into the blood stream. The blood becomes more fluid and at once it coagulates more readily, the maximum effect being reached in fifteen or twenty minutes and then subsiding in the course of an hour. He reported in 1909 seven cases of hemoptysis in which the tendency to hemorrhage was thus arrested at once. Müller has found only four articles on the subject published since, and none of a comprehensive character like the communication he here presents. In it he reviews his experiences with the measure in fifty cases during the last eighteen months, giving the details of each case, classified according to the extent of the hemorrhage and the stage of the pulmonary tuberculosis. He does not hesitate to affirm that infusion of a hypertonic salt solution is more reliable than any other measure to date. The best technic seems to be by intravenous injection of 5 c.c. of a 10 or 15 per cent. solution of salt. The injections are entirely harmless, he states, and cause no pain. All tendency to hemoptysis is arrested almost without fail in case of slight or moderate bleeding (up to 100 c.c.), in the predominantly fibrous form of pulmonary tuberculosis. With more than 100 c.c. of blood, the injection often answers the desired purpose, and hence should always be tried, although it sometimes fails. The fibrous form of tuberculosis is more amenable to the measure than the ulcerative. In only five of the total fifty cases was no benefit observed; in twenty-one cases the tendency to hemorrhage was permanently arrested; in thirty-five cases the hemorrhage was arrested at once but it returned a few days later in fourteen in this group. In four other cases the existing hemorrhage was not modified, but the hemorrhagic tendency thereafter seemed to have been arrested. The injection should be given during the hemorrhage and after its arrest he recommends a second and possibly a third injection during the day to ward off recurrence. Müller comments on the depressing influence of hemoptysis on both body and mind, and the advantages of arresting it at once by this simple and harmless measure which can be applied by any practitioner. If the tendency to hemorrhage fails to yield to the saline infusion, he advises a therapeutic pneumothorax or thoracoplastic operation to squeeze the lung into smaller compass and thus mechanically conquer the tendency to hemorrhage.

52. **Medical Inspection of Entire Community.**—The village in question has a population of 470 and the authorities sent Fürbringer to examine into the causes of the exceptionally high death-rate from tuberculosis. His research seems to have been conducted along model lines and he emphasizes the important lessons learned from this intensive study of public-health conditions in a small poverty-stricken community. He regards the lack of training in domestic science, in vegetable gardening and in raising rabbits for meat, as the predominant factors in the general thriftlessness and consequent liquor drinking and morbidity. The income of the families is rarely over $175 a year, and never much higher, and yet the average expenditure of each family for liquor was $51 in the last year for which the figures are obtainable.

53. **Therapeutic Pneumothorax in Treatment of Tuberculous Empyema in the Pleura.**—Rösler has only two cases to report, but the results were excellent in these very serious and advanced cases. He consequently commends evacuation of the cavity and injection of nitrogen in its place as an important measure in all such suppurative exudates over a tuberculous lung. The distressing symptoms were relieved at once and cough and expectoration subsided entirely in one case. In the other, the tuberculous laryngitis and enteritis continued their course but life was prolonged and rendered bearable. The greater or less tendency to cirrhosis displayed by the lung tissue is evidently the deciding factor as to the outcome in tuberculous pulmonary affections.

59. **Correction of Deformity of the Jaws.**—Grünberg pleads for the cooperation of dentists and orthopedists to correct protruding or receding jaws in order to make the teeth work better and thus improve the general health while improving the appearance. He merely seeks to have the principles advocated by E. H. Angle better understood and applied more generally. The article is accompanied by twenty illustrations showing conditions "before and after," and illustrating anew the advantages of orthodontia.

61. **The Reflexes.**—Trömner gives an illustrated description of his methods for eliciting tendon and muscle reflexes, and discusses the signs of attenuation or exaggeration of reflex action. He insists that the whole science of reflex action is much simpler than generally recognized, and that reflex irritability is a physiologic property of every voluntary muscle. Many more reflexes can be elicited in the healthy than has hitherto been deemed possible. Different persons vary in this respect; in some twenty different reflexes can be elicited; in others only four. He has never encountered but one person in whom it was impossible to elicit any reflex action except a weak knee-jerk. He states that it is possible to elicit some of the ordinary reflexes by several methods instead of the classic one usually followed; the Achilles reflex, for instance, can be induced, even more promptly than with the usual technic, by striking gently on the sole of the shoe or on the ball of the bare foot covered with a pleximeter.

He regards joint and periosteum reflexes as essentially muscle-reflex action. This is shown most convincingly in what he calls percussion muscle-excitability (PME); for example, when the knee is raised a little on a cushion, the pleximeter laid across the quadriceps above and struck with the hammer, a reflex contraction follows. It is weaker than that when the tendon is struck because the concussion is spread across the muscle and not lengthwise, but the contraction occurs *en masse* because it is a true reflex contraction. It does not occur therefore in tabes or polyneuritis, while it occurs with greater intensity when the reflexes in general are increased.

At the same time, there is a change in the sound of the stroke on the muscle; in both the tendon and the mass of a reflex-dead muscle, the sound is duller and more doughy than in normal or reflex-exaggerated muscles. When the reflex is lost on one side only, the mere sound will tell whether the normal or the reflex-dead muscle is tapped. It is immaterial whether the concussion of the muscle is produced from above or below, so that nearly all the reflexes can be elicited in three or four different ways. He gives illustrations of the various types described, and states that in health all the larger muscles will respond with reflex action, and the absence of reflex action in several of these muscles should suggest possible organic disease. With exaggerated reflex excitability, there may be crossed reflexes, especially with the pectoral and quadriceps muscles. With the crossed type, the symmetric muscles respond only to stimuli from the sound side. Another important sign is what he calls contrareflex action in case of exaggerated reflexes—the reflex action occurring on tapping the opposite side of the limb.

These signs, he says, afford objective data where hitherto we have been restricted to subjective estimation of abnormally increased or decreased reflex action. The pathognomonic signs are: distinct and extensive percussion muscle-excitability; rare crossed reflexes, as, for instance, of the pectoralis; reflex excitability of otherwise non-excitable muscles, such as the flexors of the toes; and certain clonic phenomena —these all point to organic causes. His "calf phenomenon" has never failed to be more sensitive even than the Babinski, while it has equal diagnostic significance. He gives an illustration of the method of eliciting it, stroking the calf from the back of the knee downward. Independently of each other, Redlich, Gordon and Trömner found that this stroking the back of the calf downward, with some pressure, elicits dorsal flexion of the foot in case of organic increase in the reflexes. In health there is little if any reflex movement. Trömner's experience with this calf phenomenon during the two years since it attracted his attention has confirmed in every respect his first assertions in regard to it (summarized in The Journal, Oct. 21, 1911, p. 1411). It proved extremely useful for the differential diagnosis in a number of cases in which the Oppenheim sign was absent and the Babinski faint and doubtful. He has found that the Babinski can sometimes be made more prominent by pressing with the thumb on the posterior margin of the tibia.

68 *Sterilization of Small Amounts of Drinking Water. (Ein neues Verfahren der Chlorkalksterilisation kleiner Trinkwassermengen.) H. Langer.
69 Trocar-Endoscopy. (Ueber Endoskopie geschlossener Höhlen.) S. Nordentöft.

64. **Arteriosclerosis.**—Hirsch discusses the various theories as to the causes of hardening of the arteries, inclining to the view that both mechanical and chemical factors are involved. He thinks it probable also that the elasticity of the artery walls may be reduced for a time before it is possible to detect histologic change in the tissues.

Loeb has succeeded in inducing experimental lesions in the arteries of dogs, the first time, he thinks, this has been realized in animals other than rabbits. His experiments have demonstrated that lactic acid is concerned in the production of arteriosclerosis. This is significant because during severe muscular work the proportion of lactic acid in the blood may increase from the normal 15 or 30 mgm. to 150 mgm. in 100 gm. of blood. He remarks that this may throw light on the predisposition to disease of persons doing unaccustomed heavy work. He urges special study as to changes in the production of lactic acid in connection with arteriosclerosis. His research has further shown that overstretching of the wall of the artery renders it less resistant to the action of toxins; the resisting power is least at the points where the metabolism differs most from repose metabolism, either from active exertion of the contractile elements or overstretching. He suggests that the difference in the food between that of rabbits and of dogs may explain the greater susceptibility of the former to arteriosclerosis; experiments in this line with dogs are now under way, giving them no meat or other albumin. The results already observed suggest that it may be possible to limit the production of lactic acid in human beings by avoidance of overexertion and by dietetic restrictions, on the one hand, and on the other hand, it may prove possible to annul its toxic action by administering some ammonia-producing substance or the like.

65. **Paroxysmal Tachycardia.**—Kaufman and Popper reported some time ago an interesting case of disturbances from constant abnormal irritability of the supraventricular segment of the heart in a man of 27. Varying conditions of heart-block kept modifying the clinical picture, attacks of paroxysmal tachycardia alternating with irregular heart action and pulse. With the newer methods of examination it was found that the paroxysmal attacks proceeded from Tawara's node, while the arhythmia could be traced to changes in the starting-point of the contractions of the heart, and to varying degrees of sino-auricular block. Under large doses of physostigmin, combined with strophanthus, the attacks of tachycardia became attenuated and ceased, while the subjective and objective symptoms became improved and the heart action passed into another form of arhythmia—the so-called perpetual arhythmia from auricular fibrillation. This form of arhythmia was then kept controlled by atropin; this transformed the arhythmia into a permanently regular pulse of normal frequency. The case confirms anew the efficacy of physostigmin in paroxysmal tachycardia of atrioventricular origin, and it throws light on the close connection between true perpetual arhythmia and certain other forms of arhythmia which are the work of foci of irritability located elsewhere. The case is further an interesting example of the practical therapeutic importance of the study of arhythmias with the sphygmograph and electrocardiogram.

66. **Surgical Tuberculosis.**—Möllers states that including the twelve cases here reported (including three children between 5 and 16) there are now 163 cases of bone and joint tuberculosis on record with careful bacteriologic examination, with the finding of bovine tubercle bacilli in only four cases. That is to say, that in only 2.45 per cent. of 163 cases reported by fifteen different writers were bacilli of the bovine type discovered. This is in marked contrast to Fraser's recent report of 72.72 per cent. of the bovine type in children under 5 and 45 per cent. in older children, in a total of seventy operative cases, all but three in children under 12.

68. **Sterilization of Drinking-Water on Small Scale.**—Langer states that the taste of the water is not impaired by the method he describes and has found extremely effectual in sterilizing even highly contaminated drinking-water. He uses chlorinated lime *(Chlorkalk)* in the proportion of 0.5 gm. to the liter, mixed with an equal amount of common salt to prevent clumping. After ten minutes the taste of the chemicals is removed by neutralizing with sodium percarbonate. The resulting effervescence lasts for about five minutes during which the lime is transformed into an insoluble compound which can then be filtered out. Thus in less than half an hour the badly contaminated water is made palatable and safe to drink. The slight salty taste left he does not regard as disagreeable.

71. **Pyelitis in Children.**—Langstein states that in most cases the pyelitis has been preceded by an acute infectious disease, influenza most often. Whooping-cough, scarlet fever and megacolon are particularly liable to entail pyelocystitis.

He says that the clinical pictures with pyelitis differ more widely in individual cases than with any other disease in the pathology of the child. The toxic form is the most severe in its manifestations; he encountered a number of cases of this kind among breast-fed infants during the heated term. The temperature ran up to 42 C., the weight dropped, and unconsciousness and vomiting were accompanied in some cases with diarrhea. The children had been previously healthy, and at first heat-stroke was assumed, but the urine was found to consist almost entirely of pus. Some of the children recovered. In other cases the symptoms suggested meningitis or pneumonia. The pyelitis was accompanied by jaundice in some cases. The urine was entirely limpid at times; he explains this as the result of obstruction of one ureter so that only the urine from the sound kidney reached the bladder. In some cases the urine was hemorrhagic at first and he thinks that this hemorrhagic early phase has probably in some cases led to mistakes in diagnosis.

Langstein emphasizes the importance of lack of water and lack of nourishment as a factor in the clinical picture of pyelitis. He frequently witnessed a complete transformation follow suddenly on copious intake of water, even when the uremic symptoms were pronounced, and he urges the necessity for watching over the water-supply of infants in such cases. With differentiation in time and proper treatment, 90 per cent. of the children recover. Even with persisting pyuria for a year or more, the general condition can keep fair and the child may thrive comparatively on proper nourishment. On the other hand, years later, contracted kidney may develop as in a case described in which pyelitis in infancy was followed by kidney changes and fatal uremia at 8. This was the only case in his experience in which these conditions followed the pyelitis, but Heubner has encountered a number of such cases. To supply water and nourishing food in adequate amounts may require the use of the stomach tube as the children generally have no appetite. He has found phenyl salicylate (0.6 to 1 gm. daily) more effectual than hexamethylenamin. He suggests that something of the kind should be used systematically in the prevention of pyelitis in the course of scarlet fever or influenza. His experiences with vaccine therapy were not encouraging.

73. **Enuresis in Adults.**—Trembur found by roentgenoscopy and cystoscopy in thirteen cases of nocturnal enuresis in adults that the development of the lower portion of the spinal cord was defective, and that there were signs of malformation or other anomalies. He thinks that there is no doubt that enuresis persisting from childhood is in most cases a manifestation of such myelodysplasia.

88 *Early Diagnosis of Gastric Cancer. (Frühdiagnose des Magenkarzinoms.) F. Leitner.
89 Spirochetes in Progressive Paralysis. H. Geber, L. Benedek and K. Tatar.
90 Biologic Test for Thymus Tissue. (Erfahrungen mit dem Abderhaldenschen Dialysierverfahren—Abbau von Thymusgewebe durch normales Serum.) H. Deutsch.
91 Filter for Radium Rays. R. Bassenge.
92 *Radium in Dermatology. G. Riehl and M. Schramek. Commenced in No. 37.
93 *Geographical Distribution of Cancer. S. Rosenfeld. Commenced in No. 37.

88. **Early Diagnosis of Gastric Cancer.**—Leitner comes to discouraging conclusions as to the possibility of diagnosing incipient cancer in the stomach. The Röhmer-Grafe, Salomon, Oppenheimer and other tests proved in his research to have inherent sources of error which render their findings unreliable.

92. **Radium in Therapeutics.**—Riehl and Schramek conclude here their extensive account of the application of radium at the university dermatology clinic at Vienna. Of the 246 patients, 104 are still under treatment with the radium, sixty-five have been entirely cured (including eleven of the twenty-three cancer cases in which the course has been completed; nine were materially improved, and the condition became aggravated in three). Each one of the nineteen skin diseases represented has some cured cases to its credit, a total of sixty-five cured and seventy-three improved. The only cases in which the radium seemed to do harm were in the three cancer cases mentioned above (the neoplasms were in the cheek) and one case of lymphosarcoma.

93. **Geographical Distribution of Cancer.**—Among the points emphasized by Rosenfeld in his long study of this subject is that the "cancer islands"—the communities where cancer is especially prevalent in a generally cancer-scarce country—should be investigated with special pains, as also the cancer-scarce country around, and then the data thus recorded should be compared point by point. He says of the so-called "cancer houses" that they are generally old buildings with cheaper rents, and the sick and incapacitated naturally gravitate there from their increasing poverty. He thinks that the alleged rarity of cancer in the tropics is more a matter of defective vital statistics than an actual fact. He states that the cancer mortality in Japan (Kioto) ranges from 83 to 95 per hundred thousand inhabitants; at Moscow from 56 to 103; at St. Petersburg from 78 to 98; in southern Italy from 6 to 70; in northern Italy from 51 to 68; in the Netherlands from 75 to 105, while adjoining provinces in Germany have only from 33.5 to 35. It is a curious coincidence, brought out by his figures, that the mortality from cancer is unusually high in the district of Joachimsthal, the source of the radium supply. Another interesting fact noted is that in a country in which cancer is generally prevalent, no districts are found free from cancer—no "cancer-free islands"—while there are numerous "cancer islands" in regions generally free from it. These facts seem especially significant.

95 *Intravenous Injection of Distilled Water in Treatment of Puerperal Sepsis. W. J. Ilkewitsch.

95. **Infusion of Distilled Water in Puerperal Fever.**—Ilkewitsch applied in a number of cases the method of intravenous injection of 1 per thousand silver nitrate solution, introduced by Hume of Baltimore. The results were extremely satisfactory in eighty-three of 138 cases of puerperal fever, but later experience with varying concentrations of the solution convinced him that the distilled water alone, without any drug, answers the purpose equally well. He found in experiments on rabbits that intravenous injection up to 8 or 8.3 c.c. per kilo of body-weight was borne without harm. He has applied this measure in 142 cases of puerperal fever in the last eighteen months, and reports that forty-two patients were cured out of sixty-two with pyemia and septicemia. The communication issues from the maternity at Moscow. It was found that even in the severest cases of septicemia with only 1,500,000 reds, improvement followed the infusion of distilled water.

When the blood-corpuscles increase in number, the outcome is generally favorable but when the number of reds is constantly dropping, uninfluenced by the infusion, the outlook is grave and operative measures are necessary if there is a local process that can be attacked. When the heart, lungs or kidneys are seriously involved, the hemoglobin reduced to 50 per cent. or less, especially in older women, it may be impossible to ward off the fatal outcome by the infusion or any means in our power.

104 *Exaggerated Fear of Anaphylaxis in Serotherapy. A. Guaita.

104. **Fear of Anaphylaxis in Diphtheria.**—Guaita relates a number of instances in which the parents refused to permit the use of antitoxin in diphtheria for fear of anaphylaxis as the child had been injected with antitoxin on some previous occasion. He states that in all his experience and in that of Penna at the contagious disease hospital, Cabrera's at the diphtheria pavillion in the children's hospital, and of others he cites, no instance of anaphylaxis has been encountered although some of the patients had received several injections of antitoxin. He declares that this dread of anaphylaxis is irrational and extremely dangerous. Even at the worst, anaphylaxis is comparatively harmless while the diphtheria is a dangerous enemy. In conclusion, he relates a few examples of fulminating diphtheria, calling on every one to cherish a wholesome dread of this treacherous disease and abandon their fear of the anaphylaxis scarecrow.

105. **Lithiasis in the East Indies.**—Koch states that bladder-stones, kidney-stones and gall-stones are five times as prevalent in the East Indies as in his own country, the Netherlands. The average specific gravity of the urine in Java is 1.023, to 1.016 in the Netherlands. The temperature averages so high that considerable perspiration is almost continuous, and this naturally causes the urine to be abnormally concentrated. In addition to this general factor in lithiasis, the production of concrements seems to be exceptionally high in certain localities, suggesting that the drinking-water must be incriminated. Still another factor in the production of concrements in the urine is the squatting position in urination which prevents complete evacuation of the bladder; Mohammedan males squat to urinate. Koch endorses the advantages of median over lateral lithotomy, especially when the concrements are small or lodged in some rear recess or there is vesical catarrh or the patients are elderly.

106. **Chronic Diarrheas.**—Wijnhausen lays great stress on the importance of macroscopic and microscopic examination of the stools. In chronic diarrhea and catarrhal affections of the bowels, examination of the mucus, food-particles and unchanged bilirubin in the stools will show whether we have to deal with disease in the small or large intestine. He denounces the administration of a laxative, as this increases the serous effusion, thereby furnishing a more favorable culture medium for the growth of the pathogenic bacteria and aggravating the inflammatory process. He insists that both in theory and in practice the so-called intestinal antiseptics are of no value; the bacteria in the intestines will continue to proliferate even after administration of calomel. He advocates a milk diet or diet of dishes made with milk.

In certain cases the diarrhea is the result of disturbances in stomach functioning. It is a well-known fact that persons suffering from achylia gastrica may not display any symptoms on the part of the stomach, but the discovery of connective-tissue fibers in the stools, revealing the lack of normal gastric digestion, points to the defective functioning of the stomach which throws greater work on the intestines and pancreas. Besides this, with gastric achylia the undigested meat-particles from the food form a favorable soil for the growth of bacteria and thereby lead to diarrhea. Gastric atony and stenosis of the pylorus can also cause disturbances resulting in diarrhea. He shows how still other causes may be involved in the production of chronic diarrheas, and how careful study of the stools will disclose the true cause of the trouble and point the way to effectual treatment.

107. **Radium in Ophthalmology.**—Cuperus reports very favorable results from exposures of the eye to radium in treatment of chronic conjunctivitis, iritis and keratitis.

109. **Contributions of the Netherlands to the Progress of Physiology.**—The ninth international congress on physiology was held last month at Groningen in the Netherlands, and the *Tijdschrift* published this special number in honor of the occasion, nearly all the fifteen articles being on physiologic subjects. The *Tijdschrift* also presented each member of the congress with a souvenir-medal bearing a portrait of Donders, and the opening article in this issue is a historical sketch, with portraits of the twelve Dutch scientists who have contributed materially to the progress of physiology. The name of Donders is connected particularly with the discovery of accommodation, refraction and color vision, but he also discovered the chemistry and mechanism of the respiration. Swammerdam, Sylvius, R. de Graaf, Moleschott and Boerhaave are the other most familiar names on the list. Illustrations reproduced from the works of de Graaf, 1641-1673, show dogs with experimental fistulas into the pancreas, salivary glands, etc., the pictures looking as if they might have been taken from a recent work by Pawlow.

115. Marshall's Method for Estimation of Urea in the Urine.—Geselschap has been making comparative tests of different methods in vogue for this purpose, especially the technic recently published by E. K. Marshall (described in The Journal, April 26, 1913, p. 1327) Geselschap found this method extremely reliable while he lauds the simplicity of the technic and the case and promptness of the findings.

125 *Tubal Pregnancy. (Zur Klinik der tubären Schwangerschaft.) I. P. Hartmann.
126 *End-Results of Operative Treatment of Fractures. (Ueber blutige Frakturbehandlung—Osteosynthese.) A. Troell.

125. Tubal Pregnancy.—Hartmann devotes eighty-four pages to a critical review of ninety-three cases of tubal pregnancy; fifty-one of the patients were over 30, and sixty-one had passed through one or more pregnancies, three, six; one patient, ten. In eighteen cases there had been much hemorrhage; in three it had been sudden and profuse, one patient being thus attacked on a sea voyage; one felled suddenly by it on the street, and the third in the hospital where she was being prepared for a vaginal operation. In seven others the anemia developed more gradually, and in the other eight there had been a period of slight attacks of pain long before serious symptoms developed. In nineteen cases there was little if any hemorrhage; in twelve in this group the microscope first explained the nature of the trouble. Vertigo, nausea and vomiting were among the early symptoms in a number of cases. When there is slight hemorrhage into the fetal membranes and the ovum dies and becomes transformed into a mole, the presence of the mole as a rule exposes the patient to no danger, he states. The mole gradually becomes organized and is reabsorbed. This occurs so completely that cases are known in which conception occurred by way of a tube which had at one time been the seat of a tubal pregnancy. He regards curetting as liable to prove dangerous, but says that no harm happened to result although curetting had been done on a mistaken diagnosis in a few cases before the ectopic pregnancy was suspected. In sixteen cases a conservative incision was made in the vagina back of the uterine cervix; this is applicable only when certain that the worst has passed and that we have merely the relics of the process to contend with. Drainage must be kept up for two weeks. Laparotomy is being preferred more and more; it was applied in sixty-six cases; twenty of the women became pregnant again later. Excluding the patients who required removal of the adnexa on both sides, this brings to 40 per cent. the number of women who conceived anew after operative treatment of the tubal pregnancy. When proper treatment is applied at once and no serious relics of the ectopic pregnancy are left, the prospects of conceiving anew are scarcely impaired, while there is comparatively little prospect of pregnancy later when there has been a large hematocele. The proportions in his cases were conception later in 63.3 per cent. of the fourteen women with sudden profuse hemorrhage in the abdominal cavity receiving prompt treatment; 40 per cent. in fifteen with development of a mole with comparatively little bleeding; 36.3 per cent. of eleven with repeated slight hemorrhage into the abdominal cavity, and only 10 per cent. among ten women with very large hematoceles.

126. Operative Treatment of Fractures.—Troell gives ten four-page tables showing the details of the eighty-seven cases of fracture given operative treatment, in which a recent reexamination was possible. The number of fractures thus treated with osteosynthesis was 194 during the years 1885-1910, 6 per cent. of the total fracture cases. The ultimate outcome was found satisfactory in only 83.6 per cent.; it was a trifle better, 89.5 per cent., in the joint cases. The best results were obtained with fracture of the neck of the femur and of the humerus in or just above the condyles. The operation proved most successful when it was done soon after the fracture; the limb must be exercised after a delay of not more than two weeks. Roentgenography shows that deforming arthritis frequently develops in the adjoining joint injured more or less in the trauma causing the fracture; this is the explanation for the mediocre results sometimes obtained. Years may elapse before there are any clinical manifestations on the part of the joint. Static and mechanical disturbances are responsible for the deforming lesion, not the osteosynthesis. Examination of the records of two large insurance companies in Sweden shows that 15 and 18 per cent. of the fracture cases resulted in permanent disability in time. The estimation as to the ultimate functioning of a fractured limb has not much chance of being correct if it is made before the lapse of from two to four years after the injury.

128 *Means to Prevent Operative Pneumothorax. K. H. Giertz.
129 Case of Acute Primary Inflammation of the Cecum. (Om akut primär typhlit.) G. Nyström.
130 *Symptomatology of Paralysis from a Brain Tumor. (Fall af tumor cerebri.) G. Bergmark.
131 Absorption of Ultraviolet Rays by the Lacrymal Secretion. (Om tårvätskans absorption af ultraviolett ljus.) C. Lindahl.
132 Tuberculin-Substance in Cerebrospinal Fluid in Tuberculous Meningitis. G. Bergmark.

128. Means to Prevent Operative Pneumothorax.—Giertz describes a differential-pressure chamber that has been added to the equipment of the Umea hospital. It is modeled on Sauerbruch's chamber but is said to have several important innovations. In connection with this description, Giertz gives illustrations of the other contrivances of the kind in use, including Willy Meyer's at New York. The article is thus a comprehensive review of the achievements to date in the mechanical control of operative pneumothorax, with twenty-five illustrations, two plates and nearly ten pages of bibliography arranged alphabetically for each of the last nine years. The Umea chamber is arranged for the patient to breathe under negative pressure. The chamber is large enough for the patient, operator, two assistants and three nurses with ample space for all; the anesthetist is thus in the same room with the operator. The patient breathes through a mask; the air under negative pressure is brought from without the chamber through a large flexible aluminum tube. Oxygen and an anesthetic can be added to the air in the tube as desired. The patient is otherwise free and there is no binding at the neck as with some of the other arrangements for differential pressure. Of course with a mask there is always a liability to trouble if the patient vomits, and Küttner has reported the death of a patient from acute dilatation of the stomach from air having been forced into it. This is liable to occur with any technic for differential pressure—mask or no mask—except with Meltzer's intratracheal insufflation. Even with this, there is danger of subcutaneous emphysema; Luke has recently reported a case of this following intratracheal anesthesia. The mask technic has the great advantage over insufflation that it does not require preliminary general anesthesia, like the latter. Giertz claims for his apparatus that it applies the principle of negative pressure while combining with it all the advantages of overpressure, and that it requires no special mechanical skill to construct it.

130. Symptomatology of Cerebral Paralysis.—Bergmark removed a sarcoma from the left upper part of the precentral convolution in a man of 57. The sarcoma had been causing jacksonian epilepsy and paresis with signs of pressure on the brain and partial paralysis of the upper arm and shoulder. Its removal was followed by complete paralysis of the right side, sparing only the sternocleidomastoid and the abdominal muscles. Bergmark has found thirteen other cases on record of this partial proximal paralysis of the arm The case is studied from several standpoints, especially the behavior of the diaphragm and the percussion findings on the paralyzed side, the agraphia, etc.

THE RELATION OF PATHOLOGIC PHYSIOLOGY TO INTERNAL MEDICINE *

ALBION WALTER HEWLETT, M.D.
ANN ARBOR, MICH.

For surgery, pathologic anatomy has furnished a basis for both diagnosis and treatment. The tumor or foreign body can be taken out, the inflamed part incised or removed, the obstructed passage dilated or the hollow viscus drained. For internal medicine, pathologic anatomy has been equally important as a fundamental basis in the diagnosis of disease; and it has furnished an exact demonstrable basis for many symptom-complexes. So far as treatment is concerned, however, its direct value is far less evident, for pathologic changes in structure are but rarely influenced by medicine. The clinician schooled in pathologic anatomy is therefore apt to be led into a position of therapeutic nihilism, placing his reliance chiefly on the curative forces of Nature which are to be assisted here and there by medical care and by nursing. This attitude, which was prominent in certain clinical schools during the last century, found its expression in the saying that in Vienna the ideal patient was he whose case was diagnosed by Skoda and whose necropsy was performed by Rokitansky.

At present medical therapy has assumed definite broad lines of development, and optimism in regard to its future generally prevails. Therapeutic advances have been due, in the first place, to the growth of our knowledge of the causes of internal diseases. Whenever possible these causes are to be attacked before they have fastened themselves on the individual, and the science of preventive medicine with its recent but remarkable record of achievement bears witness to the fruitfulness of this line of endeavor. Preventive medicine is rapidly passing into specialized hands, not only as a research and academic subject but in its application to the general health of the community. Yet the use of preventive methods will ever fall within the province of the general practitioner. He must instruct his immediate clientele how best to avoid diseases in general and he must protect them when particular dangers threaten. In chronic affections a knowledge of the cause of the disease may make it possible to limit or to prevent further ravages; in recurrent affections a knowledge of the etiology may make it possible to prevent future attacks. Finally, direct causative therapy has yielded brilliant results in special instances, as in malaria, syphilis, diphtheria and scurvy. At present, however, there are relatively few internal diseases in which a direct causative therapy is successful after the disease has once manifested itself.

If we turn now to that large group of diseases to which no etiologic line of treatment is at present applicable, we find that the advances in therapy, of recent years, have been due largely to the fact that we have learned to recognize clearly that even when the underlying anatomic changes are unknown or inaccessible to treatment, nevertheless much may be done for the patient by correcting so far as is possible the essential functional disturbances which are the immediate causes of his symptoms. The dietetic treatment of diabetes, the dietetic and acid treatment of gastric achlorhydria, the use of digitalis in certain forms of cardiac insufficiency and the restriction of chlorids in special types of edema may be cited as brilliant examples of the effectiveness of medical treatment directed against disturbed functions rather than against anatomic changes or etiologic factors.

Pathologic physiology, the science of disturbed function, has thus become one of the important underlying sciences of medical practice. From the point of view of the clinic, it seeks to explain and to correlate the disturbances in function which occur in patients; and it is the scientific basis of that therapy which is directed against disturbances of function rather than against causes or changes in structure. Although the importance of this subject is now generally recognized, its study and advancement have acquired no definite place in the medical curriculum, in the clinic or in the laboratory. In this paper it is my purpose to emphasize the intimate relation which exists between pathologic physiology and internal medicine, and to discuss some methods whereby the clinical aspects of pathologic physiology may be advanced.

METHODS OF STUDY

Every physiologic process is potentially liable to disturbances; and in its broader aspects pathologic physiology includes the study of all possible functional deviations from the normal. From the point of view of the clinic, however, certain of these deviations assume importance because they are encountered in the course of human diseases. The clinic, therefore, selects its special problems from the general domain of pathologic physiology. It must formulate its problems and it must test the applicability of the general principles of pathologic physiology to the special cases of disturbed function which come within its range of activity.

The problems of pathologic physiology that arise within the clinic may be studied either on patients or on animals. Each method of study has its advantages and each its limitations. The advantage of studies on patients is derived from the fact that we are dealing directly with human disease. Whenever a new method of study in the realm of physiology, biochemistry or

---

* Chairman's Address before the Section on Pathology and Physiology of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

immunology is developed, the question arises as to its *applicability* to patients. If applicable, it must be used in the study of the various diseases encountered in the clinic. Within recent years, for example, the clinical study of the venous pulse and of the electrocardiogram have thrown a flood of light on the diagnosis and treatment of cardiac irregularities; bloodless methods for the estimation of arterial blood-pressure have brought into relief the importance of chronic arterial hypertension; physiologic studies on caloric requirements have profoundly affected our treatment of overnutrition and undernutrition, and chemical examinations of the blood have shed light on the question of nitrogen retention in nephritis, on the nature of gout, and on the disturbed metabolism of diabetes. Eventually such methods of study may become a part of the diagnostic or therapeutic armamentarium of the general or special practitioner. Yet, even though a method for studying patients fails to become directly applicable to routine diagnosis and treatment, it may still prove of great value; for in the light of the new studies, clinical manifestations may take on a new or more definite significance, and our attitude toward disease is always profoundly affected by our interpretation of its manifestations.

Many difficulties are encountered in making accurate physiologic or chemical studies on patients. In all cases we must have due regard for the welfare of the individual, and methods which may be to any degree harmful cannot be used. Then too, pathologic conditions in patients cannot be created; they must be observed as they appear spontaneously in the hospital or outpatient service. That chance favors the mind prepared is nowhere more true than in clinical medicine, in which the mind must be prepared to seize on and to make use of the unexpected and often fleeting manifestations that appear during the course of a disease. Most serious of all perhaps is the fact that it is difficult and often wellnigh impossible to create in the clinic the conditions of an ideal experiment with rigidly controlled variants and with numerous repetitions during which possible errors are eliminated.

It is on account of these difficulties that one must often turn to animal experiments for a solution of clinical problems. Here an attempt is first made to reproduce in animals the disease as it occurs naturally in man. In so doing important etiologic facts may be discovered. When the disease has been produced in animals its manifestations may then be studied with all the accuracy of a biologic experiment. Beyond doubt animal experiments, when applicable, constitute the most satisfactory method for studying a disease, and the results obtained by this method carry with them a certainty that can rarely be attained by studies on patients. The limitations of the animal experiment come, in the first place, from the fact that certain clinical disturbances have not been reproduced in animals; and, in the second, from the fact that even though similar disturbances be reproduced, their exact relationship to the disease of man must be established in each case. It therefore devolves on the clinic to restudy a disease in the light of animal experiments in order to establish the degree to which the conclusions drawn from the experiments are applicable to the natural disease of man.

WORKERS IN PATHOLOGIC PHYSIOLOGY

The field of pathologic physiology has been cultivated alike by physiologists, biochemists, pathologists and clinicians. For the physiologist, deviations from the normal have, as a rule, possessed interest only as they have thrown light on the normal functions of the body, and physiologists have usually refrained from stepping deliberately outside of their domain into the pathologic field. Biochemists, on the other hand, have been more ready to interest themselves in pathologic phenomena, not alone because these assist in the solution of physiologic problems but because their study has seemed worthy of separate pursuit; and metabolic disorders have frequently been studied by biochemists who have had no direct clinical ties. In essence, of course, the subject of pathologic physiology is but a portion of pathology in general; yet pathology in the past has concerned itself mainly with structural changes, and the training of pathologists has often been confined to pathologic anatomy. In addition to this, the immediate routine of the pathologist usually consists in the examination of tissues removed at operation or at necropsy, and he is not forced to study changed function. For these reasons there has been a tendency for pathologists to limit their activities to the field of pathologic anatomy; only in recent years has a strong tendency become evident to return to the physiologic field which was cultivated so earnestly by Cohnheim in the last century.

The clinician, on the other hand, encounters the problems of pathologic physiology at every turn. He is continually called on to interpret and to value the disturbances of function met in his patients and his conduct is deeply influenced by the interpretation which he places on disturbances encountered. From experience he learns to associate certain groups of symptoms with certain other groups. Frequently the anatomic changes which are present offer a fairly simple explanation for the phenomena encountered; but again they give little or no help and he must think in pure terms of disturbed function. To answer the many perplexing questions which arise in the clinic, carefully planned observations on patients or exact experiments on animals must frequently be resorted to.

It has been suggested that the more difficult questions which arise in the clinic should be submitted to the pure medical scientist for answer. The biochemist, for example, might be invited to study the chemical disturbances in cases of diabetes or gout, and the physiologist might study patients with cardiac irregularities, high blood-pressure or disturbed secretion. This general method for studying the problems of internal medicine has its manifest advantages in that it secures the services of experts. At the same time its inherent defects should not be lost sight of. The physiologist or biochemist often has no immediate interest in the problems of the clinic, but prefers to devote himself to the more fundamental aspects of his subject. He is apt to be restive under the clinical limitations which prevent conclusive experiments and often necessitate intermittent work owing to an inability to secure proper material. Finally, the scientific worker often prefers to work in his own laboratory rather than on material which is under the general control of an associate. For these reasons it seems to me that the burden of the work on patients must ever fall on the clinical department itself. The scientist who wishes to test his methods or to solve his problems on patients should be ever welcome to the wards, but the clinician cannot lightly shift the responsibility of his own problems to the shoulders of his scientific brother. Men trained in the methods of physiology and of biologic chemistry are indeed needed in the clinic, but these men should belong essentially to the clinical department and in general they must look for advancement in clinical medicine rather than in the fundamental sciences.

It has also been suggested that whenever the problems of the clinic can be submitted to animal experiment these experiments should be undertaken by men who devote themselves particularly to this line of work. The problems of the infectious diseases have been effectively studied by such specialized workers in bacteriology and kindred subjects; to a lesser extent the problems of pathologic physiology also, so far as these can be studied on animals, are now passing into the hands of workers in experimental medicine or experimental pathology. We cannot but welcome the advent of such departments, which furnish a vigorous stimulus to the study of clinical problems, and teach younger men the scientific aspects of internal medicine; but here again we should not lose sight of the fact that the problems of experimental medicine are derived in the main from the clinic and that the closest interrelation must exist between the two fields. The worker in the clinic should be able at all times to submit his special problems to animal experiments; the results of animal experiments must, moreover, be further tested out on patients in order that conclusions may be rendered valid from the clinical point of view. However much one welcomes the coming of experimental medicine as a separate field of work, its advent cannot be expected to exclude the clinician from the animal laboratory. He more than any other is in a position to be familiar with the exact nature of the problems which arise in the hospital and with the possible applications of animal experiments to medical practice, and he occupies a natural point of vantage in dealing with the problems of pathologic physiology which arise in the clinic.

The position of internal medicine in Germany at the present day is so commanding that it would be well to consider some of the factors which have favored its development in that country. Aside from its organization and methods of academic advancement, one of its striking features is the combined study of theory and practice. Friedrich Müller has pointed out that in contrast to the German school of medicine, the English and American schools have approached clinical medicine much as one would approach trade, which is to be learned by precept and by practice. Valuable as such an attitude may be in the training of medical practitioners, it leaves much to be desired when it comes to the development of medical leaders. For them at least, internal medicine is not simply an application of the healing art; it is also a rapidly growing science. They must be ready, on the one hand, to try all methods of treatment, rational or empirical, proved or doubtful, when called on to alleviate suffering; on the other hand, they must preserve a rigidly scientific attitude when they attempt to interpret clinical phenomena or therapeutic results. Flimsy speculations must be replaced by theory that is based on accurate observation and carefully planned experiments, for no road is too long if the results obtained are decisive. Clinical theory and clinical practice are so intimately bound up in each other that they must advance together; any proposal to divorce the one from the other cannot be regarded as sound in principle.

It must be admitted, however, that the clinician meets difficulties when he attempts a systematic study of the disturbances of function encountered in his patients, or indeed when he attempts to carry out any laborious clinical investigation. These difficulties arise mainly from the absorbing and time-consuming character of his routine duties. He is expected to be a good clinician, expert in the diagnosis and treatment of disease, and the patients entrusted to his care are certainly entitled to the best services that can be rendered. He must often be a teacher, an administrator, and even something of an architect. When to his hospital and academic duties a large private practice is added, little time or energy can be left for carefully planned, systematic investigations which often lead outside the usual routine of medical practice. Exceptional persons will, of course, rise above an unfavorable environment; but experience has shown that in order to have that continuous stream of scientific productiveness which brings rapid and stable advances in our knowledge, the conditions of work must be favorable both to the exceptional person and to the larger number of earnest and capable men who make up the rank and file of scientific investigators. And nowhere, it seems to me, is carefully planned and systematically executed work more needed than in our hospitals. To furnish proper facilities and an efficient organization for such work is one of our pressing problems if we are to attain and hold an international position in the progress of internal medicine.

If carefully conducted research be regarded as a fundamental duty of the medical clinic, it is evident that our clinics must work toward a higher type of organization. Trained assistants must be retained over relatively long periods of time so that they may acquire perfect familiarity with hospital practice and at the same time have time and means at their disposal for investigation. The training acquired during these long years of service should come to be recognized as the best preparation for consultation practice or for an academic career. Such experienced assistants can relieve the clinical chief of much routine work. He in turn must give his best energies to the clinic, and private practice must not become a burden on his time. I think that the proposal to eliminate his private practice altogether would prove an interesting experiment, although one cannot foresee all its far-reaching consequences. To restrict his private practice to the hospital consulting-room and private ward would be a less radical step and would give the clinical head far greater scientific opportunities than he usually enjoys. It would place at his disposal all the machinery of the clinic and would allow him to spend all of his time in his hospital and laboratory.

Time might also be conserved by relieving certain clinicians of the care of the general medical service and by placing under their immediate control only those patients who are suffering from the diseases in which the clinicians are particularly interested. Such a research clinic has its manifest advantages in the way of concentration. In a medical school, however, it could not in itself furnish training in the diagnosis and treatment of the various diseases with which the practitioner must be familiar, and it would have to be supplemented by a more general department of internal medicine. It may be that our medical schools are drifting toward such research clinical departments, but it has always seemed to me that such a separation in the school of the practical training in clinical medicine from its theoretical or research aspects would be unfortunate in many ways and especially for the student who needs not only a familiarity with medicine as a descriptive science but also some acquaintance with the application of exact methods and reasoning to clinical work so that he may experience the difference between speculative and well-founded explanations for disease phenomena.

CONCLUSION

It seems to me that it is the duty of specialists in internal medicine to study the diseases which come within their sphere of activity with all the scientific care and accuracy attainable. Studies in pathologic physiology which belong to this field are often time-consuming and demand special training and equipment; and, with the increasing complexity of medical knowledge, such studies will demand more and more from the clinical staff. To meet these increasing demands it is becoming more and more imperative that the clinical staff should be highly trained and should devote the major part of its energies to the hospital. Only in this way can we hope to attain our full growth in the scientific development of internal medicine.

STUDY OF A CASE OF CONGENITAL HEMOLYTIC JAUNDICE*

ERNEST T. F. RICHARDS, M.D.
Instructor in Medicine, University of Minnesota
AND
WILLIAM C. JOHNSON, M.D.
Instructor in Pathology, University of Minnesota
MINNEAPOLIS

The entire subject of hemolytic jaundice is to-day one especial interest not only because of the rarity of the ndition and its important bearing on obscure diseases the blood and spleen, but also on account of the scant tention which it has received in text-books on medi- ne and the few articles concerning it which have opeared in this country. Notable exceptions to this tter statement are the excellent contributions by Tiles- m and Griffin[1] and Thayer and Morris,[2] in both of hich personal observations on cases are reported and ie history of the disease with its characteristic features ly discussed.

The term "congenital hemolytic jaundice" is applied a rare condition of unknown etiology, characterized a chronic non-obstructive jaundice, splenomegaly, robilinuria, and an anemia, which, dependent on hemol- is, shows, on the one hand, evidence of marked struction of the red blood-cells and, on the other, gns of their continuous active regeneration. A history heredity has been a prominent feature in many cases, which, therefore, the name "familial hemolytic icterus" has been applied. In addition, a closely related type of the disease can be definitely recognized, namely, the acquired. It is also probable that certain border-line cases do occur, as those of Chauffard and Troisier[3] and Aschenheim,[4] which cannot with precision be placed in either group.

The following is the report of a typical case of the "congenital" type which has been under observation for the past year:

History.—Margaret R., aged 23, married, housewife, was admitted to the University Hospital (University of Minnesota) April 5, 1912, complaining of jaundice and a "swelling" in the upper left abdomen. *Adopted at the* age of 4½ months, the patient knows nothing of her parents and has never been able to learn anything concerning them. She was jaundiced when adopted and was said to have been so since birth. Jaundice varying in intensity has persisted ever since, but has not been accompanied by any of the symptoms of biliary intoxication, such as pruritus, hemorrhages and languor. The icterus has not been noticeably increased by muscular exertion or fatigue, or at the menstrual periods. The stools have never been clay-colored at any time so far as the patient knows. Menstrual history is normal. The patient married at 18 years; she had two children; the first was still-born; the second premature (seventh month) and did not live. At the age of 6 years she had a severe attack of inflammation of the joints with fever, and pain in the region of the heart. Between the ages of 1½ and 14 years the patient was subject, at intervals varying from a few months to a year, to attacks of abdominal pain accompanied by vomiting, fever and a decided increase in the jaundice. At such times the stools, so far as she knows, were normal in color. After one of these attacks, at 13 years of age, the patient was seen by a physician who has informed us that at that time the jaundice was marked, there was a distinct anemia and nothing abnormal was detected on examination of the abdomen. Six months later Dr. J. E. Moore performed a cholecystotomy and removed several gall-stones. Following this, the patient believes that she was free from jaundice for a year and a half, after which it again returned. In 1909, after an unusually severe attack of abdominal pain with "chills and fever," her spleen was discovered to be enlarged.

Since that date the patient has had three febrile attacks, each accompanied by an exacerbation of the jaundice and a distinct sense of swelling in the upper left abdomen. These seizures have not been attended, however, by chills or abdominal pain. Stools, as in previous attacks, were never clay-colored. In the last attack before admission (March, 1912), fever ranged as high as 103 to 104 F. for a day or two, the jaundice was intense and the swelling in left abdomen (spleen) was marked.

Physical Examination.—April 5, 1912. The patient is a well-nourished young woman remarkably free from all discomfort. The skin of the entire body and the sclerae are jaundiced a deep orange-yellow. The mucous membranes are somewhat pale. The tongue is clean. Pupillary and other reflexes are active. Intelligence is keen. There is no adenopathy. The heart is 12.5 cm. in width. A soft systolic murmur, only slightly transmitted, is heard at the apex; another, louder than the first, with its maximum intensity in the first left interspace, is heard at the base. Pulse is regular, 80 to 84 per minute. Systolic blood-pressure is 116. Lungs are negative.

The spleen is greatly enlarged. The edge is readily palpable 8 cm. below the costal margin, descending on deep inspiration somewhat beyond the umbilicus. On bimanual palpation it is freely movable, very firm and free from tenderness.

The liver is slightly enlarged; the upper border is at the fourth rib in the mid-clavicular line; the lower border, soft and palpable, is just below the costal margin.

Laboratory Findings.—Urine: Usually highly colored. Traces of albumin present on several occasions. Sugar absent. No indican. Bile negative. Urobilinogen (*paradimethylaminobenzaldehyd*) and urobilin (Schlesinger's; spectroscopic) reactions strong. Microscopically nothing significant.

Stools: Deeply pigmented. No blood, pus, ova or parasites. Corrosive-sublimate test shows hydrobilirubin. No bilirubin.

Blood: Records prior to our own: March 21, *1904, red* blood-corpuscles 3,850,000; white blood-corpuscles *13,250;* hemoglobin, 47 per cent. April and May, *1912,* average count red blood-cells 2,600,000; white blood-cells 7,000 to 9,000; differential, polymorphonuclear *neutrophils* from 50 per cent. to 60 per cent. *and lymphocytes* from 30 per cent. to 40 per cent.

Our own observations on the blood are as follows: March 20, 1913: Red blood-corpuscles 2,600,000; hemoglobin 45 per cent. (Fleischl-Miescher); color index .87; white blood-corpuscles 10,800. Differential count of 500 cells (Wright's stain):

* Read in the Section on Practice of Medicine of the American [illegible] at the Sixty-Fourth Annual Session, held at [illegible] 1913.

* *Because of lack of* space, this article is abbreviated in THE JOURNAL. The complete article appears in the *Transactions of the* Section and in the authors' reprints. A copy of the latter will be sent by the authors on receipt of a stamped addressed envelope.

1. Tileston and Griffin: Am. Jour. Med. Sc., 1910, cxxxix, 847.

2. Thayer and Morris: Bull. Johns Hopkins Hosp., 1911, xxii, 85.

3. Chauffard and Troisier: Bull. et mém. Soc. méd. d. hôp. de Paris, 1908, Series 3, xxv, 41.

4. Aschenheim: Quoted from Türk: Klinische Haematologie, 1912.

Polymorphonuclear neutrophils	66.6%
Lymphocytes	22.0%
Large mononuclears	6.2%
Transitionals	3.0%
Eosinophils	0.6%
Basophils	1.0%
Degenerate forms	0.6%

In April and June similar findings were noted except for a greater number of leukocytes (12,000 and 12,800) and a slightly higher percentage of polymorphonuclear neutrophils. Red cells have constantly manifested microcytosis, anisocytosis, anisochromia and polychromatophilia. Poikilocytosis is slight. Many erythrocytes contain basophil granules; a few show Jolly-bodies. Erythroblasts are very rare. Platelet count (Wright's method), 240,000 per cubic millimeter. Coagulation time, normal.

Osmotic resistance of erythrocytes:

	Initial hemolysis	Complete hemolysis
March 20, 1913, whole blood	0.72 % NaCl	0.46 % NaCl
April 30, 1913, whole blood	0.65 % NaCl	0.40 % NaCl
April 30, 1913, washed corpuscles	0.675% NaCl	0.475% NaCl
June 6, 1913, whole blood	0.70 % NaCl	0.40 % NaCl
June 6, 1913, washed corpuscles	0.80 % NaCl	0.45 % NaCl

Blood-serum: Clear, bright golden yellow, without a trace of hemoglobin. Syllaba's test (modification of Conner and Roper)[11] shows a strong reaction for bilirubin. Urobilin not detected. Patient's washed corpuscles not agglutinated by her own serum. Freezing point of serum — .58 C. Wassermann reaction negative.

Operation.—On May 18, 1912, at the patient's request, a laparotomy was performed. A much shrunken gall-bladder, not containing any calculi, was removed. The patient was discharged from the hospital June 8, 1912.

Present Condition.—June 6, 1913: During the past year the patient has felt remarkably well and carries on her household duties without difficulty. She had been quite free from any of the acute attacks until recently when she went through a rather milder one than usual. The jaundice, as hitherto, has been constant, though at times it is slightly less marked than at others. The spleen is firm and greatly enlarged, the lower edge being 12 cm. below the costal margin. The lower border of the liver is felt a trifle lower than it was a year ago and is also slightly firmer. Patient has been kept constantly on iron, as she finds that if it is discontinued she soon begins to feel somewhat weak.

COMMENT

The study of this case brings out prominently the important features of congenital hemolytic jaundice, which may be classified as (1) jaundice, (2) splenomegaly, (3) diminished osmotic resistance of the erythrocytes, (4) anemia with characteristic blood changes, and (5) urobilinuria.

Jaundice.—Essentially chronic in type, this symptom usually dates from birth or early infancy, but may not appear until later. Pigmentary in character, it does not give rise to any of the symptoms usually ascribed to the presence of bile salts in the blood (itching, bradycardia, progressive emaciation) and is unaccompanied by clay-colored stools or bilirubinuria. In the case under observation the rapid deepening of the icterus during the periods of exacerbation (*crises hémolytiques*) has been a striking feature. At these times, and for a long period after, the color of the skin has been a deep golden yellow. An interesting point is the history of its disappearance during the one and one-half years following cholecystotomy in 1903. This may merely have been one of the periods of intermission so characteristic of the disease, and it is highly probable, in accordance with Chalier's[12] observations, that a subicteric tint was actually present, though unnoticed by the patient.

Splenomegaly.—Particularly during the exacerbations or the so-called "crises" of the disease, splenomegaly may be extreme, the splenic border frequently extending well beyond the median abdominal line. Pain, usually of a colicky nature, may occur in the splenic region, as in the case of Vaquez and Giroux,[13] in which a splenectomy (with fatal outcome) was performed to relieve it. Following the attacks the splenic tumor distinctly subsides but never entirely disappears, usually being left somewhat firmer and larger than before. In our case the increase in size of the spleen during the crises takes place rapidly, to such an extent, in fact, that the patient herself is conscious of its growth.

Diminished Osmotic Resistance of Erythrocytes.—Studies of the globular fragility in conditions of obstructive jaundice, especially in the classical work of Vaquez and Ribierre,[14] had demonstrated an augmentation of resistance to hemolysis by hypotonic salt solution. The method devised by Ribierre[15] for this investigation was simple and ingenious. Making use of it Chauffard investigated the resistance of the corpuscles in three cases of chronic acholuric icterus. In sharp contrast to the findings in obstructive jaundice, these cases presented a markedly diminished resistance. While in normal individuals, according to Chauffard, hemolysis commences at 0.44 per cent. and is complete at 0.36 per cent., in the three cases observed by him the first appearance of hemolysis occurred at 0.62 per cent., 0.66 per cent., and 0.52 per cent., respectively. Widal and his associates later observed diminished corpuscular resistance in acquired types of the disease, bringing out the fact that it was more marked if the corpuscles tested had previously been separated from their plasma. While this discovery applied to congenital as well as acquired hemolytic jaundice it was of particular value in the latter condition, in some cases of which the corpuscular fragility may be so little altered that its increase can be detected only when deplasmatized cells are used. In normal persons little or no difference exists between the fragility of corpuscles in whole blood or when freed from plasma. Throughout the cases of hemolytic jaundice described since the work of Widal and Chauffard, diminished osmotic resistance has appeared to be a practically constant feature. In a few instances, such as those of Lommel[16] (familial) and Mosse[17] (acquired), exception must be made.

In testing the osmotic resistance we have employed a technic rather more precise than Ribierre's. In each of twenty-four small test-tubes (from 7 to 8 mm. in caliber) is placed 1 c.c. of graduated standard solutions of sodium chlorid, differing in strength by 0.025 per cent., and progressively diminishing from 0.85 per cent. to 0.275 per cent. Twenty c.mm. of blood, obtained by puncturing the finger, are measured into each tube (the pipet furnished with the Sahli hemoglobinometer is convenient for this purpose) and immediately thoroughly mixed. A sufficient quantity of blood (from 1 to 2 c.c.) is also collected in citrated salt solution (0.85 per cent. each of sodium chlorid and sodium citrate). After centrifuging and washing twice in 0.85 per cent. salt solution a 50 per cent. suspension is employed in the same way as the whole blood. As soon as the corpuscles have settled to the bottom of the tubes, the degrees of hemolysis are observed by noting the color of the supernatant fluid and the amount of sediment. Ordinarily only the points of initial and complete hemolysis are of importance. The dilution employed (1 to 50) seems to us to be more satisfactory than stronger mixtures in which the concentrations of the solutions are materially altered by the presence of salts in the added blood.

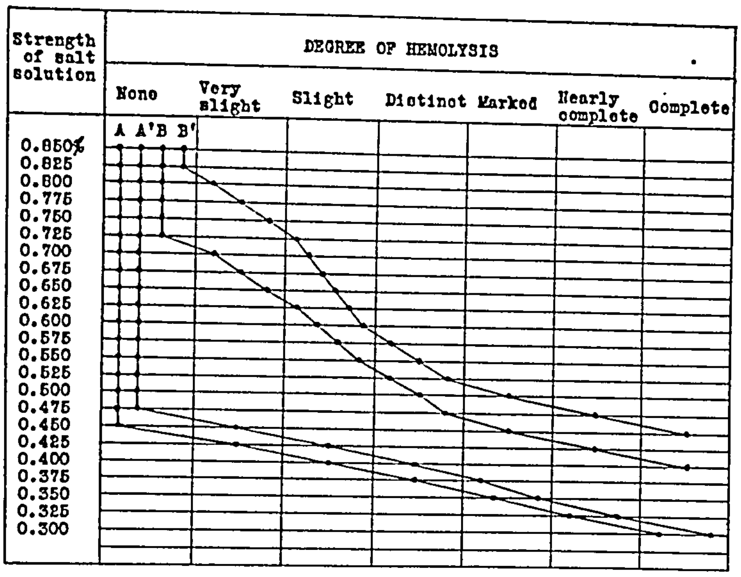

Fig. 1.—Diminished osmotic resistance of erythrocytes of patient with congenital hemolytic jaundice. A, results of testing corpuscles of normal adult (control), whole blood; A', same, washed corpuscles; B, patient's whole blood; B', patient's washed corpuscles. Note especially the higher point at which the patient's corpuscles show initial (very slight) hemolysis. Separating the corpuscles from their plasma has produced little effect in the control but has considerably increased the fragility of the patient's cells.

Anemia with Characteristic Blood Changes.—An anemia of moderate degree is almost invariably present in congenital hemolytic jaundice. The number of red cells is reduced, usually to between three and four million, less frequently below three. Counts below two million are seldom noted. The percentage of hemoglobin is correspondingly reduced, so that the color index remains near 1, but it may be higher or lower. The number of leukocytes appears to vary; most often normal or diminished, at times a slight leukocytosis occurs, as in our own patient. The relative percentages of the varieties of white cells show no constant variation from normal. In exacerbations of the anemia the presence of a few myelocytes is often noted.

While none of the foregoing changes are to be regarded as in any way distinctive, certain morphologic changes in the erythrocytes are of much greater significance. These have been of special interest to us in the study of our case. In comparison with the degree of anemia indicated by the reduced numbers of red cells, the latter show unusual variations in size, with but slight variations in shape. At the same time the average diameter of the corpuscles, as Chauffard noted, is greatly diminished. The latter feature is best brought out by comparison with the normal blood. In Figure 2, A and B are photomicrographs with the same magnification of preparations of blood from a normal individual and our patient respectively. In examination of the latter specimen alone one might easily mistake the large cells in the patient's blood for macrocytes. Comparison, however, shows them to be no larger than the largest cells in the normal blood.

Measurements of 1,000 erythrocytes in thin films of the patient's blood served as the basis for the construction of the curve in Figure 3 (diameters measured to the half micron with Zeiss Messokular No. 3). In this, anisocytosis is evidenced by the extremes in size and by the fact that only half as many erythrocytes (30 per cent.) approximate the mean diameter as in the normal curve (60 per cent.). The average cell (5.8 microns of this patient's blood is a microcyte, since cells of less than 6 microns in diameter are regarded as such. While anisocytosis is so marked in this disease, poikilocytes are few. Not more than 2 per cent. of the cells in our case could be considered sufficiently deformed to come under this head. Among them, however, were many bizarre forms, including small thread-like bodies and dumb-bells. Small bodies from 1 to 2 microns in diameter occasionally noted were considered schistocytes. No less striking than the variations in size are those in the staining qualities of the red cells. These changes are of two types. A moderate degree of polychromatophilia is present, affecting from 2 to 3 per cent. of the cells. Anisochromia, or variation in the depth of staining, is extreme, with all gradations from small, intensely hyperchromatic cells to large pale ones. The pale central depressions are not increased as in chlorosis.

The presence of nucleated red cells has been observed in some cases of hemolytic jaundice. With the degree of anemia manifested in our case it is rather surprising to find so few, only one normoblast being observed in searching several preparations. Other structures, nuclear in nature (sometimes noted in other anemias), are more numerous, namely, the so-called Howell or Jolly bodies (Fig. 4, b). These are small, round, sharply outlined bodies occurring in a few of the larger erythrocytes. They may be centrally located, but are more often eccentric. With Wright's stain these particles appear purple, indicating their chromatin content and nuclear origin.

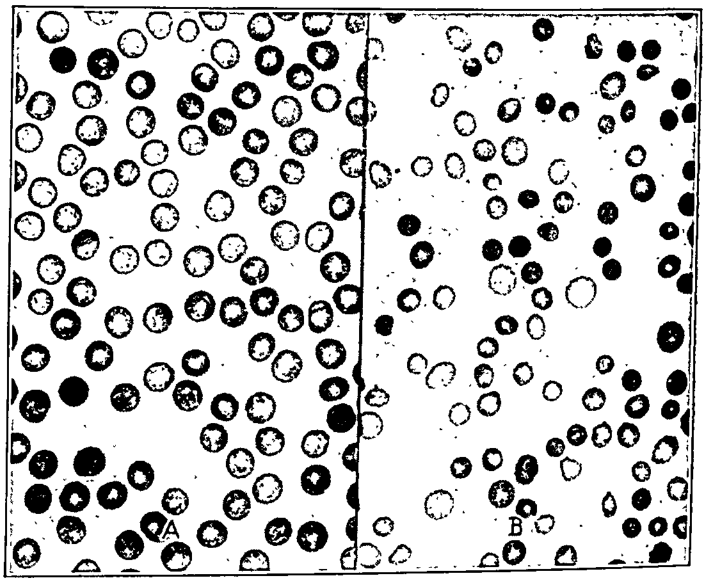

Fig. 2.—Photomicrographs (same magnification) showing blood of patient with congenital hemolytic jaundice (B) in comparison with normal blood (A). The patient's corpuscles show marked variation in size with considerable reduction in the average diameter, the largest erythrocytes being no larger than those of normal blood.

Many of the erythrocytes contain inclusions different in nature from those previously mentioned. These are large, coarse, irregularly shaped basophil granules (Fig. 4 b) which are colored blue with Wright's stain in contrast to the purple of nuclear structures. While one ordinarily has to search before finding a Howell-Jolly body, the cells with basophil granules are noted in nearly every field. These structures generally occur singly; less frequently two or more may be noted in the same cell. The ordinary punctate basophilia, frequently noted in anemias, and especially in lead poisoning, is lacking. Since these observations, Jolly bodies and basophil granules have been mentioned as occurring in a case of hemolytic jaundice (acquired type) by Huber,[19] who states that these findings had not hitherto been described in this disease. As he remarks, the granules may easily be mistaken for a granular precipitate occurring on the surface of the film.

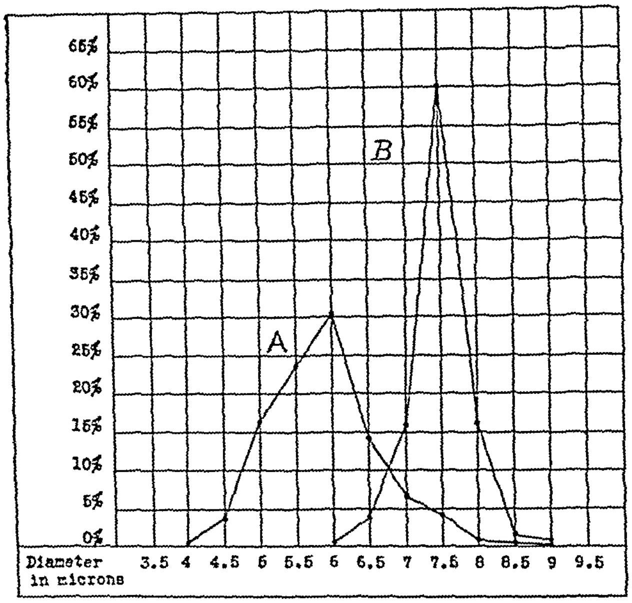

Fig. 3.—Anisocytosis and marked decrease in size of erythrocytes in congenital hemolytic jaundice. A, measurements of patient's corpuscles (average diameter of 1,000 cells 5.8 microns); B, composite curve, for comparison, from two normal adults (average diameter of 500 cells 7.48 microns).

Attention was first directed by Chauffard and Fiessinger[20] to the presence of certain other granular structures in the blood of patients with hemolytic jaundice. When fresh blood is treated with a basic dye by one of the methods of "postvital" staining, some of the red cells show a peculiar network of threads or granules, termed the "substantia granulo-recticulo-filamentosa." These structures, which cannot be demonstrated in fixed smears and are not identical with punctate basophilia, are seldom found in health in more than 1 per cent. of the corpuscles. In various anemias they may reach 10 percent., but are seldom more numerous. Their abundance in cases of hemolytic jaundice establishes a point of considerable diagnostic importance. In most instances percentages of ten to thirty may be noted; in a few, more than one-half of the cells have shown granules. While these basophil structures are not understood, they are generally believed to be of plasmatic rather than nuclear origin, and to correspond to the polychromatophilia of fixed and stained smears. Such a correspondence seems doubtful when such discrepancies in numbers are noted as occurred in our own case, in which less than 5 per cent. of the erythrocytes were distinctly [illegible], but 32 per cent. showed granules by [illegible]. Being generally regarded as representing unripe or immature forms because of their content of basophilic substance, the high precentages of these "granular corpuscles" are evidences of unusually active regeneration of blood. It does not seem unreasonable to credit the granules which we noted in stained smears with the same significance.

We have obtained satisfactory preparations by collecting a few drops of blood in a centrifuge tube containing physiologic salt solution, in which enough brilliant cresyl blue has been dissolved to render the mixture opaque. In half an hour the suspension is centrifuged. A loopful of sediment mixed with a loopful of serum is spread in a thin film on a slide, fixed by heat and mounted in balsam. In the preparation shown in Figure 4 a, 32 per cent. of the cells contained various amounts of granular substance.

The blood-serum in these cases has been found to be markedly hypertonic according to the results of a few investigators, Starkiewicz[21] even reporting a freezing point of — 0.87 C. in one instance. Our own observation has not confirmed this, but slight alteration being noted (— 0.58 C.).

Urobilinuria.—This may be regarded as an index of the amount of hemolysis which is taking place in the body. With excessive hemolysis leading to an increased excretion of bilirubin into the intestine it is natural to expect a corresponding increase in the amount of its reduction product, urobilin, which in McPhedran and Orr's[22] case amounted to six times that in the stools of a normal control. It is possible that, as Huber believes, the liver, already taxed with an increase in its bile-forming function, is unable to modify all the urobilin that is absorbed and hence it is passed into the circulation and excreted in the urine. The usual failure to detect urobilin in the serum of these patients may possibly be explained by faulty methods. Bilirubin, on the other hand, is constantly present in the serum, rarely, if ever, in the urine.

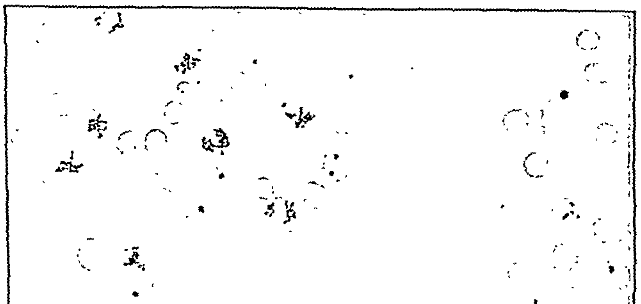

Fig. 4.—Drawings showing features indicating active regeneration of blood in congenital hemolytic jaundice; (a) actual field showing "granular corpuscles" (postvital staining); (b) from fixed specimen (Wright's stain) showing large erythrocyte containing a Howell-Jolly body, and smaller cells with coarse basophil granules.

PATHOGENESIS

The true cause of hemolytic jaundice cannot yet be said to have been established. The characteristic feature of the condition—diminished osmotic resistance of the red blood-cells—is the basis for the belief that the tangible evidences of the disease depend on excessive hemolysis. This view is generally held notwithstanding the fact that Widal and Philibert[24] found that the serum in congenital hemolytic jaundice did not exercise any abnormal hemolytic effect on human red blood-cells. Widal and his school believed that the destruction of the erythrocytes took place in the blood itself, that the bile-pigment formation was hematogenous, and that the splenomegaly was secondary to the enormous work thrown on it by the corpuscular destruction. Minkowski, Chauffard and others, on the other hand, believed that the seat of the excessive hemolysis lay in the spleen. Banti, as a result of the remarkable and lasting effects following splenectomy in his own case and in those of Micheli and Umber, has recently expressed his strong conviction that, in one type at least of hemolytic jaundice, the primary and principal lesion is without doubt in the spleen, its enlargement being due to an excessive increase of its normal function (destruction of erythrocytes). Karsner and Pearce[25] have shown that splenectomy in dogs increases the resistance of erythrocytes, not only to hemolysis by hypotonic salt solution, but also to the action of specific hemolysin.

TREATMENT

Banti[10] reports a permanent and complete cure following splenectomy, in 1903, in a case of acquired hemolytic icterus with diminished osmotic resistance of the red blood-cells and splenomegaly. Excellent results have also followed splenectomy in similar cases of Micheli[29] and Fiori[30] and in the case of Umber's[31] (considered by Banti to have been one of hemolytic jaundice). Roth's[32] patient (familial type) twelve years after splenectomy showed marked improvement, but was not completely cured. In Vaquez and Giroux's case, on the other hand, death followed splenectomy in two days.

Chauffard believed that surgical measures were distinctly contra-indicated in hemolytic jaundice. In many cases, as in our own, the continuous administration of iron has seemed to exert a beneficial effect. The malady in the majority of instances, particularly those of the congenital type, does not seriously interfere with the patient's enjoyment of life and capacity for work. A number, as in Tileston and Griffin's series of "family cholemia," have lived to a ripe age.

In view of these several facts, the wisdom of advocating splenectomy in any given case of hemolytic jaundice without a further knowledge of the true pathology of the affection and a clearer understanding of the functions of the spleen in general must necessarily be left an open question.

914 Lowry Building—313 Eighth Avenue S. E.

ABSTRACT OF DISCUSSION

Dr. W. S. Thayer, Baltimore: I have seen two cases of hemolytic jaundice which Dr. Morris and I reported a year or two ago. The first patient I have heard from repeatedly since. When I first saw her seven years ago she was 16 years of age. She had always been, so far as she knew, a healthy girl, but she as well as her parents noticed that she was slightly yellow, and more yellow at some times than at others. She had the appearance of a normal girl, with good color in her cheeks. On close examination, however, the mucous membranes were seen to be quite pale, and there was this distinct slight jaundice. She had a rather large spleen, coming a hand's breadth below the costal margin. She never had above three million red corpuscles; we did get her at one time up to three million six hundred thousand. Hemoglobin percentage was always between 60 and 70. She improved greatly on long-continued treatment with iodin. Dr. Richards' case shows rather more marked anemia than do congenital cases. Apparently a sharp distinction must be drawn between congenital cases and those which come on later in life; but the question arises, Are both one and the same condition, or is the power of resistance of the red blood-corpuscles something that varies with circumstances? There is reason to believe that the latter is the case from the instances of so-called acquired hemolytic jaundice.

There is much discussion as to the cause of jaundice in these cases. Is it truly a hematogenous jaundice in the sense that it is due to a destruction of the red blood-corpuscles without action of the liver, or shall we believe that there is a true jaundice that does not come from the liver? Hooper and Widal have asserted that in these instances of hepatic jaundice, the jaundice was apparently hematohepatogenous. Curiously enough, they seem to rely particularly on the interesting argument that in these cases there is rarely any slowing of the heart, and seldom any of those signs which we see in ordinary jaundice; therefore it is claimed that those signs which are due to the acids are not present, and we have no excessive coloring matter; but these investigators were unaware of the fact that it had already been definitely shown by King and Stewart that the cause of the slowing of the heart is not bile acids, but that in these cases bile pigments are present, and that under these circumstances the fact of the slowing of the heart is not particularly significant.

Broeger and Hooper have, however, shown definitely that bile coloring matter may arise in the circulation from blood coloring matter. The congenital cases, as a rule, need little treatment, except from the point of view of the cosmetic effect, but the acquired cases may be instances in which treatment is of great importance.

Dr. Joseph L. Miller, Chicago: We have under our observation a case of hemolytic jaundice in a boy of 19 years. He presents all the clinical and blood findings of the case described by Dr. Richards, with this exception, that the resistance of the boy's red blood-corpuscles to salt solution is practically the same as the normal, that is, it hemolyzes at .475. I am convinced, however, that this boy has a case of congenital hemolytic icterus.

There are several cases in the literature of this type in which there is apparently no disturbance of the resistance of the red blood-corpuscles. When we test the resistance of the red blood-corpuscles in a case of icterus of three or four months' duration and find this much increased, that is, that hemolysis takes place less readily than normally, perhaps at .03, and then compare the resistance of the corpuscles in a case of simple icterus with this one of hemolytic origin, we find after all a marked difference in the resistance of the red corpuscles.

About twenty cases of removal of the spleen have, I believe, been reported, and all the patients recovered. Some of these were cases of the congenital hemolytic type. We are trying to prevail on this boy to have his spleen removed.

Dr. R. C. Cabot, Boston: I have had a case like Dr. Miller's in which the resistance of the red cells, apparently increased, was greater than normal; in other respects, it corresponded with his entirely—was a congenital case. I have seen cases just like it in every respect, except that they do not have jaundice.

I have been impressed with the fact that often these persons are not very sick—perhaps not sick at all. I have had difficulty in getting some of them to go into a hospital. They had no idea whatever of consenting to such an operation as the removal of the spleen, because they did not feel sick. In view of the fact that we have no other therapeutics to offer, whatever we have to say in relation to the removal of the spleen is important.

Dr. Ernest T. F. Richards, St. Paul, Minn.: In view of the marked grade of anemia which is present in this case, the question of the acquired type has been ruled out by the history and the existing microcythemia and by the absence of the auto-agglutination phenomenon and of eosinophilia.

Dr. W. C. Johnson, Minneapolis: In a well-developed case of congenital hemolytic jaundice the blood changes are striking and definite. It seems to me that it is nearly as easy to diagnose the condition from a blood-picture of the kind here shown as it is, for example, to diagnose a typical case of pernicious anemia. The special characteristics on which the diagnosis rests seem to depend principally on an extremely active regeneration of the red cells.

IMPORTANCE OF THE TUBERCULIN REACTION IN THE DIAGNOSIS OF EARLY PULMONARY TUBERCULOSIS *

V. C. VAUGHAN, Jr., M.D.
DETROIT

Since the introduction of methods of application of the tuberculin test, the results of which are determined by means of the local inflammatory reaction occurring at the site of application, much discussion has arisen with regard to the best mode of procedure and the practical value of the results obtained.

That the tuberculin reaction represents a phenomenon of sensitization is now generally conceded, and, in order to understand fully its significance, it may be well to consider briefly the mechanism involved in the production of sensitization. Normally, foreign proteins as such do not gain entrance into the body. The most frequent pathologic state in which complex proteins do enter the body as such is represented by the bacterial infections in which the bacterial cells represent highly specialized protein substances growing and multiplying within the body. Thus, when the tubercle bacillus enters the body, a specialized protein substance to which we apply the name tuberculin is produced. According to the theory advanced by Vaughan, in response to the presence of this foreign protein, certain body-cells are stimulated to the production of a special proteolytic ferment, through the action of which a chemical cleavage of the tuberculin occurs with the liberation of a toxic cleavage product, one of the effects of which is a decided irritant action on the tissue with which it comes directly in contact. This local reaction is characterized by hyperemia, increased secretion and, when marked, by the occurrence of minute punctiform hemorrhages, the latter being especially noted when the tissue involved is a mucous membrane or a serous surface. The degree of the inflammatory reaction obtained depends on the amount of the irritant poison which is present at any one time, or perhaps better, on its concentration. This local inflammatory reaction, due to the effects of toxic substance liberated through the action of the specific ferment occurring in the body of the tuberculous on the tuberculin locally applied, forms the basis of the tuberculin test, whether applied to the abraded surface of the skin, the mucous membrane of the conjunctiva or as the percutaneous or intracutaneous reactions.

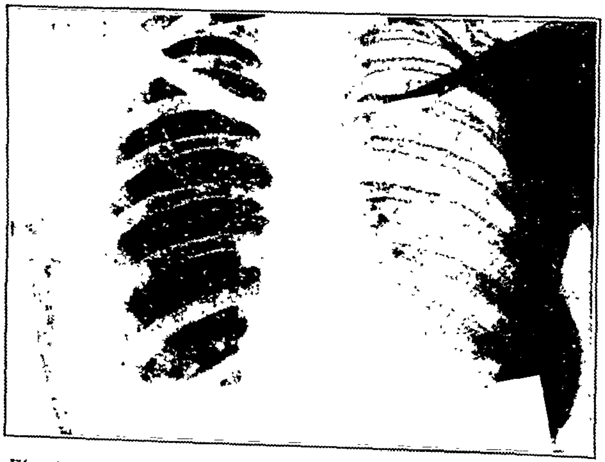

Fig. 1.—Patient 6, L. G., aged 30 years. Eye reaction negative; Secondary reaction positive. Roentgenogram taken sixty months later shows two calcified areas in right lung; otherwise negative.

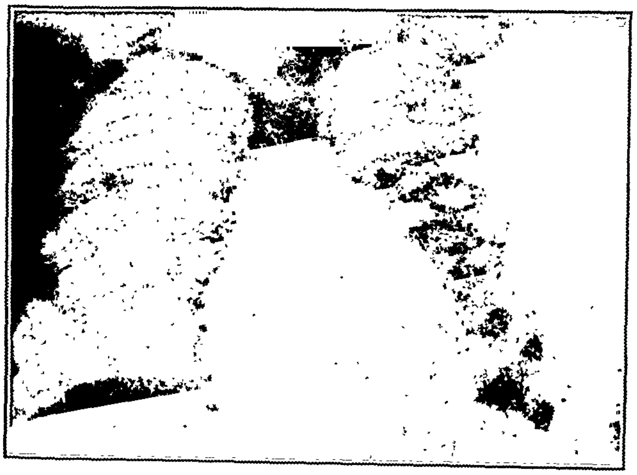

Fig. 2.—Patient 9, T. R., aged 10 years. Eye reaction, negative; secondary reaction, negative. Roentgenogram taken nineteen months later shows no definite signs of tuberculous disease.

That there are limitations to the tuberculin test must be apparent to those who have had much experience with tuberculous disease. As we have seen, a positive test depends on a bodily reaction occurring as the result of tuberculous infection. The tubercle bacillus is, however, essentially parasitic in nature and, as is the case with all true parasites, has adapted itself to live as nearly as possible in harmony with its host. This is evidenced clinically by the fact that tuberculosis is essentially a chronic disease extending over a prolonged period of time and seldom giving rise to symptoms of acute illness. Anatomically the tubercle gives evidence of but slight irritative action of the bacillus on the body-cells, the characteristic giant-cell formation simulating closely the reaction occurring from the presence of an inert foreign body in the tissues. This being the case, it would not be strange if certain persons were found who would fail to develop a special ferment under the influence of tuberculin, and in these no tuberculin reaction would be obtained even though they themselves were the subjects of tuberculous disease. The mechanism of sensitization is an exceedingly delicate one and the important part played by individuality is well evidenced by the varied behavior of patients to sensitiveness following the therapeutic employment of serums.

In view of the before-mentioned facts it would appear that a method of testing the capability of the individual to produce an antituberculin ferment would materially add to any value which might be attributed to the tuberculin test. When the ophthalmic reaction was first introduced it was noted that a suspicious number of persons who failed to react to the first instillation subsequently reacted to a second instillation in the same eye. This brought to mind the possibility of a local sensitization of the conjunctiva, a point which was first suggested by Rosenau and Anderson. In order to test the possibility of such an occurrence tuberculin was instilled into the left eye of an apparently normal person without any noticeable reaction. Ten days later the left eye was reinstilled, and at the same time the first application was made to the right eye. Within four hours a violent inflammatory condition was apparent in the left eye accompanied by purulent exudate, chemosis of the lids and photophobia. The inflammation, however, was superficial in type and rapidly subsided, the reaction having disappeared completely in twenty-four hours. No reaction was apparent in the right eye as the result of the first instillation. This would seem to establish conclusively the local character of the sensitization. Attempts have been made to explain the secondary reaction on the ground of hypersensitiveness from preexisting healed tuberculous lesions, although it is difficult to explain the absolute local character of the sensitization on this ground. As confirmatory evidence of the truth of their theory, these authors refer to the work of Hamburger, who was unable to sensitize the conjunctiva of the newly-born by repeated instillations. I have tried to sensitize the conjunctiva of twenty-seven apparently normal children under one year of age, with the results given in Table 1. From this table it will be seen that I have obtained positive results in 29.2 per cent of the cases.

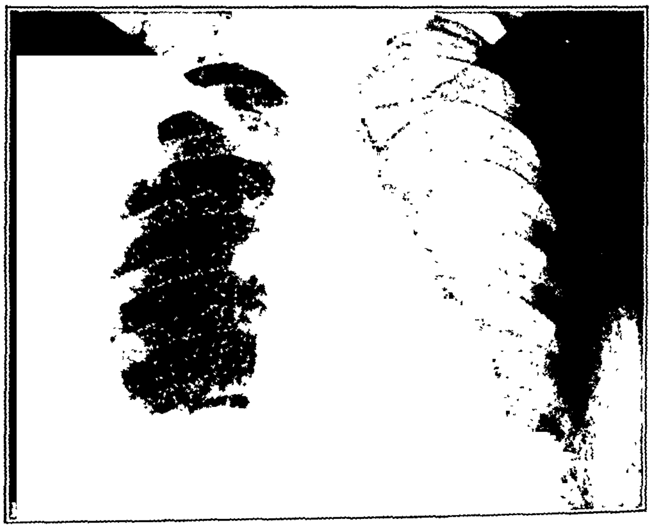

Fig. 5.—Patient 16, S. G., aged 26 years. Eye reaction, negative; secondary reaction, negative. Roentgenogram taken twenty-six months later shows no signs of tuberculous disease.

The conjunctival tuberculin reaction may be absent in tuberculous persons under the following conditions:

1. In rapidly advancing cases, as, for example, acute miliary tuberculosis, acute tuberculous pneumonia and tuberculous meningitis, as well as in the advanced stage of chronic pulmonary tuberculosis.

2. In early pulmonary tuberculosis in persons who are resistant to, or incapable of sensitization to tuberculin.

3. In persons who are the subject of healed pulmonary lesions of slight extent.

I. ABSENCE OF REACTION IN RAPIDLY ADVANCING CASES

In this class of cases if a primary instillation has been negative, I have never obtained a secondary reaction of sensitization following reinstillation in the same eye. The failure to react in these cases is probably due to an overwhelming of the body with tuberculin and a consequent exhaustion of the antituberculin ferment. In this connection it is interesting to note that seven third-stage patients who three years ago reacted positively to the ophthalmic test and in whom the disease has progressively advanced, fail at present to react to instillation in the same eye, with either a primary or secondary reaction. The failure of the test in this class is, however, of no importance with regard to the question of diagnosis.

II. ABSENCE OF REACTION IN EARLY CASES

That a certain percentage of early cases fail to react to the conjunctival test is well known. Thus Wolff-Eisner obtained but 75 per cent. of reactions in his early cases, whereas Baldwin obtained but 67 per cent. and Hamman and Wolman 60 per cent. In a series of 160 cases of early pulmonary tuberculosis I obtained a positive eye reaction in 72 per cent. From these figures it will be seen that the average percentage of positive reactions occurring in early cases is about 68.6 per cent. As has been previously stated, we have in the repeated ophthalmic test a means of determining the capacity of the individual to react to tuberculin. One would expect that the percentage of positive reactions in early cases would correspond approximately to the percentage in normal persons who can be sensitized to tuberculin locally through previous instillation. That there is a rough approximation is seen by the fact that of 109 apparently normal persons who failed to react to the first instillation, sixty-seven, or 63.8 per cent., developed a secondary reaction of sensitization following reinstillation in the same eye. Whether or not a case of early pulmonary tuberculosis will react to the ophthalmic test is determined by the capability of the individual to produce an antituberculin ferment.

TABLE 2.—RESULTS OBTAINED FROM REINSTILLATION IN THIRTY-FIVE CASES

No.	Patient	Age, Yrs.	Eye Reaction	Secondary Reaction	Months Since Test	Present Condition
1.	B. S.	6	—	—	21	Actively tuberculous
2.	W. F.	8	—	—	45	Actively tuberculous
3.	J. H.	15	—	—	46	No signs
4.	H. D.	27	—	+	45	No signs
5.	M. H.	40	—	+	45	No signs

23.	D. S.	31	—	—	21	Actively tuberculous
24.	J. S.	14	—	—	12	Actively tuberculous
25.	M. B.	33	—	—	7	No signs
26.	R. J.	5	—	—	3	Actively tuberculous
27.	H. N.	21	—	—	3	No signs
28.	H. K.	12	—	—	4	Actively tuberculous
29.	R. K.	10	—	—	18	Actively tuberculous
30.	M. M.	18	—	—	8	Actively tuberculous
31.	M. H.	28	—	+	3	No signs
32.	C. V.	28	—	+	60	No signs
33.	H. F.	28	—	+	60	No signs
34.	A. B.	38	—	+	10	No signs
35.	E. M.	10	—	—	12	Actively tuberculous

With this point in mind, when I have failed to obtain a positive reaction in suspicious cases I have always reinstilled, unless some special contra-indication existed. The results obtained in thirty-five cases, which have been observed over a considerable period of time, are embodied in Table 2.

From a consideration of Table 2 it will be seen that of the thirty-five cases, fourteen gave a definite secondary reaction while failing to give a primary tuberculous reaction. Of these patients, who have been under observation for a period of from one month to five years since the application of the test, none at present show any signs suggestive of tuberculous disease. In addition to physical examination, repeated observations with regard to pulse and temperature and inquiry concerning cough or loss in weight, roentgenograms were taken in eight instances during the past week. In all cases except Cases 6 and 20, the plates appeared normal so far as the lungs are concerned. Case 20 showed a slight mottling at the apex which is suggestive of early tuberculous disease. This patient has been under observation for a relatively short time only, although the diseased process, if existing, is certainly inactive at present. Reference to Case 6 will be made later. Case 34 was particularly instructive.

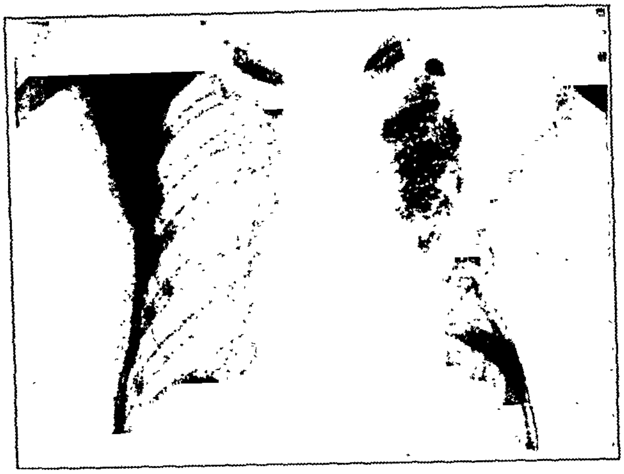

Fig. 6.—Patient 17, M. K., aged 14 years. Eye reaction, negative; secondary reaction, positive. Roentgenogram taken four months later shows no sign of tuberculous disease. Uniform thickening of pleura on the left side due to the previous attack of empyema.

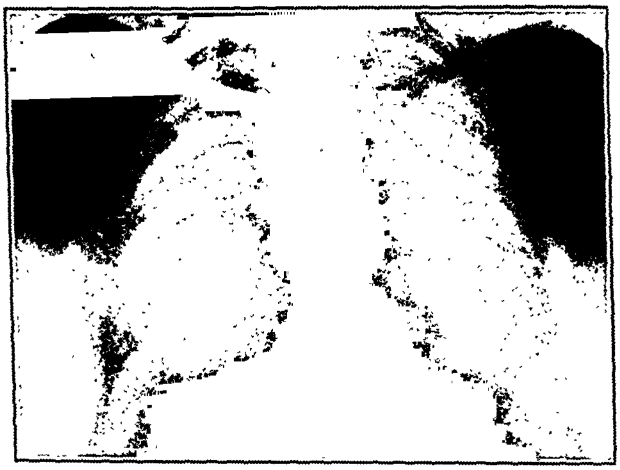

Fig. 7.—Patient 18, A. R., aged 28 years. Eye reaction, negative; secondary reaction, positive. Roentgenogram taken twenty-four months later shows no sign of tuberculous disease.

CASE 34.—The patient, a woman, aged 38, had been under treatment for supposed pulmonary trouble for one year, during which time she had had constantly an afternoon temperature ranging from 99.5 to 100 F. The physical examination failed to reveal any signs in the lungs commensurate with an active process extending over so long a period. The application of the ophthalmic test was followed by a negative result. Ten days later a marked secondary reaction was obtained. The improbability of the failure of the primary reaction in a person who could be so readily sensitized and who was suffering from supposedly active trouble led to grave doubts with regard to the correctness of the original diagnosis. A slight systolic murmur heard at the aortic area suggested the possibility of an aortitis, while the roentgenogram furnished strong confirmatory evidence with regard to this point. A positive Wassermann was obtained and permanent relief was secured under the employment of mercury and the iodids.

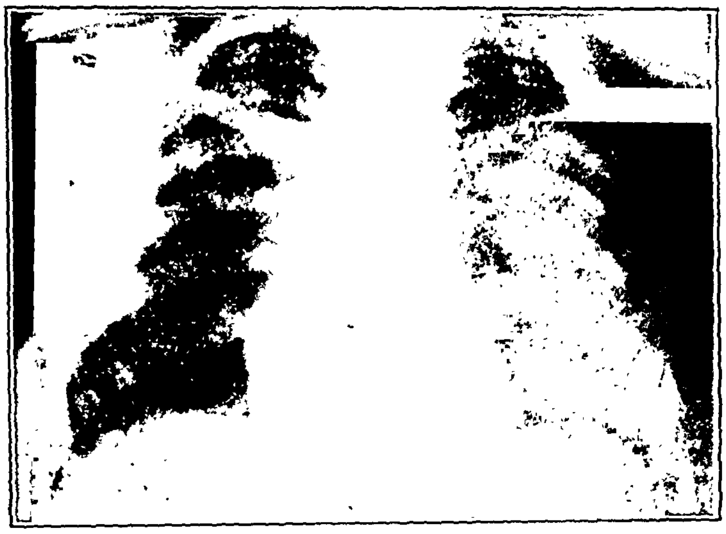

Fig. 8.—Patient 20, H. W., aged 8 years. Eye reaction, negative; secondary reaction, positive. Roentgenogram taken one month later shows slight mottling at apex suggesting very early trouble. Patient, however, shows no physical signs of active trouble, nor is any elevation of temperature ever present.

In the twenty-one suspicious cases which failed to give either a primary or a secondary reaction thirteen patients have since proved to be actively tuberculous. Case 30 is of particular interest.

Case 30.—The patient, aged 18, had presented herself for examination on account of slight cough, loss in weight and an anemic condition. She occasionally had a rise of temperature to 99.5 F. in the afternoon, although this was by no means constant. Examination of the chest showed a prolonged expiratory murmur at the right apex. No râles were heard at any time. The conjunctival test was negative, as was also the reaction for sensitization applied ten days later. This proved that the patient was incapable of sensitization to tuberculin, and consequently the test was of no value as an aid in diagnosis. The roentgenogram taken at this time gave evidence suggestive of trouble at the right apex. Subsequently the patient was informed by another physician that she was not tuberculous since she failed to show any reaction whatever to the von Pirquet skin test. About two months later the patient suffered an acute bronchitis of a week's duration, during which a few tubercle bacilli were found in one specimen of her sputum. They were not demonstrable before this time, nor have they been present since. The patient is at present in a sanatorium for the treatment of pulmonary trouble.

III. ABSENCE OF REACTION IN PERSONS WITH HEALED LESIONS OF SLIGHT EXTENT

In this connection Case 6 is of particular interest.

Case 6.—A young woman, aged 30, presented herself for information with regard to the most desirable sanatorium which she might enter. On questioning, it was ascertained that she had been pronounced tuberculous on the strength of a positive von Pirquet reaction. Since no signs of active trouble could be found, an ophthalmic test was tried with a negative result. Nine days later a distinct reaction of sensitization was obtained in the same eye. We could not believe that a person who could be so well sensitized could be suffering with active disease and still fail to give a primary reaction. The patient was observed over a period of two months, during which she showed no signs whatever of active trouble and at the end of which she was informed that sanatorium treatment was unnecessary. The roentgenogram taken five years later shows two calcified areas beneath the fourth rib on the right side. The positive von Pirquet obtained may have been accounted for in this manner, and it brings forcibly to our mind the exceeding delicacy of this test.

METHOD OF ADMINISTRATION AND TYPES OF REACTION

I have never seen any ill effects as the result of the application of the conjunctival test. In this respect I am in accord with Baldwin and Hamman and other authorities who have employed it extensively. Hamman states that a second instillation should never be made in the same eye owing to the possibility of serious results and the lack of information obtainable from this source. In order to avoid accidents it is essential that the mode of procedure be thoroughly understood and strictly followed. I have always made use of tuberculin tablets, one of which dissolved in 5 minims of water gives a 1 per cent. solution. The container in which the solution is prepared, as well as the eye-dropper, is sterilized by boiling and the boiled water, still hot, is used for dissolving the tablet, the hot water decreasing the toxicity but not sufficiently to interfere with the reaction.

Two distinct types of reaction may be described. The tuberculous or primary reaction which occurs in connection with the first instillation in tuberculous persons, which we may consider as a reaction of infection, consists of a hyperemia of the mucous membrane of the conjunctiva of the lower lid and the inner canthus, occasionally accompanied by the formation of a slight exudate. The reaction is tardy in making its appearance, extends over a considerable period of time, reaches a moderate degree of severity and subsides slowly. The explanation of this is found in the fact that the tuberculin instilled is acted on by the antituberculin ferment present in the fluids of a tuberculous subject. Since no large amount of ferment is active at any given time, the amount of tuberculin split up must be correspondingly small with the liberation of the toxic cleavage product in small amounts over a considerable period of time.

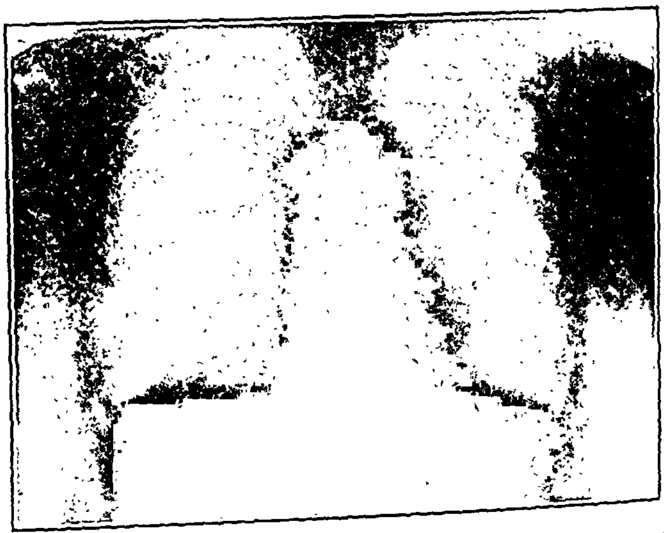

Fig. 9.—Patient 30, M. M., aged 18 years. Eye reaction, negative; secondary reaction, negative. Roentgenogram taken after sensitization test shows tuberculous infiltration at right apex, and also very slight involvement of left apex.

On the other hand, the reaction which occurs as the result of the second instillation in an eye which has failed to respond to a primary test is different in type.

In this instance no reaction follows the first instillation since in the non-tuberculous person no antituberculin ferment is present in the circulating fluid. As a result of the instillation, however, the cells of the conjunctiva develop this ferment which is stored up as a zymogen for future use. A reinstillation at the end of seven days activates this zymogen, the antituberculin ferment attacks the tuberculin instilled and, since present in large amount, liberates the toxic cleavage product at once and in comparatively large amount. For this reason the secondary reaction is characterized by rapid development, high degree of inflammatory reaction and rapid subsidence of symptoms. In applying the sensitization test these facts must be borne in mind. Thus whereas we employ a 1 per cent. solution for the first instillation, we employ a solution of 0.5 per cent. for the second instillation. After the first instillation patients are requested to present themselves for examination on the following day, but if a second instillation has been made the eye is examined at the end of an interval of four hours. At this time in the case of a sensitized reaction a distinct but mild reddening of the conjunctiva will be apparent. The reaction is reported as positive and the eye thoroughly washed with saturated boric acid solution. Under these precautions I have never seen any ill effects, nor, indeed, have I noticed any excessively severe reactions. One would expect that the instillation of stronger solutions of tuberculin into an eye which had previously failed to react to a weak solution might be productive of untoward results. I have always carefully examined the eye before performing the test and have refrained from using it if any inflammatory condition of the conjunctiva was present. It is possible that the phenomena of local sensitization may be demonstrated in other ways. I have of late attempted to apply the same mode of procedure to the nasal mucous membrane, but as yet am unable to report any results.

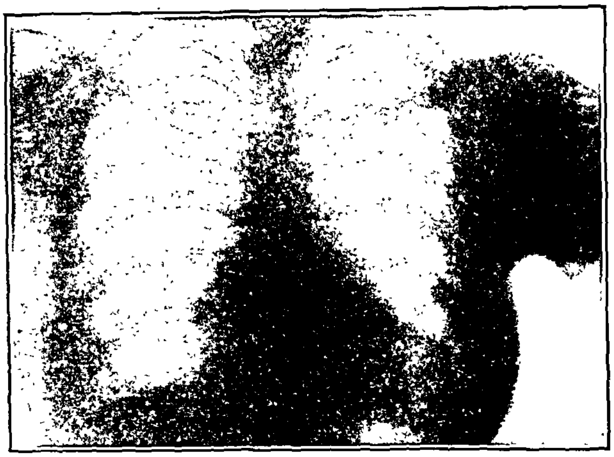

Fig. 10.—Patient 7, G. A., aged 14 years. Eye reaction, negative; secondary reaction, positive. Roentgenogram taken thirty-eight months later shows no sign of tuberculous disease.

CONCLUSIONS

After continued study my conclusions with regard to the value of the ophthalmic reaction in the diagnosis of tuberculous disease which were first advanced in 1909, may be summed up as follows:

1. A positive reaction following the first instillation of tuberculin into the conjunctival sac is strong confirmatory evidence of the existence of tuberculous disease.

2. A negative reaction following the first instillation of tuberculin into the conjunctival sac is of no value in determining the presence or absence of tuberculosis.

3. A secondary reaction obtained in an eye previously unaffected by instillation is strong evidence against the presence of tuberculous disease, at least in an active form.

4. Failure to obtain a secondary reaction in an eye unaffected by previous instillation is of no value in determining the presence or absence of tuberculosis.

Washington Arcade.

ABSTRACT OF DISCUSSION

Dr. Richard C. Cabot, Boston: Despite what Dr. Vaughan has said as to the safety of ophthalmic reaction, the experience of a large number of observers in different countries makes it dangerous to use the reaction. I should advise no one to use it. I have had it used on my own eye, but I would not have it used again.

In a young child the von Pirquet test is important evidence, but it is really of little value in adults; so many adults react because of the presence of latent tuberculosis, which has no practical importance to those persons. Most of us in this room would probably react at this time to the von Pirquet skin test. Sometimes when it is negative it is of value.

Subcutaneous injections of tuberculin are of value when they bring out local reactions at the seat of the disease; for example, they may be of value in showing the nature of the infection in the eye, knee-joint or lymph-nodes.

The Roentgen ray seems to me one of the most important means of evidence we have at present for showing "calcified nodules" in a tuberculous lung, and I use it constantly; but I object to the phrase "the Roentgen ray shows a calcified lung." I have seen calcified lungs demonstrated by a first-class roentgenologist, and when the case came to necropsy there was nothing of the kind there. What we ought to say is, the roentgenogram shows shadows, and nothing but shadows. It never shows pathologic processes. It is for us to interpret what those shadows mean.

Dr. C. L. Minor, Asheville, N. C.: I am extremely glad to hear Dr. Cabot dwell on the unreliability of the von Pirquet test. Patients are being sent away for tuberculosis on the evidence of a positive von Pirquet reaction alone, and yet it has been proved absolutely that after the second year it is valueless, except as a negative test, as Dr. Cabot has pointed out. We cannot emphasize this too strongly and the test should be kept absolutely for use in pediatrics.

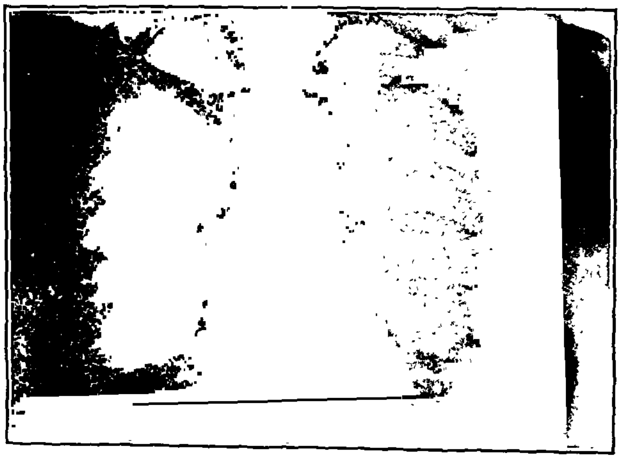

Fig. 11.—Patient 34, A. B., aged 38 years. Eye reaction, negative; secondary reaction, positive. Roentgenogram shows no signs of tuberculosis. Note dilated arch of the aorta. This patient had a specific aortitis.

The Calmette test is undeniably very delicate, but I am not so brave as Dr. Vaughan. I have had one or two violent Calmette reactions that frightened me. It is the danger that patients may lose their eyesight that has held back the use of the Calmette test, delicate as it is. I am well satisfied with the subcutaneous test. If a physician is familiar with

Six months ago I ceased to employ the silk below the knee. In its stead, I have fallen back on a combination of measures that fulfil Lange's aims without drawbacks.

Unfortunately, success in arthrodesis is only a relative matter in children; in its incompleteness, it is sometimes employed.

CAPSULE-TUCKING

More often in cases formerly treated with silk ligament, I use a form of capsule-tucking, to limit the mobility of paralyzed joints. To illustrate, in equinus: I make elliptic skin incisions transverse to the limb over the ankle-joint, retract the tendons and split the ankle-joint capsule midway between its attachments to tibia and astragalus with a full horizontal incision; the two lips of capsule are seized with hemostats and are overlapped sufficiently to correct the toe-drop and sutured with mattress-sutures of very heavy chromicized catgut. Heavy scar tissue forms about the site of these sutures, binding the bones still more firmly together.

In conjunction with joint capsule-tucking, the older measures are used; the dead or weak tendons are shortened; the superficial fascia is overlapped and tucked with mattress-sutures, and the skin brought together, minus the skin-flap removed between the original incision. Almost always some form of tendon work comes in for its due share of consideration (Figs. 1, 2 and 3).

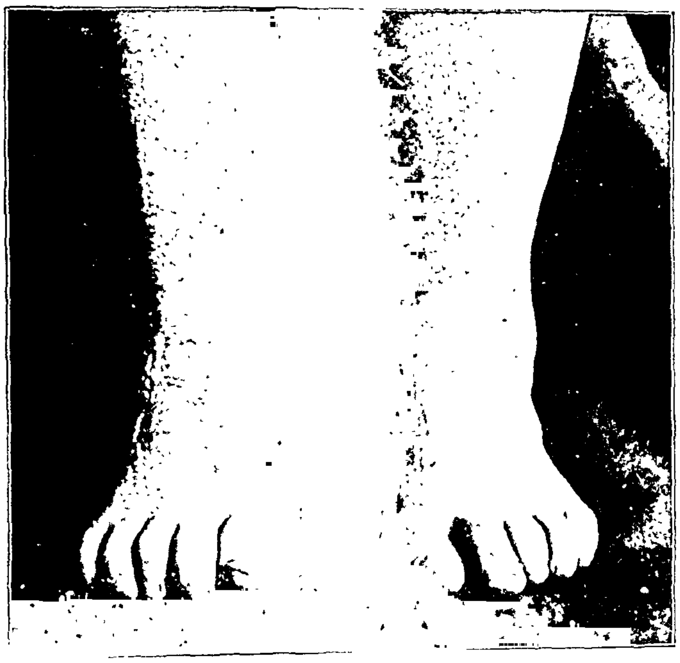

Fig. 3.—Results of joint capsule-tucking in heavy adult, after failure with the silk ligament. Tendon work also used. Considerable motion above right angle. Extreme foot-flexion is shown.

It is only fair to state that on the Pacific coast, life even in childhood is most strenuous. The climate conduces to an active outdoor life the year round. The children in the lower grammar grades are led into football, baseball and track athletics against rival school teams. Boy scouts and fond fathers trail the youngsters over mountains and through difficult forests. Again, the principal industries in our two northwestern states have to do with forestry and fishing—two lines of work that try to the utmost the physical endurance, brawn and limb. Consequently, our patients on discharge fall back to their accustomed activities. A procedure surviving the rack and tear of our section stands the endurance test.

It is my belief that the introduction of a foreign body, such as a strand of silk, into the foot, is not a practical or justifiable measure. The principle underlying Lange's method can more successfully be carried out in treating the leg palsies by modifying the natural structures entering into the joints, gaining fixation thereby, than by the introduction of foreign bodies.

1103 Fidelity Building.

ABSTRACT OF DISCUSSION

Dr. Edwin W. Ryerson, Chicago: Dr. Rich has emphasized a point that is extremely important; that is, that it is inadvisable to leave the knots where the shoes will press against them. You should simply make the loop on the bone, and make the knot away up on the ankle, at the side on which the hole is bored through the tibia. In one or two tendon transplantations in which I left knots in the foot, I had trouble. In a good many other cases, in which I had made knots of large-sized silk, it is only fair to state that they gave no trouble. A piece of silk such as I used, when it becomes covered with fibrous tissue, as I have seen it do in many cases, cannot be any longer, I believe, legitimately considered a foreign body. It is filled with the normal constituents of the human frame and fails to act as a foreign body in so large a proportion of the cases in which I operate that it would not be ordinarily termed a foreign body. I have done a large number of operations of this sort and have seen only three cases in which the silk ligament had to be taken out.

Dr. R. O. Meisenbach, Buffalo, N. Y.: I should like to ask Dr. Rich whether or not he uses paraffined silk.

Dr. Edward A. Rich, Tacoma, Wash.: The question of the use of the silk ligament is not, as yet, a settled one. Whether we shall ultimately be inserting heavy silk strands into the neighborhood of joints is in my opinion doubtful. The point I wish to make emphasizes the fact that in the West, under Western conditions—which may be different from conditions elsewhere—the silk does not give satisfaction in the lower extremity.

In the earlier work with silk I used the plain, twisted silk, twice sterilized; however, in the last two-thirds of the cases I have turned to the paraffined silk and believe that it is preferable.

Dr. Meisenbach: Why did you change?

Dr. Rich: We changed from the plain to the paraffined silk because Lange advised it, and because the plain silk had been causing too much seepage from the periosteal and bony attachments. Most of our failures have been attributable to one of two causes; first from the wick-like drainage of the plain silk, and second from external irritation.

CLINICAL AND LABORATORY SALVARSAN RELAPSES AND THEIR REMEDY

A SEROLOGIC STUDY OF SIX HUNDRED FIFTY-ONE CASES COVERING NINE HUNDRED FIFTY-TWO INTRAVENOUS ADMINISTRATIONS AND THREE THOUSAND THREE HUNDRED FOUR WASSERMANN EXAMINATIONS *

M. L. HEIDINGSFELD, Ph.B., M.D.
Professor of Dermatology, Ohio-Miami Medical College of the University of Cincinnati; Dermatologist of the Cincinnati General Hospital
CINCINNATI

Sufficient time has already elapsed and the number of cases has been amply large to permit a retrospective analysis of the salvarsan treatment of syphilis and an estimation of its true and relative worth. Despite the fact that it fails, from both a clinical and laboratory point of view, to effect a permanent cure here and there, it is safe to assume at present that it has clearly demonstrated itself to be the sovereign remedy for the succes-

* Read in the Section on Genito-Urinary Diseases of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

ful treatment of the various stages of syphilis and has definitely acquired an indispensable place in this important field of therapy. It is no longer necessary to determine whether it is a useful or a useless remedy, whether its results are efficacious or futile, its effects good or bad, or whether it should or should not be administered in all well-defined cases of active syphilis. There is scarcely a person of even moderate experience who will not concede, without bias or prejudice, its great positive worth in these and many other directions. The salvarsan problem of to-day is no longer a question of whether it should or should not be administered, but (1) what its untoward results are and how they can be successfully obviated, (2) to what degree its curative properties can and should be carried, (3) to what extent its action must be supplemented by other agents and (4) what plan of treatment subserves its purpose best.

Salvarsan results can be conveniently grouped into two large classes, namely, cases of syphilis in which clinical symptoms have remained in abeyance for a year or more, with persistent negative Wassermanns, and those which have shown relapses of a clinical or laboratory type or have failed to proceed to an apparent recovery from either a clinical or laboratory point of view. The conversion of the latter to the former is the question of chief absorbing interest at present, and the successful therapeusis of syphilis will not be satisfactorily elucidated until this goal is reached.

METHOD OF ADMINISTRATION AND TREATMENT

The attempt to establish fixed rules for the successful treatment of syphilis from a salvarsan or any other point of view has ever been and probably will ever remain an exceedingly difficult undertaking. There is so much variation in technical ideas and disparity in method of treatment, control and individual results that it will require a long period of careful observation, investigation and study before a fair degree of unanimity of opinion can be successfully attained. There are, however, a few fundamental principles in reference to salvarsan which have received general, but not their fully deserved universal, recognition. The generally practiced intravenous administration of salvarsan is almost universally conceded to be the most efficient method of neosalvarsan treatment. It can be performed, under proper technical precautions, without untoward incident and danger, in ambulatory practice and in threatening complications of somewhat unfavorable character. It is of utmost importance that every step of the operation be attended with painstaking surgical asepsis. All vessels and paraphernalia should be surgically clean and freshly sterilized. It is essential that the water used for cleansing and dissolving purposes should be freshly distilled and surgically clean. Distilled water from druggists and mineral-supply houses must be questionable and unsafe if allowed to stand longer than twenty-four hours. Ehrlich and others have clearly established that many of the untoward results from salvarsan and neosalvarsan in the past have been the result of improper technic and, most notably, the use of impure water.

DOSAGE

Opinion remains divided, with no hope of an early adjustment, regarding salvarsan dosage in syphilis. For the most part, one of two methods is employed, large and oft-repeated doses during the early stages of treatment, in order to obtain theoretically a *dosis sterilisans magna*, or relatively smaller or less frequently repeated dosage. The former attains more generally in Europe, the latter possibly more in this country. It is needless to state that the early ideals of Ehrlich regarding a *dosis sterilisans magna* have not been attained in the vast majority of cases. It is possibly true that a single administration often effects an apparent cure, most notably in early initial lesions, before general infection has become established or of long-standing character. During my earliest experience with salvarsan I was inclined toward large and oft-repeated dosage. Not noting any material improvement or favorable change from a clinical and laboratory point of view in the refractory cases, even when salvarsan was administered in inordinate oft-repeated dosage, I promptly pursued a more conservative policy in regard to salvarsan administration in all cases. Partly from observations personally gleaned abroad and partly at the personal solicitation of Ehrlich, I underwent a change of sentiment for the time being and pushed the treatment beyond the clinical and Wassermann requirements in order to do too much rather than too little and to play the game on the safe side. My results conformed to the impressions obtained from previous experience, namely, that clinical and laboratory relapses were not thereby more favorably circumvented and that persistently positive Wassermanns could not be materially changed by such a procedure. If one or two salvarsan administrations failed to effect the desired result, a dozen closely repeated would not change the situation, even if they were otherwise well tolerated. I found it necessary in this class of cases to resort to adjuvants of a different character, and these form the basis for the presentation of this paper. Cases of laboratory or clinical relapse which were once favorably influenced by salvarsan treatment were usually promptly benefited when treatment was again repeated. Aside from this particular class, however, frequently repeated salvarsan possessed, in and of itself, little significance. Salvarsan, however, repeated after months of intermission, has often effected the desired result.

THE WASSERMANN REACTION

I wish merely to reiterate what has been expressed on former occasions relative to the importance and significance of a careful Wassermann complement-fixation control over all cases of syphilis. To treat a case of syphilis without this aid is virtually attempting to sail a vessel without the directing aid of compass and rudder—mere guesswork. Without its aid I should lack assurance whether my case was progressing favorably or unfavorably, as to whether or not some other therapeutic agent should be called into play, whether the prognosis augured favorably or unfavorably, whether early marriage should be encouraged or discouraged. A careful and properly made complement-fixation test gives all this wealth of information, without which the treatment of the case must remain more or less empirical and tentative in character. I am firmly of the opinion that no case of syphilis can be intelligently and satisfactorily treated without some such form of control. When personally supervised, the Wassermann possesses the greatest degree of scientific interest, and the progress of the case under intelligent interpretation can usually be measured with almost mathematical exactness. The Wassermann occupies, in my personal estimation, a place second to none, not even salvarsan, in the successful treatment of syphilis.

SEROLOGIC ANALYSIS

In 651 cases 3304 Wassermann examinations were made, and salvarsan was administered 952 times from Dec. 25, 1910, to June 1, 1913. The administrations were made in ambulatory private practice, during the consultation hour, and not a single administration was attended by any incident of untoward character. The initial dosage was almost uniformly 0.6 gm. of salvarsan and 0.9 or 0.6 gm. of neosalvarsan; if neosalvarsan was repeated within from thirty to sixty days, 0.3 gm. was usually administered, unless persistent lesions or an unchanged and strongly positive Wassermann indicated otherwise. A Wassermann examination was made prior to the initial administration and was repeated every thirty days, until the blood became negative. When the fixation test remained negative two successive times, the examination was repeated in sixty days; if then negative, in ninety days, and then at intervals of six, nine and twelve months, according to the special indications of the case. It is needless to state that the complement-fixation examinations could not be systematically pursued in all the cases. Some of the patients absented themselves voluntarily; others, owing to foreign residence, enforced absence, delinquency, etc., involuntarily. The vast majority, however, reported regularly and the serologic study could be more carefully, consistently and intelligently carried on than is permissible in clinical and hospital practice. In only 209 cases of the 651 treated was there a record of but one Wassermann examination, and a fair percentage of these were cases that had received salvarsan for a period of less than ninety days. Deducting the 209 cases which were observed less than ninety days, or could not be intelligently followed for the reason of only one Wassermann examination, in 339 out of a total of 442 cases, or 77 per cent., the patients proceeded to recovery from a combined clinical and laboratory point of view, as a result of one or more administration of salvarsan. No other adjuvant was employed, although 276 cases of somewhat long standing received some form of antisyphilitic treatment prior to the administration of salvarsan. The majority of these, however, showed clinical relapses or positive Wassermanns at the time salvarsan was first administered.

Of the 103 cases, or 23 per cent., of salvarsan failures, nine received no additional attention. Of the remaining 94 cases, 13 proceeded to clinical and laboratory recovery with the aid of mercurials and 23 with the aid of atoxyl and sodium cacodylate; 21 have been observed comparatively too short a time to pass definite judgment. Twenty-two cases have apparently failed, from at least a laboratory point of view, with all methods of treatment. Summarized, in 50 per cent. of salvarsan failures the cases have proceeded to complete clinical and laboratory recovery when the treatment was supplemented by other measures.

In 371 cases, for the most part old and long-standing infections, some form of previous mercurial treatment has been received. Of these, 230 cases proceeded to recovery and 95 could not be intelligently followed. In other words, 83.5 per cent. proceeded to absolute recovery from a clinical and laboratory point of view. This is of striking interest, as it shows that more cases (83 per cent.) proceeded to salvarsan recovery when previously treated with mercury, than those cases (61 per cent.) which had received no previous mercurial treatment. This fact must possess great clinical significance. It apparently indicates that previous mercurial treatment favorably influences syphilis for salvarsan treatment. It may be, however, that the percentage of recovery is higher in the cases previously treated with mercury for two apparent reasons: (1) A large percentage of these cases were of rather long standing, with weak positive, negative or almost negative Wassermanns. Some possessed a dubious history, enveloped in greater obscurity by a too early administered mercurial treatment. The cases not previously treated with mercurials were, almost without exception, comparatively recent infections personally observed in which present-day methods of greater accuracy—the dark-field microscope and the Wassermann complement-fixation test—eliminated sources of possible error. Furthermore, the previously treated cases were of longer standing, and this, in and of itself, is a favorable feature, inasmuch as a large number of cases gradually proceed toward spontaneous recovery from both clinical and laboratory point of view, without the aid of other measures, in due course of time.

It is evident from this that salvarsan failed to effect a satisfactory result, from a clinical and a complement-fixation point of view, in 23 per cent. of the cases treated, and salvarsan aided by other measures in about 12 per cent. I do not wish to imply that these cases have been abject failures. On the contrary, I am firmly of the opinion that the administration of salvarsan has been attended by marked benefit and material improvement in all cases. Some of these "failures" were in cases which presented ravages of a severe and malignant type; cases which were rapidly proceeding to an unfavorable termination in spite of the free and intelligent use of mercurials, iodids and general old-line treatment. The failure has been largely, almost exclusively, of laboratory character and, from an objective clinical point of view, they would have readily passed muster as cures. These patients as a class showed no clinical manifestations, and their general state of health and well-being was, for the greater part, excellent. The persistent strong positive Wassermann, however, gave evidence that these patients were not cured, and that if further treatment were definitely intermitted, they would eventually present clinical manifestations of a relapsing type.

Hospital and dispensary practice bears abundant evidence that clinical as well as laboratory relapses occur in insufficiently treated cases. The treatment of syphilis cannot be considered eminently successful unless the patient is thoroughly insured against relapse. It must be thoroughly eradicated, if the patient is to remain pleased and satisfied with the attention, and the physician is to do full justice and credit to himself. In syphilis a half-cure is virtually no cure. False assurance can do harm, not only to the patient, but also to his environments. To effect a cure here and there requires no particular skill and attainment and should bring no credit to the physician who essays it. Nature doubtless effects that much unassisted. It is some credit to improve on Nature and to increase her percentage of favorable results. It is a matter of extreme discredit, however, not to recognize the uncured patients, and not to labor for their ultimate recovery, if such possibilities are within our province and are not accepted. The cases of persistent positive Wassermanns, in spite of prolonged intelligent attention, are doubtless the ones which present the greatest menace. These are usually the cases in which the disease is constantly making slow and insidious ravage without external evidence or manifestation. These are the cases which ultimately show the irreparable and distressing invasions on the cerebral, spinal and circulatory systems. It is therefore the 23 per cent. of salvarsan failures with which the profession must now be seriously engrossed, for it is unpardonable to allow one in every four patients with syphilis to incur this unnecessary risk, if there are satisfactory and intelligent methods of circumventing it.

For the past year or more I have endeavored to seek some satisfactory method for the conversion of the 23 per cent. Wassermann positives to negatives, in cases which have successfully resisted three or more salvarsan administrations. In the beginning I employed massive intravenous administrations of mercury oxycyanid and mercury bichlorid, from 100 to 200 gm. of a 1:1,000 solution. The results, from the point of view of complement-fixation, were encouraging, but gastro-intestinal disturbances and localized obliterating phlebitis discouraged my effort in this particular direction. Since then I have employed a 10 per cent. solution of sodium cacodylate and atoxyl, with more encouraging results. Sodium cacodylate has proved itself to be the more efficacious and reliable of the two. Twenty-two cases of a total of fifty which could be intelligently followed proceeded from Wassermann positive to Wassermann negative with deep muscular injections of sodium cacodylate. Many of the cases were not favorably influenced from a Wassermann point of view, and a few retrograded from weak positive to strong positive. It is difficult to conjecture whether this retrogressive change was incident to the cacodylate or to the natural causes of syphilis. The injections were made twice weekly for from thirty to sixty days. If the Wassermann was negative in thirty days, it was administered once weekly. The cacodylate injections were never continued longer than sixty days and not repeated under intervals of two or three months. They were well tolerated in all cases. Salvarsan was repeated every three or four months in all persistently positive cases; a number of persistently positive cases which successfully resisted salvarsan, cacodylate and other measures for several years have eventually become weak positive or Wassermann negative. I am encouraged to believe that all cases, with intelligent, persistent attention, give fair promise of eventually becoming Wassermann negative. Only five cases in my experience have relapsed to a Wassermann positive after being negative for one full year. It is probably needless to add that general tonic treatment was not omitted and that dietary and other regimen was properly imposed. Alcohol was absolutely interdicted in all cases until the Wassermann remained absolutely negative for a period of ninety days; the cases in which this was not observed and those in which the patients were previously addicted to the inordinate use of alcohol fared worse as a class. Relatively few patients showed appreciable material improvement when the treatment was supplemented by inunctions or deep muscular mercurial injections.

This paper is based entirely on my own impressions, gleaned from the careful study of cases under my personal observation and control in private practice. It has been my endeavor to exclude carefully any impression from the experience of others to confrères, which may have reached me directly or indirectly through the literature. I have been actuated to do this chiefly for the reason that the literature on the subject is much at variance with itself. It is an easy matter to find confirmation or rejection, as the case may be, for any statement for or against the use of salvarsan. For these evident reasons the literature has not been consulted and all references have been carefully excluded.

I wish to reiterate what I have already stated on former occasions, namely, that the Wassermann is the oracle and mentor of syphilis diagnosis and therapeusis. The diagnosis and treatment of syphilis without Wassermann control and other specialized aid must be unscientific and, in a large degree, unsatisfactory in character. Salvarsan, though not an unfailing remedy, is by far the most effective present-day agent which we possess for the treatment of syphilis. It effects an apparent clinical and laboratory cure in about 77 per cent. of the cases treated. A large proportion of the remaining 23 per cent. of cases, with the aid of sodium cacodylate and other measures give every promise of proceeding to a negative Wassermann and absolute clinical cure in due course of time.

19 West Seventh Street.

AN EXPERIMENTAL STUDY OF THE ANTISEPTIC VALUE IN THE URINE OF THE INTERNAL USE OF HEXAMETHYLENAMIN *

FRANK HINMAN, A.B., M.D.
Assistant Resident Surgeon, Johns Hopkins Hospital
BALTIMORE

Since 1895, when Nicolaier[1] first demonstrated formaldehyd in the urine as a decomposition product of hexamethylenamin, the use of hexamethylenamin as a urinary antiseptic has been almost universal. Churchman[2] indicated in 1906 its antiseptic value with the conclusion that its effects in the urine are expressed in an inhibition of bacterial development rather than in a destruction of bacterial life. Nothing more definite appeared until last year, when Burnam[3] upset our ideas somewhat by stating that on the customary doses of from 5 to 10 grains three times a day not more than two patients out of ten would show any decomposition of the drug into formaldehyd at all, while only 60 per cent. would show it on a dosage of from 20 to 30 grains every four hours. These findings were quickly confirmed by L'Esperance[4] and Jenness,[5] the former finding 52 per cent. formaldehyd-containing urines in 250 cases, and the latter only 47.2 per cent. in 200 cases. Smith[6] published observations on fifty cases, in only one of which did he fail to find formaldehyd.

No attempt was made by any of these investigators to determine the quantity of formaldehyd put out in a series of cases, nor have the factors influencing the conversion of the drug into formaldehyd been definitely established, although it has been known for some time that hexamethylenamin itself has no antiseptic power, and that it is only through its being converted into formaldehyd that any antiseptic benefit can be derived from its use.

The present study attempts to indicate the quantity of formaldehyd, and, therefore, its true antiseptic value,

in the urine of patients receiving 15 grains of hexamethylenamin three times a day after meals, and to determine the important factors influencing this quantitative output.

The results for the convenience of better consideration may be divided into the following parts:

1. The germicidal and antiseptic values of formaldehyd.
2. Chemical tests for formaldehyd in the urine, with the report of a simple method of quantitative estimation by a modification of the Rimini test.
3. The antiseptic value to the urinary system of hexamethylenamin by mouth.
4. A consideration of the important factors influencing this value.
5. Comparative values of some of the allied hexamethylenamin compounds.

THE GERMICIDAL AND ANTISEPTIC VALUES OF FORMALDEHYD

The bacteriologic study of formaldehyd divides itself naturally into that showing germicidal power, and into that showing antiseptic power. By germicidal is now generally understood a complete death of the organism; by antiseptic, an inhibition of growth for a variable time while exposed to the action of the drug, but with the ability to resume activity on being removed to a favorable environment.

A review of the work of other investigators, of which there have been a great many, and my own experiments, indicate that formaldehyd is a weak and a relatively slow germicide, but that even in high dilutions it exerts a powerful inhibitory influence to bacterial development. This power of inhibition varies with the different organisms studied. The staphylococci, and the typhoid and colon bacilli are the most resistant, the *Bacillus pyocyaneus* and streptococci are next, while the proteus group, the diphtheria and pseudodiphtheria bacilli, *B. subtilis* and *B. dysenteriae* are less resistant to its action. A dilution of formaldehyd of about 1:16,000 or stronger is totally inhibitory to the growth of *B. typhosus* for twenty-four hours, and a dilution of 1:6,000 is completely germicidal at the end of that time. A dilution of 1:30,000 definitely restrains the growth of the organism, but a dilution of 1:40,000 has no apparent effect, although, if the results are shown by means of plating and a systematic bacterial count, there will be a slight diminution in the count as compared to a control in broth.

In order that formaldehyd in the urine may be of clinical value, therefore, the urine should contain a strength of at least 1:30,000. Twice this strength is much more efficacious, as it would then be completely inhibitory to a majority of the organisms, and the best effect will be procured with a germicidal strength, or a solution of about 1:6,000.

TESTS FOR FORMALDEHYD AND METHOD OF QUANTITATIVE ESTIMATION

The marked instability of the two drugs, particularly with reference to acids and alkalies, should be given due consideration in applying tests for their detection, and the difficulty in a study of this kind, when an estimation of formaldehyd alone is desired, is greatly increased by the associated presence of the closely allied and unstable product, hexamethylenamin. It is not possible to use strong acids because the result is vitiated by a conversion of this substance. In addition the ease with which formaldehyd will combine with some inorganic and organic substances is to be remembered, and in the urine there are no doubt changes taking place that we know nothing about. Formaldehyd forms a soluble salt with uric acid, which suggested the use of hexamethylenamin in cases of urinary calculi, and, as the urine contains many similar substances, it is possible that in some cases very little formaldehyd is present because of the formation of certain by-products which may possibly give our color tests, and which may or may not be antiseptic.

Of the qualitative tests (Hehner's,[7] Shiff's,[8] Neuberg's,[9] Jorrison's,[10] Lebbin's,[11] the Amidol,[12] and Rimini's,[13] only the last three were found to be applicable to urine examinations, in that they were not interfered with by the associated presence of hexamethylenamin. Hehner's test was found of considerable negative value in showing the absence of both hexamethylenamin and formaldehyd. All of the tests are of value only qualitatively, and give no indication of the quantity of formaldehyd present, the main object in view.

An experimental study of some of the best considered quantitative methods of estimating formaldehyd was most discouraging, for reasons such as the instability and volatility of formaldehyd, the very small amount present and the associated presence of hexamethylenamin. No known method was found applicable for quantitative determination in the urine.

Quantitative Method of Estimation: Rimini[13] in 1898 published a phenylhydrazin-nitroprussid test as particularly applicable to foodstuffs, and it has since been found to be very reliable, provided certain precautions are observed. Anderson[14] reported it as one of the most reliable for formaldehyd, and in 1912 Burnam slightly modified the percentage dilution of the test drugs and applied it to urine examinations.

In the early experimental work with this test it was seen that there existed a definite relationship between the dilution of formaldehyd and that of one of the reagents, phenylhydrazin hydrochlorid; the more formaldehyd present, the less phenylhydrazin needed to obtain the reaction, and vice versa. This relationship gives a fairly uniform limit of reaction for the several formaldehyd dilutions and is the basis of the quantitative estimations to follow. The estimation is made by finding the weakest dilution of the test drugs that will give the characteristic blue-green-yellow reaction, and it was found convenient to represent the result in the form of a fraction, the numerator representing the dilution of phenylhydrazin, and the denominator that of the nitroprussid. Thus a 100/20 test indicates that this is the limit of reaction for that particular specimen, and by comparing this with the results on known dilutions of formaldehyd it will be seen to correspond to the limit of reaction of a known 1:40,000 solution. Therefore the specimen with this test has formaldehyd in dilution of about 1:40,000. Following this out for the other tests we obtain: 10/20 reaction equals a 1:60,000; 20/20, a 1:50,000; 100/20, a 1:40,000; 600/20, a 1:30,000; 800/20, a 1:20,000; 1,000/20, a 1:10,000, and 1,000/100, about a 1:7,000 dilution of formaldehyd.

THE ANTISEPTIC VALUE TO THE URINARY SYSTEM OF HEXAMETHYLENAMIN BY MOUTH

The patients, with five exceptions, were not normal cases. Thirty-two were old men with enlarged prostates, of which six were malignant. Fifteen patients had surgical disease of the kidney, six, disease of the bladder, twenty-four were gynecologic cases, three, medical, seventeen were in the department of general surgery and fourteen had some minor genito-urinary disease.

Significance of Disease of the Kidney: The kidneys of thirty-three of the 116 patients were definitely diseased, as indicated by the phenolsulphonephthalein test of Rowntree and Geraghty.[15] A number of these gave extremely poor phenolsulphonephthalein tests, three showing only a trace in one hour with a markedly delayed appearance time, in one not appearing for fifty-five minutes, in another for sixty-two. The findings in the forty-four cases in which phenolsulphonephthalein tests were made do not indicate that disease of the kidney exerts any influence whatsoever on the formaldehyd content in the urine.

Antiseptic Value of Formaldehyd at the Level of the Kidney: It has been generally believed that hexamethylenamin is converted into formaldehyd at the level of the kidneys. To be of value formaldehyd must be in the urine in the kidney in amounts of 1:30,000, or greater. To determine in what amounts formaldehyd is present the ureters of patients on hexamethylenamin were catheterized and the specimens from each kidney were examined immediately, and these findings compared to those on the urine voided just before the cystoscopy. Three of the bladder urines failed to show formaldehyd, whereas of the twenty-three catheterized urines, only five showed formaldehyd, and these five had only a 1 to 60,000 formaldehyd content. The eighteen negative urines all gave a positive Hehner's test, showing that hexamethylenamin was being excreted. That more formaldehyd is not formed is explained by the lack of time necessary for formaldehyd conversion in an acid medium. The hexamethylenamin as it is excreted from an alkaline blood is not allowed to remain at the level of the kidney long enough to give good conversion, and even with a high acidity and a high concentration the amount of formaldehyd at this level is seldom great enough to furnish antisepsis.

Antiseptic Value of Formaldehyd in the Bladder: Only four of the 116 cases failed to show formaldehyd. In each of these cases only one specimen was examined. The remaining 112 cases were positive for formaldehyd at some one examination. They may be conveniently grouped according to the highest test given at any time, and the examinations, which give a more just indication of values, may also be grouped according to the test reactions.

Only eight cases, or about 7 per cent., revealed formaldehyd in germicidal strength, and five of these patients had been fed on acid sodium phosphate, so that in only about 2 per cent. of the usual cases did the urine give the 1:7,000 test at any one time; 25 per cent. had formaldehyd in amounts to give complete bacterial inhibition, and 55 per cent. of the cases gave at some one examination a 1:30,000 test or better; 44 per cent. of the cases, although formaldehyd was present, at no time had this formaldehyd in sufficient amount to furnish antiseptic benefit.

Of the 318 examinations 36 per cent. were definitely antiseptic, and of these only 17 per cent. showed formaldehyd in strength to give complete bacteriostasis, and only 5 per cent. were germicidal; 64 per cent. had less than 1:30,000, and possessed no antiseptic value. (These results, owing to the fact that it was found impossible to examine all of the specimens immediately after being obtained, are no doubt high, but there is doubtless a slight error due to the instability of the test drugs, which would tend to correct the error due to an increase of formaldehyd on standing.)

FACTORS INFLUENCING FORMALDEHYD CONTENT

Several factors influence the amount of formaldehyd present in the urine of patients receiving hexamethylenamin by mouth. They are of two kinds, those that influence hexamethylenamin excretion, and those that influence hexamethylenamin conversion. All factors are more or less interdependent.

Influence of Urinary Acidity: In order definitely to determine the significance of the acidity of the urine to the amount of formaldehyd present in it, 10 c.c. of each specimen were titrated against tenth-normal sodium hydroxid, using phenolphthalein as indicator. The acidity varied from 0.1 to 7.9 c.c., the average of the 231 examinations being 3.1 c.c. Twenty-nine of the urines had an acidity of less than 1 c.c., and of these, thirteen were negative for formaldehyd and twelve others barely gave a test. There were two negative urines with an acidity between 1 and 2 c.c., whereas of the urines with an acidity above 2 c.c. all showed formaldehyd, and, with the exception of six cases, all showed formaldehyd in 1:40,000 dilution or better. There were 109 urines that gave 1:30,000 or better, and of these, 100 had an acidity of 2 c.c. or better, only nine an acidity between 1 and 2 c.c., and none with an acidity below 1 c.c. On the other hand, there were ninety-five urines that gave a test below 1:30,000 formaldehyd, and of these ninety-five, fifty-seven, or almost two-thirds, had an acidity below 2 c.c. This would indicate that a formaldehyd content of antiseptic value cannot be expected with a urinary acidity below 2 c.c. of tenth-normal sodium hydroxid.

The importance of urinary acidity to formaldehyd content in the urine is further demonstrated by the following observations:

1. The urine of a patient on hexamethylenamin, if acid, will after standing give a higher test for formaldehyd than when fresh. For example, 400 c.c. of urine voided at 11:30 was negative for formaldehyd, but at 3 p. m. the same urine gave a 1:30,000 test. On the other hand, a faintly-acid urine after standing five hours showed no increase in formaldehyd content, but when *this urine* was made acid by adding acid sodium phosphate, a 1:20,000 test was given in two hours.

This time element is an important factor to be considered in making tests. Every urine should be examined immediately after being voided in order to judge fairly its antiseptic properties while in the bladder. And this factor, together with that of urinary acidity, will explain the fact that a patient on forced water will show a low formaldehyd concentration as compared to a patient on the same dose but without polyuria. In the former case there is neither sufficient time nor acidity for the conversion of the hexamethylenamin in the bladder. When the acidity is high, however, a half hour seems time enough for good formaldehyd conversion, provided there is good concentration. In order to obtain the best results in cases of cystitis from hexamethylenamin therapy, therefore, the fluids should be partially restricted and the bladder emptied as infrequently as possible.

2. If hexamethylenamin is added to an acid urine it will be quickly converted into formaldehyd. On the other hand, hexamethylenamin added to a neutral or faintly acid urine shows none of this conversion.

3. The addition of acid sodium phosphate to the urine of a patient on hexamethylenamin negative for formaldehyd will convert the hexamethylenamin present. The addition of almost any acid will convert the hexamethylenamin.

4. Increasing or decreasing the acidity of the urine of a patient through his diet causes a corresponding change in the formaldehyd content of the urine.

Feeding milk of lime causes a diminution in urinary acidity, and in those cases in which it was used a complete disappearance of formaldehyd from the urine occurred.

Feeding acid sodium phosphate, boric acid, benzoic acid or salicylic acid will increase urinary acidity in cases in which it is low, and in these cases very definitely increases the amount of formaldehyd in the urine. The effect of any one of these acid-producing drugs will wear off after a time owing to body tolerance. When this occurs for any one it is possible to again raise acidity by substituting one of the other drugs in its place, and by thus alternating the use of the drugs acidity may be maintained for some time, in some cases, but not satisfactorily in all.

It is not well to give these drugs with the hexamethylenamin, since, as already shown, they tend to convert this, and might do so to such an extent in the stomach as to produce gastric irritation, as well as a loss for subsequent conversion in the urine.

Influence of Gastric Acidity: Hexamethylenamin is converted in the acid contents of the stomach. The amount of this conversion depends on the degree of gastric acidity, the amount of the drug exposed to its action, and the duration of this exposure. In one case in which 30 c.c. of contents were removed half an hour after giving hexamethylenamin, free formaldehyd was present in the proportion of 1:20,000, and after standing three hours the same contents showed a formaldehyd strength of 1:7,000.

In order to determine the significance of this formaldehyd thus formed in the stomach, formaldehyd solutions (6 ounces of a 1:3,000 or a 1:5,000 every three hours) were given by mouth to patients not on hexamethylenamin, and the urines carefully examined for both formaldehyd and for hexamethylenamin. These urines were all uniformly negative, even with the most delicate tests, showing that the formaldehyd was not being excreted either as formaldehyd or as hexamethylenamin. The blood of these patients was also examined with Hehner's, the Amidol and Rimini's tests, in each case with complete negative findings, indicating that formaldehyd was not present in the circulation nor had it been converted into hexamethylenamin in the alkaline medium either of the intestines or of the blood.

Chemists have been able to synthesize the simpler sugars from formaldehyd. Emil Fischer[16] and his pupils have formed most of the hexoses, and more recently Grube[17] showed through perfusion experiments on tortoise livers that formaldehyd acted as a glycogen former. This is the possible fate of these small amounts of formaldehyd when given by mouth.

These observations indicate that gastric acidity is a factor of influence in hexamethylenamin therapy, since the formaldehyd in the stomach is not excreted in the urine as formaldehyd or as hexamethylenamin. In cases of hyperacidity or poor gastric motility there is sufficient conversion in the stomach to considerably lower the formaldehyd content in the urine.

Feeding Salol-Coated Pills: In order to avoid the effects of gastric acidity hexamethylenamin may be given in salol-coated pills. Given in this way it will be largely excreted in the urine. The results of its use, however, did not show any great advantage through an increase in formaldehyd content over the usual manner of administration, and it takes from one to two hours longer for the drug to be detected in the urine. When given in this way in cases of hyperacidity there was a slight increase in formaldehyd content, but the difference was not great enough to recommend the method for routine use. Nevertheless, in cases of gastric irritability this mode of administration is applicable.

Influence of the Size of the Dose: In a few cases the routine of 15 grains three times a day was varied for purposes of comparison. The amount of hexamethylenamin excreted, the other factors being good, appears to be proportional to the amount ingested, but a large dose is not effective unless accompanied with a urinary acidity greater than 2 c.c. of tenth-normal sodium hydroxid. The value of smaller doses than 15 grains is very questionable. The drug can be given for months in fairly large doses with no untoward effects.

Influence of Curve of Excretion: Formaldehyd will begin to appear in an acid urine in sufficient quantities to be detected after the ingestion of an average dose (15 grains) in from twenty to thirty minutes, and will have disappeared in from eight to sixteen hours. The height of excretion is reached in from two to four hours and is maintained for four hours or longer. An eight-hour interval of administration will give good results in routine use, although a higher concentration is obtained with a more frequent medication.

SUMMARY OF THE FACTORS INFLUENCING THE FORMALDEHYD CONTENT IN THE URINE

These factors may be divided into two groups:

I. Those relating to hexamethylenamin excretion:

1. The larger the dose the higher will be the percentage concentration of the drug on excretion. Large doses may be given with no bad effects in the majority of cases, and small doses are useless in most cases.

2. The interval of administration should not be longer than eight hours, and shorter intervals will give a more continued maximum effect.

3. The character of the changes that occur in an acid stomach content forms an appreciable factor in certain cases of hyperacidity or of stasis. The amount of hexamethylenamin broken up in the stomach is that much loss for subsequent conversion in the urine.

II. Those relating to the conversion of hexamethylenamin:

1. The degree of urinary acidity is the most important factor, and should be greater than 2 c.c. of tenth-normal sodium hydroxid. It may be increased or maintained in some cases by feeding certain acid-producing drugs, of which acid sodium phosphate is the best. For practical purposes it is necessary only to know the acidity

of the urine in order to know the antiseptic value of formaldehyd in that case, provided the patient is getting large doses at regular intervals and has no gastric irritability or polyuria.

2. The duration of exposure to the influence of this acidity is of importance, so much so that on account of it the drug in medium-sized doses is of no use in kidney infections. It becomes of particular importance in cases of cystitis or of polyuria in which the patients void so frequently that time is not allowed for conversion of the hexamethylenamin in the bladder in amounts to be of antiseptic value. In estimating the antiseptic value of a urine it should always be fresh and not allowed to stand before testing.

3. The dilution of the drug on excretion largely influences the amount of it that is subsequently converted, as the higher its concentration the more readily will it be broken down. A polyuria, through the effect of dilution, will largely offset the advantage of large doses.

A COMPARATIVE STUDY OF THE ANTISEPTIC VALUES OF SOME OF THE ALLIED HEXAMETHYLENAMIN COMPOUND

Hexamethylenamin is dispensed under many proprietary names, such as urotropin, formin, aminoform, cystogen, etc. Certain of these are less irritant, but none of them liberate more formaldehyd than the pure drug, and in most cases not so much. In addition to these there are a number of other proprietary preparations for which an action superior to hexamethylenamin is claimed through the added benefit of the salt to which it is combined, such as helmitol,[18] hexal,[19] saliformin,[20] Myrmalyd,[21] Borovertin, Hetralin, etc. Of these only the first four were available for study, and these did not give as good a formaldehyd content as does hexamethylenamin.

CONCLUSIONS

1. The conversion of hexamethylenamin into formaldehyd is a simple chemical process which will readily occur in an acid medium but will not occur in an alkaline medium.

2. The amount of excretion of hexamethylenamin in the urine is influenced by the size of the dose, by the frequency of administration and by the character of the changes that occur in the acid contents of the stomach.

3. The amount of the subsequent conversion of this hexamethylenamin in the urine is dependent on the degree of urinary acidity, on the duration of exposure to the influence of this acidity and on the percentage concentration of the drug in it; and in order to give formaldehyd conversion in antiseptic amounts the urinary acidity should be greater than 2 c.c. of tenth-normal sodium hydroxid for 10 c.c. of urine.

4. A low acidity may be temporarily increased by feeding certain acid-producing drugs, and this increase in acidity may often be maintained by giving these drugs alternately.

5. Disease of the kidney has no influence whatsoever on the formaldehyd content in the urine.

6. At the level of the kidneys hexamethylenamin in doses of 15 grains three times a day has no antiseptic value.

7. Formaldehyd is present in the bladder urine in some amount in practically every case receiving 15 grains of hexamethylenamin by mouth three times a day, but this dosage is too small a routine from which to expect a reasonable antiseptic benefit in every case.

8. The allied hexamethylenamin compounds do not give greater antiseptic values than pure hexamethylenamin.

I wish to express my gratitude to Dr. Hugh H. Young for the privilege of this study, and to thank him and the several residents of the Johns Hopkins Hospital, Drs. Sladen, Heuer, Gibbes and Vest, for the clinical material.

THE PSEUDODIPHTHERIA ORGANISM IN THE URINARY TRACT *

WILLIAM WARREN TOWNSEND, M.D.
Professor Genito-Urinary Surgery, University of Vermont, College of Medicine
RUTLAND, VT.

The first of the following cases reported was one in which the symptoms of cystitis were most severe and resembled tuberculous cystitis. The bacteriologic examination and animal inoculation showed no tubercle bacilli, but did show the pseudodiphtheria bacillus in pure culture. Text-books on genito-urinary subjects do no more than mention the pseudodiphtheria bacillus as "an organism occasionally found in the urinary tract" and attach no importance to it pathologically. In reviewing the literature I find a case reported by Rosenow, in which the pseudodiphtheria organism was proved to be the etiologic factor. This organism is frequently associated with the gonococcus in chronic gonorrheas. I offer these facts as a reason for presenting the following case histories, summary of literature and report on the bacteriologic examination of eighty specimens of apparently normal urine.

CASE 1.—In January, 1911, a man, aged 21, unmarried, a farm hand, consulted me for dysuria and frequency of urination and remarked that the condition had been one of progressive intensity, beginning in 1909. The onset symptom occurred on a hot June afternoon while he was at work in the hay-field. He had been perspiring profusely and had been drinking a large quantity of water to quench his thirst. During urination he was seized with a severe pain along the course of the urethra which lasted several minutes and which quieted down in the intervals between urinations only to recur at each micturition. As the symptoms were continuous, and as he had had sexual intercourse a month previously, he thought that perhaps he had a gonorrhea and consulted the local village physician who, without making any physical or urinary examination, quite agreed with him in his diagnosis and gave him medicine to take. He continued to use it for several weeks without benefit to symptoms and then consulted other physicians and took a variety of medicines prescribed by them; acting on the advice of friends, he also took medicines that had helped them when they were in a "similar condition."

It is interesting to note that during the period of treatment, from June, 1909, to the time of consulting me in January, 1911, he at no time had received a urethral irrigation, nor had he been given a hand injection to use.

Examination.—When the patient first consulted me he was well nourished and all of his organs, not associated with the subjective symptoms, were normal; the family history was negative and no tuberculous predisposition could be elicited.

The urinary examination of a twenty-four-hour specimen showed a foul-smelling, alkaline urine, with many ropy, mucous sloughs resembling diphtheritic membrane. The spe-

---

* Read in the Section on Genito-Urinary Diseases of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

cific gravity was 1.014; there were a trace of albumin and an excess of phosphates; otherwise the urine was chemically normal; microscopically some pus and blood were found, but no histologic kidney elements or casts.

The external genitalia were negative, likewise the prostate and vesicles. The urethra was of normal caliber, and other than for a marked spasmodic contraction of the compressor the catheter passed easily and showed a residium of 12 c.c. Urethroscopic examination of the anterior urethra was negative; the posterior urethra in the prostatic portion was much congested and bled freely when touched. The verumontanum was hypertrophied and granular in appearance. The cystoscopic picture was that of a contracted bladder holding only 70 c.c. A diffuse inflammation of the mucosa existed and a highly congested trigon, which also bled when touched. Surrounding the right ureteral opening there was a mass of bullous edema. The left ureteral opening was normal in appearance, and attached to the mucosa posterior to the right ureteral orifice and extending up on the posterior wall was a membrane 2.5 by 3.25 cm. having the appearance of a diphtheritic membrane. It could not be loosened with the tip of the ureteral catheter and a prolonged attempt to loosen it was prevented by the vesical spasm which expelled the distending medium. Any further attempt at catheterizing the ureters was obviated by the increasing intolerance of the bladder.

Diagnosis and Treatment.—As a result of the clinical findings at this cystoscopy, a tentative clinical diagnosis of right renal tuberculosis was made, and the urine from the bladder was sent to the laboratory for bacteriologic examination and animal inoculation. The patient was put on general urinary antiseptics, and local treatment to the bladder was instituted with a view to future cystoscopy and renal investigation.

Laboratory Findings.—A smear examination of the centrifugalized urine brought the report of an organism "identical in morphology with the Klebs-Loeffler bacillus." Cultivation was made and the organism was found to be present in pure culture. I thought that there might have been some contamination due to faulty technic while obtaining the specimen, or in the laboratory, and obtained another specimen and divided it equally, sending one-half to the Vermont State Laboratory and the other half to Dr. H. J. Perry of the Harvard Bacteriological Laboratory with instructions to "study the bacteriology of the specimen." The work was carried on in each laboratory absolutely independently and both reported in substance as follows:

The bacillus was isolated from the urine and was exceedingly variable in size and shape, but in a general way resembled members of the diphtheria group, though averaging thicker, less delicate in shape, with fewer polar bodies and with more breaking up of the bacilli into shorter organisms than is usual with the true diphtheria bacillus. In certain classes, forms resembling in a general way Wesbrook's Type A were seen. From the morphologic point of view it seemed that the bacillus was of the diphtheria group, but not the true diphtheria bacillus, although resembling it in certain ways. When stained with Loeffler's methylene blue it was impossible to bring out the polar bodies, as can usually be done in the pure diphtheria bacillus. On blood-serum the separate colonies resembled closely the diphtheria bacillus. Cultures were made in various sugar-broths, dextrose, saccharose, lactose, dextrin, etc., and the presence of increased acidity, especially in dextrose broth, could not be determined. The negative character of the reactions with the sugar showed that the bacillus might be the pseudodiphtheria bacillus. Guinea-pigs were inoculated with large doses of pure culture in broth and nothing followed the inoculation; the animals were not even made sick by the inoculation.

Cultures were taken from the patient's nasopharynx and from his blood with negative results.

As a result of the continued bladder irrigations and urinary antiseptics the bladder became more tolerant to instrumentation. The physical and bacteriologic properties of the urine, however, and the subjective symptoms, namely, dysuria and frequency, continued. A second cystoscopy and ureteral catheterization were done and the bladder was found to be less contracted and a general betterment of the pathologic appearance was noted. The kidneys were catheterized; the segregated urine was sent to the laboratory and a cultural bacteriologic examination showed that the "specimen from the right kidney contained organisms identical in morphology with the Klebs-Loeffler bacillus. Urine from the left kidney was sterile."

Further Treatment and Course.—Through the courtesy of Dr. Robert H. Herbst of Chicago I received sufficient vaccine to treat my patient and I continued its use most systematically without apparent benefit. This vaccine was prepared as the result of a study into the etiology of twenty-six cases of chancroid made by Dr. Herbst, who reported these cases at the September, 1911, meeting of the American Urological Society held in Chicago. Herbst[1] found that the pseudodiphtheria bacillus resembles very closely the Ducrey bacillus; he found it present in thirteen of the twenty-six cases studied and as a result of treatment by the vaccine prepared he asserts that he cured his patients. I also used an autogenous vaccine without apparent benefit. At no time during my observation of the case did I note any constitutional symptoms, namely, high temperature, etc.

The spasmodic constriction of the membranous urethra noted at the first examination manifested itself at every subsequent examination or treatment of the bladder; overdilatation and local treatment rectified this condition. At about this time the subjective symptoms and urine began to clear up.

The bladder had been irrigated with the various silver salts and boric acid and, as no mercurial solution had been used, it was tried in the form of mercuric cyanid in a 1:1,000 solution. Irrigations were made every day and an attempt at bladder distention was made at each treatment. The urine was sent for bacteriologic examination regularly and while the pseudodiphtheria bacillus was the predominating organism, the *Staphylococcus albus* was noted at each culture as a contamination. As it did not appear in the early urinary cultures, its presence during the stage of improvement was interesting. At the time of writing (Jan. 31, 1912), the staphylococcus is the only organism that can be cultivated, and the patient is cured of the subjective symptoms. The urine is much less puriform.

I consider the finding of the pseudodiphtheria bacillus from the right kidney at the time of the second cystoscopy due to contamination of the eye of the ureter catheter during its passage through the bladder and mass of bullous edema.

In order to appreciate the similarity of this case to that reported by Rosenow,[2] it will be necessary to abstract his article in some detail.

Case 2.—Rosenow's patient was a woman, unmarried, typesetter, aged 23. After removal of the tubes and ovaries, on account of intense nervousness, painful menstruation and vaginal discharge, she was six months later taken with a chill, followed by painful, frequent and bloody micturition, tenesmus, fever and prostration.

Examination and Course.—A cystoscopic examination by Dr. J. Clarence Webster showed a large irregularly ulcerated area, approximately 4 by 5 cm., on the posterior wall of the bladder behind the trigon; the base of some of the ulcers was irregular and grayish, with necrotic patches, while others were clean. Two days after cystoscopy the patient was suffering excruciating pain in the bladder and back, associated with a constant desire to urinate, extreme tenesmus and burning. The twenty-four-hour specimen of urine, 720 c.c., was turbid, but not bloody, and alkaline; specific gravity was 1.015. It contained a large amount of albumin, a few leukocytes and epithelial cells, but no casts. Stained specimens of sediment showed Gram-negative, moderately mobile bacilli

[2] Rosenow, E. C.: Immunologic Observations in Ulcerative Cystitis Caused by Pseudodiphtheria Bacillus, Jour. Infec. Dis., 1909, vi. 296.

> and a fair number of Gram-positive bacilli resembling the diphtheria group. These bacilli were always more numerous in a twenty-four-hour specimen or in a single specimen which had stood for a period. The temperature during an exacerbation of the bladder symptoms went up to 100 F.; otherwise it was normal.
>
> Cultures from scrapings from the margin of the ulcerated area as well as from the vagina yielded the diphtheria-like bacillus in predominating numbers; only a few colon bacilli and staphylococcus colonies developed. Occasional specimens of urine for eight months longer showed a gradual diminution in the number of leukocytes and albumin and a total disappearance of the Gram-positive bacilli. Improvement in the patient's general and local condition was also marked.
>
> *Diagnosis.*—Inoculation experiments in guinea-pigs showed that the bacillus was one of moderate virulence and that diphtheria antitoxin failed to protect against the organism, as has been the case with other virulent pseudodiphtheria bacilli. Inasmuch as the growth on various mediums resembled closely that of diphtheria bacilli, especially after they had been cultivated for a time, and for the reason that antitoxin failed to protect, it would seem justifiable to regard the bacillus as a so-called virulent pseudodiphtheria bacillus.
>
> *Conclusions.*—Rosenow summarizes his conclusions as follows:
>
> The diphtheritic ulceration of the bladder in this case was caused by the pseudodiphtheria bacillus for the following reasons:
>
> 1. The constant presence of the bacillus in the urine and its predominance in the smears from the scrapings.
> 2. The specific and peculiar behavior of the blood toward this bacillus, especially after the injection of dead bacteria, with apparent benefit for the patient.
> 3. The high agglutinating power of the serum on this bacillus and absence of such power on the colon bacillus.

The pseudodiphtheria organism is frequently found in the cultures made from the discharge of gonorrheics.

Through the courtesy of E. L. Keyes, Jr., I have had the opportunity of looking over the data obtained by his bacteriologist in the examination of eighty-six cases of urethritis. The pseudo-organism was found nineteen times, twice pure and in the other instances associated with the gonococcus and the staphylococcus. Dr. Keyes also reports to me another case "involving the anterior urethra almost exclusively. The only organism found was the pseudodiphtheria bacillus, and this was clumped in such masses about the small shreds in the urine that it seemed quite likely that this was the infecting organism."

A. P. Ohlmacher[3] reports that while engaged in the task of recovering and cultivating the gonococcus he encountered the pseudodiphtheria bacillus as an inhabitant of the pus from acute gonorrheal arthritis. The association of this bacillus and the gonococcus was noted on several occasions and from different individuals, and it was one of the features rendering more difficult the recovery of the gonococcus in pure culture. From these observations he concluded that their companionship was not an accident, but was fraught with importance, especially from the point of view of therapeutic bacterial immunization in gonorrhea.

In order to determine the frequency with which the organism inhabited the genito-urinary tract, I obtained the apparently normal urine of eighty prisoners in a penitentiary with which I have a visiting association. The external genitalia were thoroughly sterilized, and the urine was voided into a sterile container and then poured into a sterilized glass tube and centrifugalized. The sediment thus obtained was planted in Loeffler's blood-serum and incubated. Ten of the eighty specimens taken, or 12 per cent., showed a growth of pseudodiphtheria bacilli and in every intsance staphylococci. The ten prisoners from whom the positive urines were obtained were further examined with a view of locating the part of the urinary tract inhabited by the organism. Omitting the technic, it may suffice to say that cultures were made from the anterior and posterior urethra and from the posterior urethra following massage of the prostate. In all the instances the organism was cultured from the anterior urethra and once from the sediment of the urine catheterized from the left kidney.

In a personal communication, Dr. John T. Geraghty of Baltimore informed me that in the study of the bacteriology of prostatitis in connection with the preparation of an article[4] on that subject the pseudodiphtheria organism was not cultivated. This is in accord with my own findings, as it will be noted that I was unable to obtain it from the posterior urethra either before or after massage of the prostate. In the ten instances in which it was found, six acknowledged having had gonorrhea, and two gave a history of having had diphtheria.

Hermann Pfeiffer,[5] writing in 1903, states that he examined fifteen normal and twelve gonorrheal urethras and could, after the study of these few cases, detect a certain constancy of events; in the first series, namely, the fifteen normal urethras, he succeeded eleven times and, in the second series, six times in finding organisms "belonging to the diphtheria group," not only on the cover-glass, but also in great numbers in culture-tubes. The fact that these bacteria are so constantly found on the urethral mucous membrane, is, he adds, so far as his literary knowledge of the subject goes, new.

Sven Wall[6] reports having made pure cultures of the pseudodiphtheria bacillus from the kidneys of cows that had suffered from pyelonephritis.

Many cases are reported of true diphtheria of the renal pelvis[7] and of the bladder, and in going over the literature it is noted that while there is a marked similarity in the clinical findings of the reviewed reports, still in all of the cases there were distinct constitutional symptoms, and the bacteriologic examination was positive.

The clinical symptoms of cystitis in which the pseudodiphtheria bacillus seems to be the causative factor closely resemble the cases of necrosis of the bladder collected and studied by O'Neil.[8] In so far as I could learn, however, in none of the reports collected by him, or in his own cases, was the bacteriology studied. Trauma in each instance was ascribed as the primary cause, with infection as the contributing factor.

Aufrecht[9] in 1882 made experiments in which he sealed the meatus of a large, strong, male rabbit, and *in toto* obstructed urination four times for twenty-four hours. On section of the bladder at necropsy it was covered with purulent masses, thickened and infiltrated, and Aufrecht states that there was nothing to distinguish it from diphtheritic areas in the mucous membrane of the human throat. He is of the opinion that it adds weight to the view of Billroth, Tiezel, etc., that in animal organisms there may be microbes that under proper conditions—for example, nutritional disturbance of the bladder wall caused by trauma—may produce deleterious results both by their multiplication and by their change of form.

Realizing the number of instances in which the organism is found in the normal urethra and urine, it would not be beyond reason to consider at least the possibility that the pseudodiphtheria organism may play an important rôle in the cases reported by O'Neil, especially in those described as membranous cystitis, which are pathologically different from the cases of necrosis.

In order to appreciate the plausibility, at least, of the theory that the pseudodiphtheria bacillus is the cause of some forms of cystitis, it is necessary to determine the lesions produced by the bacillus in other parts of the body and to study the present status of this organism in the bacteriologic nomenclature.

In glancing over the vast literature on this subject, I am struck and confused with the various contradictory statements by bacteriologists of great repute. No organism has been the topic of so much discussion and dispute as the so-called pseudodiphtheria bacillus, and it seems as if the last word in the controversy between unicists and dualists has not yet been spoken.

Loeffler in April, 1887, cultured from a diphtheritic membrane two different bacilli, one of which was pathogenic for guinea-pigs, the other harmless. About the same time Von Hofmann-Wellenhof found the same bacillus and called it the pseudodiphtheria bacillus. Their better growth on agar and their shortness and thickness were sufficient grounds for him and Loeffler to separate this organism from the true diphtheria bacillus. Roux and Yersin, however, in 1890, demonstrated that the virulent bacillus of diphtheria may be artificially made avirulent and take on all the characteristics of the pseudodiphtheria bacillus. The pseudobacillus to them is only an attenuated form of the diphtheria bacillus, and investigators like Morel, Martin, C. Frankel, Behring, Ritter and Koplik, shared their opinion.

L. Martin distinguished three varieties of the diphtheria bacillus, a long, a short and a medium type. According to him and his followers, the short type is identical with the pseudobacillus of the German bacteriologists. This view is held by Chatin and Lesieur,[10] Roussel and Job,[11] Schanz,[12] and most emphatically defended in a recent original publication by Laurent[13] of Stockholm, who states that his observations have fully convinced him that the view originally advocated by Roux and Yersin is the only correct one. Zarniko observed that the diphtheria bacillus caused an active production of acid in broth, and the pseudo, faintly acid or alkaline, and Escherich made the statement that the acid producers were always virulent and the non-acid producers avirulent. Exceptions to this rule were numerous enough to invalidate this as an absolute test.

Bacteriologists gradually began to admit that cultural peculiarities, morphology, presence of Neisser granules, chemical activity or virulence for animals and the like all failed to draw a line between the true and the false diphtheria bacillus, and that the only hope for a sure method of differentiation lay in the application of specific serums to neutralize specific toxins. Spronck[14] of Utrecht, experimenting with the short bacilli of the French authors, found two strains without any virulence, but two other strains injected under the skin of guinea-pigs produced edema, loss of weight, lack of appetite and other constitutional symptoms. As antidiphtheritic serum did not prevent these symptoms, he concluded that there exists in the anginas a pseudodiphtheria bacillus, pathogenic for the guinea-pig, until now not known, or mistaken for the true diphtheria bacillus. "This bacillus corresponds absolutely with the small bacillus of Martin."

Alice Hamilton,[15] in this country, followed Spronck's method, found twenty-six different pseudodiphtheria bacilli and divided them into three types and grouped them as follows:

Group 1, non-pathogenic to guinea-pigs.

Group 2, pathogenic to man, "which should be further studied."

Group 3, pathogenic to guinea-pigs.

Two varieties, Hamilton[16] writes, are found frequently in suppurative processes, especially in the pus of postscarlatinal otitis media. In this disease, she says, they are found so frequently as to render it probable that they play an important part in its causation.

Howard reports a fatal case of ulcerative endocarditis in which a pure culture of the diphtheria-like organism existed which did not prove fatal to guinea-pigs.

Rudinger[17] reported a series of cases of gangrenous tonsillitis and pharyngitis in which the pseudodiphtheria bacillus was found in pure culture.

As Pennington[18] says:

> We meet recent evidence that morphologically and clinically the most satisfactory pseudo forms have a decided pathogenicity for guinea-pigs, and from clinical evidence for human beings; hence the harmlessness of these germs cannot be accepted unconditionally, any more than a certain virulence can be attached invariably to a diphtheria bacillus which agrees with some arbitrary requirement laid down by bacteriologists.

From the genito-urinary clinician's point of view, it matters little whether the organism found in the case presented here must be labeled a form of the Klebs-Loeffler bacillus, or a variety of another organism *sui generis*, the all-important fact for us as genito-urinary clinicians is that this organism is or may become a destroyer of health in the human economy, and that in the genito-urinary tract its significance is of greater moment than has hitherto been acknowledged.

Schiötz[19] of Copenhagen and Musgrave[20] of Manila have called attention to the fact that the Klebs-Loeffler bacillus can be driven out by the staphylococcus, and the Danish physician inoculated diphtheria patients with pure cultures of staphylococci with curative results.

It is suggestive, to say the least, that in my case also during the acuteness of the symptoms the pseudobacillus was found alone, and when the staphylococcus made its appearance as a contamination of the frequent treatments the symptoms subsided, and now (Feb. 27, 1912) the urine is free from pseudodiphtheria bacilli, and staphylococci alone are present.

In the case reported to me by Keyes also, in which the pseudobacillus was "clumped about the shreds," it was alone. In the other cases of chronic urethritis in which the bacteriology was studied it was associated with the gonococcus and the staphylococcus.

CONCLUSION

As a result of my study and observation, it is my firm conviction that under the proper conditions a pseudodiphtheria bacillus in the genito-urinary tract can become a pathogenic organism; that it is more common as an etiologic factor than is appreciated by the textbooks, as evidenced in the numerous cases of chronic urethritis in which it is found, in the cases reported by Rosenow and in the one studied by me.

My findings endorse fully Brown's[21] statement, "that it is not at all uncommon as a sequence of gonorrhea to find a bacteriorrhea in which the urine shows large numbers of organisms of different forms, which undoubtedly tend to keep up the inflammation."

Without asserting that the pseudobacillus is always a pathogenic organism, unless overridden and controlled by the staphylococcus, I do believe that in our branch of medicine also the subject of symbiosis is one for further study by the bacteriologists and of vast clinical interest to us in the treatment of rebellious conditions of the genito-urinary tract.

My appreciation and thanks are due to Drs. E. L. Keyes, Jr., Henry J. Perry of the Harvard Medical School, Bingham H. Stone, E. H. Buttles and Percy Carpenter of the Laboratory of Research, Medical College of the University of Vermont, H. A. Bosma of New York and others for the various courtesies extended during the preparation of this paper.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. TOWNSEND, HINMAN AND HEIDINGSFELD

DR. G. G. SMITH, Boston: There is only one point in which I should not agree with Dr. Hinman entirely, and that is that hexamethylenamin in doses of 15 grains, three times a day, could have no effect on the pelvis of the kidney. It may well be that catheterized specimens from the kidney show a proportion of liquor formaldehyd in the urine which is below bactericidal power, but it seems to me that clinical experience has shown that that dosage is of value, and I think this is one of the instances in which we must take the experimental findings with a grain of salt. The clinical findings indicate that hexamethylenamin has a certain amount of value in those conditions. I should like to ask Dr. Hinman what he considers a good average dose of hexamethylenamin?

We have tried various drugs with it and have met with some difficulty in the employment of nearly all of them. Boric acid, I am sure, has caused toxic symptoms in some cases, and the acid sodium phosphate is likely to cause diarrhea. It seems to me that we have still to find a drug which will increase the acidity of the urine.

DR. M. KROTOSZYNER, San Francisco: Dr. Hinman deserves much credit for his painstaking investigations on the efficacy of hexamethylenamin. Not only the general practitioner, but also the urologist, expects almost wonders from this drug, which, therefore, is given promiscuously and dogmatically over a long period in almost all affections of the genito-urinary tract, in which no proper diagnosis has been made. Of particular importance in this connection I consider the fact which was brought out by Dr. Hinman's paper, that large doses of hexamethylenamin, for instance, 15 grains three times a day, are in the majority of instances ineffective on the underlying condition. I am in hearty accord with Dr. Heidingsfeld's demand for a continuous and personal supervision of the Wassermann reaction. Unless we can follow out our treatment by the personal study of the test at close range, I should not lay much stress on it. I also fully believe that our old standby, mercury, has proved to be just as efficacious and indispensable since the advent of salvarsan as it was in the presalvarsan era.

DR. H. A. COHEN, Minneapolis: I do not believe that time will banish the insoluble salts of mercury. Finger, whose work on syphilis is done with as great care as in any clinic in the world, holds that, after the primary stage and very early secondaries, salvarsan should be used with great caution. Already 147 fatalities have occurred. In the sixty-one years of the use of intramuscular injections of mercury, but sixty fatalities have been reported. He does claim that the *sterilisans magna* can be realized by a large early dose of salvarsan in a Wassermann negative case. The many neurorecurrences which take place are conditions which are found most frequently in the late secondary and the tertiary cases, and those neurorecurrences are due to the toxic salvarsan and toxic arsenic condition. We therefore have a double condition to watch, that is, the dosage of the drug itself and the possibility of the body being thoroughly saturated with the spirochetes and never being attacked.

DR. A. L. WOLBARST, New York: Dr. Cohen spoke of 147 deaths from salvarsan reported by Finger. In considering the toxicity of salvarsan, the number of deaths that have been reported must be judged in comparison with the total number of injections that have been administered. If two hundred or five hundred or one thousand injections had been given, and of this number of patients 147 had died, it would be fair to say that the remedy is *per se* a dangerous one; but many hundreds of thousands of injections have been given, many of them by incompetent men and in direct violation of every surgical canon, and, if in this great aggregate there have been but 147 deaths (conceding the number for the moment), it stands to reason that the deaths were not due to the salvarsan itself, but to some extraneous or concomitant conditions, acting in those particular cases, that were not observed in the patient. The patient might have had an idiosyncrasy to arsenic. Such deaths might have been avoided if a preliminary injection of a small dose had been given, as suggested. In the majority of cases in which death followed there have been serious errors in technic. Strict asepsis and functionating kidneys are imperative. When I read of a death following salvarsan and scratch beneath the surface, I am sure to find a serious error, either in the manner of administration, or in the fact that the patient was not suited to the treatment. In most of the fatal cases, if not in all of them, the patient's kidneys do not eliminate the arsenic content of the salvarsan, with the result that toxic results follow. In some of these patients the kidneys are so poor that they cannot eliminate a strong dose of mercury or any other toxic drug. Surely, a fatal result in such cases should be ascribed not to the drug, but to its faulty administration.

We are still in the experimental stage in the use of salvarsan, and while we have a great deal to learn regarding its effectiveness, certain things have been proved which make it by far the most important single factor in the treatment of syphilis. Whether salvarsan should be used exclusively in the beginning, or in the middle, or toward the end of syphilis must still be determined, but we do know that salvarsan has given wonderful results in every stage and form of human syphilis. True, it has occasionally failed to come up to expectations, but so has mercury and so has every other remedy for every other human ailment. We all know that there are some cases that resist mercury, and the harder the mercury is pushed the stronger the antagonism to the drug becomes. The same may be true of salvarsan. I believe, however, that with salvarsan at our command we can attack syphilis with greater certainty of good results than ever before. I think it will in time supersede mercury as our first reliance in syphilis. We are not yet quite ready for that, because we do not know enough about it, but, if I can judge from my own experience, covering about three thousand injections, I am satisfied that mercury will eventually become the second line of attack — a reinforcement of salvarsan, as it were. In the meantime, I think it proper that both drugs be employed in every case of syphilis. Finally, I would add that these remarks apply equally well to neosalvarsan as to salvarsan.

---

[21] Brown, T. R.: Johns Hopkins Hosp. Rep., 1902, x, 11; In Osler's Modern Medicine, 1909, vi, 236 and 218.

Dr. E. G. Ballenger, Atlanta, Ga.: My experience with salvarsan has been that the greatest danger comes not from giving too much, but from giving too little. We should repeat medium-sized doses and keep them up for a considerable period of time, administering mercury either simultaneously or later. I think the danger of neurorecurrences comes when we give but one or two doses in the early secondary period. The neurorecurrences that I have seen have almost invariably been in that stage of the disease, and improvement has always followed the repetition of salvarsan and neosalvarsan. I think that fact points away from the toxic effect of the remedy, and I have not hesitated to repeat the dose of salvarsan. At first I was in doubt, but the improvement was so prompt when I repeated the injections that I have since repeated them as soon as I have seen evidence of auditory or ocular neurorecurrences.

Instead of pitting salvarsan against mercury we should pit both against syphilis. Of course, we have secured good results with mercury in the past, and yet we have but to think of the many cases of paresis, tabes, aneurysm, cardiac lesions and various other luetic affections to see wherein mercury has not done all that it should have done. It has had about four hundred years' trial. Certainly the advances we have made enable us to make better headway and to give the patient much more satisfactory treatment than formerly.

As has been emphasized by nearly all discussing the treatment, we cannot have a routine method. We must treat the patients individually and persistently until the clinical symptoms disappear and the blood and spinal fluid show negative serologic tests.

Dr. J. T. Geraghty, Baltimore: In the first fifteen cases in our clinic in which salvarsan was employed, two neurorecurrences were found within a few months. These patients received only one injection and no other treatment. Subsequently mercury and repeated injections of salvarsan became the routine, and during the last two years we have not had a single neurorecurrence in the cases treated in this way.

Dr. Louis E. Schmidt, Chicago: I am not a believer in giving one injection of salvarsan and then a Wassermann, because no matter whether or not the test is carried out by an expert a negative reaction is not an absolute indication of cure. I believe that the intermittent form of mercurial treatment should be kept up for an indefinite period of time. If you give salvarsan and find the reaction negative, and then repeat it in the course of thirty or sixty days, and again find that you have a negative Wassermann, I hardly see why you should expect later manifestations. I think that we should give repeated doses, and alternate with mercury, and then rest from thirty to sixty days and watch the reaction. During the first year we should give an interrupted course of mercurial treatment as we did formerly, and naturally, in the following years keep up the Wassermann reactions and at the same time continue mercurial treatment, but not with the same regularity as during the first year's treatment.

Dr. Victor Vecki, San Francisco: I know that we have to take the middle way. We are between the one extreme that Professor Finger of Vienna represents, and the other extreme represented by Wechselmann. The latter lays all the deaths from salvarsan at the door of mercury. He maintains that mercury rendered the kidneys insufficient, causing vascular hyposthenuria, and that consequently the kidneys were not able to eliminate the salvarsan and thus caused all these deaths. It is not even the fault of the technic; you can do anything you wish with salvarsan, only do not use any mercury.

While I have reported a fatal case of syphilitic myelitis after intramuscular injection of salvarsan, I fortunately have no experience with death caused by salvarsan directly. I think that this is due to the circumstance that I did not wait for Wechselmann to tell me to watch carefully the functionability of the kidneys before using salvarsan. The therapy of syphilis belongs to the urologist. The dermatologist may be a fine man in diagnosing the cutaneous symptoms of lues, but when it comes to treating syphilis, the dermatologist cannot have the proper idea of the functions of the kidney. Our present methods of testing the kidney functions are rather crude, and I am sure that in the future the blood itself will have to be examined more carefully. What I want to emphasize is, in answer to any one who maintains that mercury did not do the work in the last four hundred years, that it did whenever it was properly employed. I have never seen the fourth stage of syphilis in a case that was treated properly with mercury.

Dr. M. L. Heidingsfeld, Cincinnati: I was favorably impressed with the remarks of the first speaker in reference to the reports in regard to Wassermanns. A Wassermann to my mind and in my experience is thoroughly trustworthy if it is carried out properly. It is a test of great detail and accuracy and requires most painstaking methods, and I am sorry that a great many laboratories are not particular to give reliable reports. I know that their methods are not accurate.

It is perfectly apparent to every one that mercurial treatment is an aid in these cases, but I cannot see the rationale of giving mercury if it is not necessary. If we effect a complete cure in some of these early cases of syphilis, in the initial stage, what is the object of subjecting a man to two or three years' of mercurial injections and inunctions when that has proved itself to be unnecessary? I think that the Wassermann reaction is the mentor and the oracle of syphilis; it is the arbiter and should go hand in hand with the consulting physician.

We have had four hundred years of mercury, and we have had four hundred years of unsatisfactory results. We have had many years of deep muscular injections of insoluble salts and the Wassermann has shown that many of these cases have been treated successfully. I believe in mercury injections; I believe in cacodylate of sodium, but they must be used in connection with the Wassermann, and the Wassermann gives us the best information in that direction.

We must not be guided by any one man, and particularly not by a man like Finger, who has been pessimistic in regard to salvarsan from the beginning. The unfavorable results, according to Ehrlich, are not due to salvarsan, but to errors in technic, and since syphilographers have been using distilled water they have eliminated them almost entirely. We have evidence that some of the cases of death were due to errors of technic, the use of water that was not distilled. It is notorious that the men with small experience are the men with most unfavorable results; the men with large experience have had few unfavorable results.

CORRECTION OF IMPEDIMENTS OF SPEECH IN OUR PUBLIC SCHOOLS *

HARRY F. McBEATH, M.D.
MILWAUKEE, WIS.

There is no common ailment which I believe has received less consideration at the hands of the medical profession than that of stammering. The subject was given but small consideration up to the beginning of the nineteenth century, at which time it was seriously studied by Arnott, Columbat, and Schulthers. A little later came the period of surgical enthusiasm, originated by the work of Diffenbach. Through the efforts of Kussmaul, Gutsmann, and Wyllie the knowledge of the subject was placed on a sound scientific basis. Perhaps the most exhaustive study ever given the subject was by our own noted scientist, Prof. Alexander Melville Bell. To-day the question is kept alive by a limited number of men, foremost among whom may be mentioned Dr. G. Hudson-Makuen of Philadelphia and Dr. E. W. Scripture of Columbia University.

---

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

The medical profession as a whole, however, has never given the subject the serious study it deserves. Patients are frequently advised by men otherwise competent in their line of work to pay no attention to their stammering, as they will in time outgrow it. As a result of our neglect the field has been almost entirely usurped by the charlatan. This not only deprives the stammerer of the help to which he is entitled, but discourages properly directed work along this line. We have never before given weight to the work of mountebanks, but in this connection it would appear as though their results were the basis for the poor prognosis generally given out by medical men.

Analyzing stammering as we do other maladies, do we find about it anything that would place it in the category of hopeless cases or justify the indifference usually shown these patients? There has been much discussion regarding the difference between stuttering and stammering, and while it may be of clinical interest, essentially they are but a different expression of the same underlying state and may, therefore, be covered under the one term stammering.

The most common causes of stammering may be given as conscious or unconscious imitation, shock, and the exaggerated effort to speak, such as occurs during and after debilitating diseases. These causes are active up to the time that stammering is established, when they become inoperative. After this the condition is dependent on emotional disturbances, in the presence of which the patient is unable to speak correctly because he is afraid of stammering. Therefore, stammering is a psychoneurosis, with fear its basic element. With the elimination of fear, there is a speedy return to normal. The stammering patient is entirely ignorant of how to direct his efforts to produce normal speech. He knows what he wants to do, but does not know how to do it. Just as soon as he acquires the knowledge of how to proceed to speak he is relieved of his fear of stammering. In the stammerer the psychologic processes of speech are normal up to the point at which the central innervations leave the mind. Here the neurosis assumes control and gives rise to a clonic or tonic spasm of the muscles controlling speech.

The treatment consists in bringing to a state of perfection, in the order named, the acts of respiration, phonation, and articulation. Perfect respiration not only insures a sufficient volume of air for voice production but also relieves the spasm, and puts under volitional control the muscles concerned in speech. In the words of Dr. Makuen, "good breath control is absolutely essential to good voice production." With reference to phonation Professor Bell tells us that "voice is the material of speech, and this fact in all its meaning the stammerer has to learn. He must have voice, whatever else he lacks, and must therefore acquire command of a full, strong, unbroken stream of sound."

Articulation is of minor importance and need not occupy the mind of the patient until after his speech is stable. As tersely expressed by Professor Bell, "the mouth tube is constantly varying in shape, but it is always a transmitter only, and never an originator of sound. All effort thrown into the mouth, jaws, lips, or tongue is futile. These should be passive as nearly as possible." The patient having mastered the exercises which give him control of his speech apparatus there remains but the psychologic condition of habit with which to deal, and continued practice along correct lines in time displaces the abnormal in the channels of the mind.

Prof. Frank A. Reed, who elaborated on and made use of Professor Bell's principles in thousands of cases, puts his views in the following words: "The whole philosophy of the scientific overcoming of the stammering habit may be summed up in the simple statement that it consists of the acquirement of sufficient self-control and skill to assure the complete control of the breath at the diaphragm and its absolutely free, unhampered outflow from that point." Dr. Scripture insists that before treatment is instituted a diagnosis should be made by a competent physician. At this time the patient should be examined and treated for physical defects which would tend to make his recovery difficult. Nasal stenosis should not be overlooked. Dr. Makuen writes: "I have been struck with the frequency of intranasal obstruction and pressure in these cases due to irregularities of the septum, and almost all stammerers have a marked irritability of the pharynx, which I think is to some extent responsible for their difficulty of speech."

Having made sure that these patients will be benefited by the application of the principles herein advised, there is no reason why they may not be entrusted to a specially instructed teacher. It does not require a mind with the technical training of a physician to comprehend the principles on which the work is to be carried out. The most approved methods for gaining control of the physiologic processes which go to make up speech, having been given in detail by those competent, can surely be followed by a properly trained teacher. It is special work and the classes must be small; one year, however, will usually accomplish the desired results, and where can we find another special department which in any length of time graduates a child with a return to normal to crown its efforts?

Statistics covering over three thousand cases show a complete loss of the impediment in 80 per cent. This has been raised to 98 per cent. in three hundred cases treated in the public schools of Milwaukee, where the pupils are held in special classes at the discrimination of the teacher. Quicker results would be obtained if stammerers received all their instruction in special classes. Much is lost by allowing them to take their regular studies under teachers who do not understand their condition. These special departments once established will be in a position to take advantage of most cases at their inception, thereby gaining a maximum result with a minimum effort. There are in the schools of the United States 13,143 deaf pupils. Of these 75.4 per cent. are being taught speech. Does it seem reasonable that so little should be done for the multitude of stammerers, who with comparatively small effort could be made the equals of their fellowmen?

The attitude assumed by some, that the stammerer gets along as well as any one, and that it matters little whether or not he is relieved, may be pardoned in the laity, but can hardly be tolerated in the medical profession. Those who are in a position to know can verify that there are but few afflictions in which the mental anguish is greater than in the stammerer. The indifference on our part may possibly be explained by the fact that the treatment of these patients is not well carried out in the office, hospital, or sanatorium, but is best handled in the class room. The fact that we are not in a position to treat these patients, however, and do not know where to refer them, does not help the stammerer or excuse us. We should see that there are places, in every large city at least, where the stammerer will receive the kind of treatment we know is correct. This can be done by putting our seal of approval on the diploma of every teacher properly trained for this line of work.

It is a fact of no small significance that the school superintendents in fifty of our largest cities are almost unanimous in their opinion that the stammerer's plight is of sufficient gravity to warrant special attention in the public school. Several of them in fact have installed a department for the correction of stammering, where, if we were in a position to recommend a teacher of proper qualifications, the success of the undertaking would be assured. In some instances these departments are placed in charge of teachers whose special preparation was for work with the deaf. This is a misdirected effort, and naturally the results are not commensurate with the labor expended.

That the stammerer can be successfully handled in the public school there is no question. What is needed is the help and cooperation of the medical profession in encouraging the installation of a department for the correction of impediments of speech, to see that teachers for these departments receive proper training, and to furnish school boards with information regarding the stammerer.

Could the American Medical Association do better than to establish a department similar to the Volta Bureau maintained at Washington, D. C., by the American Association to Promote the Teaching of Speech to the Deaf? Through its bureau the efforts of this society have brought into use the most approved methods for handling the deaf in nearly all public and private schools where the deaf are being instructed. That the great majority of stammerers do not know where to turn for help other than to the institution of the quack is the condition present in the United States to-day. There is a sufficient number of stammerers to warrant the establishment of a special department for them in our public schools. The results are more brilliant than it is possible to obtain from other special lines of work, such as with the blind, deaf, and defective children. While the work may be greatly advanced by the medical profession, as individuals we are not prepared to handle this class of cases. That the stammerer is allowed to go uncorrected and that there is so little effort made to improve his condition is a disgrace, not only to our profession, but to the community at large.

It is my sincere hope that this body will take it on itself to inaugurate a movement which may be the means of encouraging and putting on a proper basis the correction of impediments of speech in our public schools.

121 Wisconsin Street.

ABSTRACT OF DISCUSSION

Dr. Elmer L. Kenyon, *Chicago:* The extremely important sociologic side of this problem, having to do not only with stammering, but also with other defects of speech, has never been adequately met, at least in the United States.

It is certainly true in Chicago, and doubtless in all other large cities, that there are thousands of children who have defects of speech which, if not corrected, are bound to make their success in life difficult and often impossible. It is also true that among this great number of stammering children, a large percentage have not enough means to pay for the rather expensive private teaching which they must have. It is also to be said in this conne[illegible] that, even if one with defects of speech has money [illegible] ike [illegible], there are comparatively few places [illegible] ted [illegible] re he can go and have competent as[illegible] st [illegible] Not only because the problem is a [illegible] len[illegible] lly, but also because if it is ha[illegible] ysic[illegible] be handled honestly, I think tha[illegible] pr[illegible]

concern itself with this disorder. So far as the sociologic problem is concerned, treatment should be undertaken in the schools by all means. Speaking with some reservations, I think that this is where it belongs. The children must go to school, and, therefore, they can all be reached and reached early, which is of great importance. If I had any critical remark to make about Dr. McBeath's paper, I think it would be that, perhaps, he did not emphasize the difficulties of curing stammering so much as he might rightly have done, though I am sure that he understands them. These difficulties apply especially to the fully developed cases. Stammering begins ordinarily just before or just after the child goes to school. There should be machinery ready in every city to perform the task of preventing the further development of the stammering if when the child first enters school he shows a tendency to do this. The difficulties to be overcome are not small, but the needs warrant the effort. Behind such an effort there should be competent medical and psychologic oversight.

Mrs. Frank Reed, Detroit: I have been in this work for twenty-five years. I believe that no class of afflicted people has been so imposed on by unscientific and unskilful treatment as the stammerers. The time has come for scientific men to look into this subject and to advise and educate the public. The average person—parent, physician or teacher—feels that the child will outgrow its speech defect. Teachers generally do not know what to do, and say to the stammering child, "Hurry up, say what you have to say or keep quiet." This embarrasses him; his mind becomes centered on his difficulty and it grows. Public schoolteachers do not understand stammering children and do not know how to train them. They go to some school and observe a class for a day, or ten days, or read some fake advertisement and think that they know all about the method of treatment, and then they try it on the children. This is not fair to the children. The difficulty in correcting stammering is great, but it can be overcome. We should recognize the difference between difficulties and impossibilities. Just because a thing is difficult is no reason why we should not undertake it, but it is a reason why teachers who undertake to correct stammering should have a thorough scientific training in the mechanical and psychologic processes of speech. The subject of fear enters largely into the training of these children. If the child is taught by a competent teacher to keep his emotions under the control of the will, the result will be more satisfactory. Statistics show that most of the stammering occurs during the school age. The teacher excites the child, or does not know how to handle him. It is time that teachers have the proper training in order not only to correct, but also to prevent the misery. When these children are relieved of their difficulty they are normal. We spend thousands of dollars in our schools for training defectives, and when all that is possible has been done for a thousand of them, it does not equal the benefit to one cured stammerer.

Dr. Thomas J. Heldt, Columbia, Mo.: As Dr. McBeath has pointed out, this is really a school problem. If we could have the children under medical inspection from the beginning of school life, we should be able to select those who could not be cured by proper training by a competent teacher. If, while under the specially trained teacher, there is no improvement, then the real cause of the trouble has not been disclosed and the stammerer's fear has been improperly approached. Dr. McBeath, in speaking of this fear, said that it was the source of great anguish to the stammerer. Just what is it that lies back of that anguish? Dr. McBeath referred to it as the fear of stammering. I think that it is not only the fear of stammering, but also something deeper. Cases treated by the Freudian method have brought out surprising results and suggest that it is some incident in that child's or adult's life that is the cause of this fear. I call to mind a case seen recently—a young lady of 19. There is only one time when she stammers, and that is when she is introducing a friend. Then she is worried and flustered. The thing lying [illegible] of that disturbed state is not simply the fear of not [illegible] able to select the right words and make the introduction properly, but probably some incident in her life that must be approached by psycho-analytic methods. I believe that psycho-analytic treatment promises worthy results in these cases.

DR. TRUMAN W. BROPHY, Chicago: It seems to me that our duty lies in the direction of doing all we can to place persons who are thus afflicted in the hands of those who are eminently prepared to correct the defect. Other defects, aside from stammering come into our experiences in the management of those who are not able to speak distinctly. For a long time I have been trying to help these persons by directing them to experts in phonation. Such teachers as Dr. Kenyon, Dr. Hudson-Makuen of Philadelphia, Dr. Scripture of New York and Mrs. Reed of Detroit are able to do so much to assist those afflicted in this way, help them out of their difficulties and put them in a position to go through life as others do, that I feel that we should recommend these persons to them for treatment.

DR. A. T. RASMUSSEN, La Crosse, Wis.: I devote a good deal of time to the practice of facial orthopedia, commonly known as orthodontia. A case comes to my mind of a bright boy, 15 years old, whose parents brought him to me stating that he stuttered, and asking that, if possible, I find a reason for it. They said that he stuttered seldom, but that when he did, it was very bad. There seemed nothing wrong about the boy's condition except some slight oral defects. I performed an oral operation, correcting a slightly undeveloped maxilla, and gave the boy a great many suggestions. He does not stammer now. Whether it was altogether the suggestion, or whether it was the treatment, or whether it was a combination of the two, I am not prepared to say, but I think that we should take into consideration the possibility of this defect being due to some pathologic condition in the mouth.

MRS. FRANK REED, Detroit: I think that the gentleman who has just spoken has made it quite clear to us that any physical defects which are present should be corrected, and that possibly such correction would give the child a suggestion that he can talk all right when he has learned the process of speech.

DR. H. F. MCBEATH, Milwaukee, Wis.: Dr. Kenyon and Mrs. Reed have made clear to you the disadvantages to the individual stammerer, and Dr. Brophy makes the suggestion that they be sent to eminently able people for correction. Knowing the number of stammerers in this country, we see that but a small fraction can be handled by the few who are capable of doing the work. What is needed by the schools is an outline of the principles which should be followed so that the teachers shall not be permitted to continue experimenting. In twenty-six cities in the United States the number of stammerers in the schools is not even known. In twelve cities the schools are attempting to do this work and are getting good results through their special teachers.

Nearly all of the school superintendents from different parts of the country in answering my questionnaire express themselves as seeing the need in the near future of establishing a department for the stammerer. It seems to me that the American Medical Association might outline a superior method which would be a great help to these educators.

Underweight Schoolchildren.—In one of the public schools in Philadelphia, Walter W. Roach found that ten pupils between 6 and 7 years of age were 62 pounds underweight, or an average 6 1/5 pounds per child; eighteen pupils between 7 and 8 years were 110 pounds underweight, or an average 7 11/16 pounds per child; fifteen pupils between 9 and 10 years were 93 pounds underweight, or an average 6 1/5 pounds per child; sixteen pupils between 10 and 11 years were 165 pounds underweight, or an average 10 1/3 pounds per child; six pupils between 11 and 12 years were 58 pounds underweight, or an average 11¾ pounds per child; twelve pupils of 13 to 14 years were 167 pounds underweight, or an average 14 pounds per child.—Paper read at Buffalo Congress on School Hygiene.

A METHOD OF CLOSING A SINUS BETWEEN THE ANTRUM OF HIGHMORE AND THE MOUTH *

L. W. DEAN, M.D.
IOWA CITY, IOWA

The topic with which this paper deals has been chosen for three reasons: first, because I have had so much difficulty myself in eradicating these sinuses; second, because I see so many sinuses left after others have operated; and, third, because a search of the literature has failed to furnish very much information regarding the technic of such a procedure. Since selecting the topic I have operated in twenty-three such cases. They were all cases of alveolar necrosis with antrum involvement, with the exception of two cases, or they were cases of permanent sinus following an operation for antrum suppuration secondary to alveolar necrosis. The two exceptions were, first, a large infected dentigerous cyst, lying external to the antrum. This was drained into the nose through the antrum. And, second, a case of composite follicular odontoma which was also drained into the antrum and through it into the nose. With the cases of alveolar necrosis and Highmorian empyema a Denker operation with the complete removal of the necrotic bone was performed.

Various methods for closing these sinuses were tried. Those tried at first gave uniformly bad results. The perfected operation gave about ninety-five per cent. good results. I will describe simply the technic of that part of the operation which was performed after completing the Denker operation, and also the various methods attempted in the order in which they were tried.

First, I removed the necrotic bone and then the inferior portion of the alveolar process. Just enough of the latter was removed to bring the periosteum of its inner and outer surfaces together. The two layers of periosteum were then sutured with interrupted sutures of black Chinese silk, No. 4. These sutures did not hold but tore out within a few days notwithstanding the fact that they were carefully cleansed every two hours with hydrogen peroxid.

Second, the periosteal flaps were prepared the same as before, and, using the same silk, by means of double-armed sutures the threads were introduced from within out, just above the bone. These sutures held better than the first but tore out in two or three days.

It was now manifest that the Chinese silk was not the proper substance for suture material. It would become soaked with saliva, swell, and naturally become crowded with micro-organisms. It was quite impossible to keep these sutures clean.

Third, silk-worm gut was substituted for Chinese silk as in the second method. These sutures could be kept clean and held several days longer than the others, but not long enough to secure healing. The silk-worm gut would cut through the mucous membrane and the periosteum.

Fourth, various substances as gauze, pieces of rubber tube, lead plates, etc., were placed within the loop of silkworm gut, on the inner surface of the alveolar process and a second piece placed underneath the outer ends before they were sutured. This was done with the hope of preventing the sutures from cutting through the membrane and periosteum. The pieces of gauze which are so successful in similar sutures on the skin could not be kept clean in the mouth and soon caused trouble. The lead plates were much more difficult to apply than the rubber tubing and had a tendency to cut the membrane. Whole pieces of small rubber tubing or pieces cut longitudinally in halves were used. These sutures would hold nicely for from five to seven days when they would tear out and the sinus would be reestablished but not so large as before.

---

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

It was evident that the cause of our trouble was not now due to the suture but to the fact that sufficient bone was not removed to allow apposition of the periosteum without too much tension on the suture.

Fifth, the method which I consider the very best was used. It is the one that we have used in the last half of our operations and while it has not been successful in every case, it has given us 95 per cent. good results. The method is as follows: After completing the Denker operation and being sure that there is excellent drainage into the nose, the alveolar process is attacked. After removing the necrotic bone completely, enough of the inner and outer lamella of the alveolar process is removed to allow of perfect apposition of the flaps that have been previously lifted from its inner and outer surface. These flaps must come nicely together so that it is not necessary to have any tension on the sutures. Then I place along the inner and outer surfaces of the alveolar process at this point a piece of small rubber tube sufficiently long to allow it to be tucked underneath all the sutures; then using double-armed silkworm-gut sutures, a sufficient number are introduced from within out, the loops resting on the rubber tube on the inner surface of the alveolar process, the knots being tied on the rubber tube on the outer surface of the alveolar process. Care should be exercised to tie the sutures just tight enough without getting them so tight as to produce pressure-necrosis of the flap. These sutures are cleansed hourly with hydrogen peroxid following the operation. The nurse must be exceedingly careful to clean in and around the sutures and tube thoroughly. If this operation is done at the time of the antrum operation the incision for the Denker operation is made high up and is entirely separate from the incision on the border of the alveolar process. The periosteum, from the outer surface, is elevated completely without being torn and handled with great care while the necrotic bone is being removed and the inner and outer lamellæ of the alveolar process are being cut down.

With every case of necrosis the operator must exercise his individuality in making the cut on the border of the alveolar process so as to get the best possible apposition of periosteum. The results of this operation have been surprisingly gratifying to me. As a rule the wound margin remains clean, the sutures remain clean, and when they are removed on from the seventh to the tenth day leave behind a well-healed wound. When I attacked this problem last summer I did not expect such gratifying results. It is an operation that I can recommend for trial.

ABSTRACT OF DISCUSSION

Dr. Thomas L. Gilmer, Chicago: I should like to ask Dr. Dean if the operation he described for curettement of the maxilla is not similar to the Caldwell-Luc operation.

Dr. Dean: The Denker operation differs from the Caldwell-Luc in that the incision is on the anterior wall of the bone. It is practically the same operation.

Dr. Truman W. Brophy, Chicago: I congratulate the author on his success in closing the sinus, but in my experience the greatest difficulty is in keeping it open. Most surgeons find it difficult to keep it open until the cavity is in a healthy condition. When I succeed in doing this, I always feel that I am fortunate.

The question of sutures within the mouth has been to me one of the great problems. In my earlier experience I had the same results with silk that Dr. Dean has had; I therefore abandoned long ago the use of anything in the mouth that would absorb the secretions, using only silver and horsehair sutures and lead splints. I have had trouble in finding horsehair that could be relied on for sufficient strength for this purpose. It may be kept in the mouth a month, if necessary, without causing any irritation.

Dr. G. V. I. Brown, Milwaukee, Wis.: Some time ago I was operating where they had the most satisfactory horsehair that I had ever used. The hospital authorities took the hair out of the tail of the ambulance horse and boiled it. Prepared in this way it is soft and pliable and not brittle. Sometimes, however, I have found it treacherous. We never have had any infection from it in the hospital, where it has been used a long time.

Dr. C. H. Oakman, Detroit: In antral cases in which the palatal bone is necrotic I seldom find it necessary to divide the soft tissue overlying the hard palate, but rather cut high above the teeth or amputate the roots of the molars or bicuspids, making a wound sufficiently large through which to remove the necrotic bone. Within the last eight months I have successfully treated four or five cases in which a portion of the palatal bone was necrotic in this manner. In chronic cases, in which the adjacent sinuses are liable to be involved, I fit a vulcanite plug into the wound. This is held in place by the cheek and affords the necessary drainage. In this way the topography of the palate is little affected, which I believe to be of the utmost importance.

Dr. Truman W. Brophy, Chicago: About three years ago I found that the hair of the tail of a bull is much softer, larger and stronger and will endure a great deal more tension than horsehair. It sustains 25 per cent. more weight than horsehair.

Dr. L. W. Dean, Iowa City, Iowa: I appreciate the discussion regarding the kind of horsehair which should be used. I did not mention the use of horsehair in my paper. It was tried, but its quality was so poor that it gave no satisfaction.

THE SURGERY OF INFANTILE PARALYSIS*

EDWIN W. RYERSON, M.D.
Professor of Orthopedic Surgery, Chicago Policlinic; Assistant Professor of Orthopedic Surgery, Rush Medical College (University of Chicago)
CHICAGO

During the early days after an attack of acute anterior poliomyelitis there is usually little to be done except to make the patient as comfortable as possible. Pain is often so severe that massage and electricity cannot be used, and the only important detail of the treatment is the careful prevention of deformity.

This paper will deal only with the treatment of paralysis of the legs and the trunk, as paralysis of the arms is much less frequent, and would require too much additional time to consider.

The most common deformity following infantile paralysis is the dropping downward of the foot at the ankle-joint, pes equinus. In some cases this is not due to a permanent paralysis of the anterior tibial muscle and the toe extensors, but to the fact that in many instances the attending physician takes no measures to hold the foot at a right-angle during the first few months after the attack. As a general thing the patient is confined to the bed for some weeks or months, and the usual position in bed is with the feet pointing downward nearly or quite in the same line as the leg. The return of power, in cases in which motor power actually does return, is often too slow and gradual to balance the structural shortening of the gastrocnemius and soleus, and by the time the full power has returned the Achilles tendon is too short to permit of dorsal flexion.

---

* Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Although the shortening is not actually in the Achilles tendon itself, but in the muscle fibers, custom has sanctioned the use of the term "shortened tendo Achillis." This shortening, which generally requires an operation for its relief, can be and should be always prevented, either by a light splint of the Volkmann variety, or by a posterior molded plaster-of-Paris splint, or some similar apparatus, easily removable for the daily massage and passive and active movements. By such treatment, many patients will recover a considerable degree of muscular power which would otherwise either be lost entirely or regained much later by the aid of operative interference. In a similar way, contracture deformities at the knee must be carefully prevented, either by suitable splints or by weight and pulley traction. Contracture of the tensor vaginae femoris (tenso fasciae femoris), which is an extremely difficult deformity to treat in its later stages, can be readily prevented, in most instances, by not allowing the leg either to rotate outward or to be abducted at the hip. Hoffman's work in this line is well worthy of attention.

In case, however, that some or all of these deformities have occurred, radical treatment is necessary. If the case be recent, forcible manual correction, with or without an anesthetic, may prove successful, especially if done by degrees at several sittings. A removable cast or a simple brace must now be worn until either the recovery is complete or until the time for radical operation has arrived. Every effort must be made to induce the patient to use actively all the weakened muscles during regular exercise periods every day. In small children considerable ingenuity may be required to devise exercising games and to stimulate the patient's interest and cooperation. Massage is of value, and galvanic electricity may be of some assistance. The faradic current is useless.

This line of treatment must be carried out until the period of spontaneous repair, or the probationary period, has been passed. This period is not a definite one. It is not probable that any improvement in the condition of the ganglion-cells in the cord will occur after the lapse of a year, but it is perhaps possible. It is my custom to postpone operative interference, so far as practicable, until two years after the attack. During this two-year period, however, some of the contracture deformities may become so powerful that the braces or apparatus can no longer control them. It is necessary in such cases to perform conservative tendon-lengthening operations, although it is always advisable to avoid them whenever possible until the probationary period has been passed.

CORRECTION OF LATE DEFORMITY

This must be done in all cases before the radical operation is performed, but can in most cases be done at the same sitting with the radical operation in children. It consists most frequently, as a matter of practice, in the lengthening of the Achilles tendon.

While in cases of congenital club-foot a simple transverse tenotomy is perfectly safe and satisfactory, increasing experience has led me to prefer an open lengthening of this tendon in cases of both flaccid and spastic paralysis. One patient with poliomyelitis and one patient with spastic cerebral paralysis on whom subcutaneous tenotomy was performed in this clinic have had loss of function because of too great lengthening of the tendon, and have required secondary operative shortening. Waterman and Hibbs have reported similar cases. This tendon should, then, be lengthened by the simple step method, and sutured with fine silk. No variations of this method offer any advantages over it. The methods of Bayer and Gocht are ingenious, but no better. The sheath should always be restored by suture.

In many cases other work than lengthening the Achilles tendon may be necessary. All existing deformities must be corrected by suitable means, such as manipulations, forcible redressment, and even operations on the bones. If such work be neccessarily of much severity, it may be well to postpone the more delicate operative procedures until all reaction has subsided. This is especially advisable when oozing blood from bony surfaces necessitates temporary drainage, and also when the skin incisions have been unavoidably placed where they would lie directly over the site of a tendon transplantation or silk ligament insertion.

In pes equinus it is often wise to lengthen the toe flexors in addition to the Achilles tendon. The simplest way to do this is to plunge a small tenotome into the sole of the foot at the base of each proximal phalanx, feel for the tendons with the flat of the blade, and then divide them while the toe is dorsally extended. This will divide both the long and the short flexors.

Knee contractures offer more difficulty than foot deformities, from the fact that in many cases of long duration the leg cannot be straightened without endangering the vessels and nerves. If circumstances will not permit the gradual correction of the deformity, it becomes necessary to shorten the femur. Since we desire a movable joint, it is not wise to resect the articular surface. A section of the femur can be removed just above the epiphysis, and the epiphysis moved upward and reattached to the shaft. This operation will be found of service in other conditions than anterior poliomyelitis, and has the advantage of sparing the articulation, while affording any desired shortening of the femur.

Old contractures around the hip are most frequently those of flexion and abduction. These may require radical operations. The tensor fasciae latae, the rectus femoris and sometimes the iliopsoas must be cut by open incision. If adduction be present, subcutaneous myotomy and forcible stretching will generally give satisfaction.

The deformities of the spine cannot at present be benefited by operation, and can be treated only by forcible correction and retention in molds or braces. Abbott's method of correction is of considerable aid.

I now come to the problem of retaining permanently the correction already attained. It is a matter of everyday experience that the simple correction of the deformities due to infantile paralysis does not affect a permanent result. No matter how thoroughly the tenotomies and redressments are done, no matter how long the correction is maintained by apparatus, relapse will surely occur when the apparatus is removed. In this particular a paralytic club-foot, for example, differs intrinsically and radically from the ordinary congenital club-foot. In the latter, the congenital variety, redressment, tenotomies and retention in plaster casts or braces will effect a permanent cure in a reasonably short time. In a paralytic club-foot of precisely the same general appearance, the same treatment will be effectual only while the casts or braces are being used. Almost immediately after the apparatus is abandoned the foot will begin to relapse into its previous deformity. Unless we are willing to condemn the patient to a life of constant brace-wearing, we must provide active or passive antagonists to prevent the healthy muscles from pulling the limb toward themselves.

TENDON TRANSPLANTATION

When enough muscles remain unparalyzed, tendon or muscle transplantation will give excellent results if properly performed.

The two principal methods to be considered are those advocated respectively by Vulpius of Heidelberg and Lange of Munich.

In the Vulpius method, the entire healthy tendon, or a portion of it which has been partially split off from it, is sutured to the tendon or muscle which it is intended to strengthen. This method and its modifications have been so extensively used by Vulpius and his followers that there would seem to be little doubt of its efficacy. In my experience, however, it has been found of value in only a limited field. It is useful, particularly in the arm and forearm, and in supplying power to the flexors and extensors of the toes, but when used where a considerable strain is to be thrown on it, as in the tibial or peroneal muscles, it shows a tendency to lose its efficiency. This may be due to the stretching of the paralyzed tendon, but in many cases cannot be referred to any definite cause. The operation is technically easier than the method of Lange, but it is not so certain in its results.

After a considerable experience with the method of Vulpius, I began, some years ago, to use the periosteal implantation of Lange. This gave satisfaction in many of the cases in which tendons were transplanted, but proved not strong enough for the silk suspension cords or ligaments used in cases of drop-foot. In a number of instances a gradual slackening was noticed in the silk ligaments, which caused an annoying return of the drop-foot position. It was not known just where the weakness lay until a few months ago, when one of my cases seemed to supply a solution. A boy of 7 had been operated on nearly two years ago for paralytic drop-foot. A heavy braided silk cord, size 14, was woven into the periosteum over the base of the first metatarsal and the inner cuneiform, and then carried up under the annular ligament and tied into a hole bored into the tibia. A year ago the foot was found to have dropped again so that it was difficult for the patient to walk. The silk was cut down on and a strong pull was made on it to determine the strength of the attachments. To the operator's surprise, both attachments seemed perfectly firm and strong. The silk had become covered with a dense, glistening covering, which could be readily peeled off. The cord was cut, and tied together again so as to shorten it enough to bring the foot up once more to a right angle with the leg. In spite of this, however, a gradual dropping once more began after the cast was removed, and about three months ago the lower end of the silk was dissected out. The loop of silk which had been woven into the periosteum was found to be nearly 1½ inches from the place in which it had originally been inserted. There was a strong fibrous band from the loop of the silk to the inner cuneiform bone, evidently the stretched and hypertrophied periosteum which had gradually been pulled up and elongated by the weight of the foot. It looked very much like normal tendon tissue. Sometime before this evidence was obtained, however, I had abandoned the periosteal fixation method in the silk ligament suspensions, and had practiced the insertion of the silk directly through drill-holes bored in the bones of the foot as well as the tibia.

The Codivilla method of nailing the tendons to the bone is not so reliable as the direct suture with silk.

TECHNIC

Since drop-foot is probably the most common deformity due to infantile paralysis, it seems proper to describe in detail the operative procedures for its relief.

When the anterior tibial muscle is the only one paralyzed, the extensor longus hallucis will make a satisfactory substitute. A curved incision is made over the inner border of the foot and the tendon cut opposite the base of the first phalanx. A hole is bored with a 1/16-inch drill through the base of the first metatarsal bone, and a loop of strong silk is passed through by a needle. The end of the tendon is laid in the loop, and the loop and tendon pulled through the bone. The foot is held at a right angle, and the tendon pulled taut. The free end of the tendon is then passed through a slit in the "standing part" of the tendon, and is then itself split and the ends brought around the standing part and sewed with several interrupted fine silk sutures. This firmly anchors the tendon to the bone, and provides a useful extensor for the tarsus. The distal end of the toe extensor can be sewed to the tendon of the second toe to prevent toe-drop.

In cases in which there seems need of a more powerful extensor of the foot, the extensor tendons of the four smaller toes can be braided together and sutured to a loop of silk passed through a hole bored in the fourth or fifth metatarsal bone.

If the toe extensors are paralyzed, the peroneus longus, the tibialis posticus or the toe flexors can be passed through the interosseous space and sewed into the tarsus or metatarsus. The results are seldom entirely satisfactory when tendons are passed through the interosseous space, probably because adhesions are more likely to occur. I have often passed the peroneus longus around in front of the tibia just under the skin, with excellent function, although the dorsal flexion is apt to be combined with outward deviation of the foot. Usually, if possible, the tibialis posticus or a toe flexor should be similarly carried around the tibia, to correct this deviation.

Splitting of the gastrocnemius, in an endeavor to procure a division of function and thus making two separate muscles of the gastrocnemius, has been an entire failure in all of the cases in which I have operated.

When so many muscles are paralyzed that transplantation is not feasible, the foot can be made useful by permanently checking the foot-drop. Several methods may be used, of which arthrodesis is perhaps the best known. I have done about thirty operations of this kind and the results have been far from satisfactory. It should never be done in children under 14 by the ordinary technic, for bony union is very uncertain below this age.

In any case, the feet are nearly always painful for a long time after the operation, and the absence of dorsal flexion causes inconvenience, especially in walking uphill. It is possible that better results may be obtained by cutting a bone-spike from the tibia and driving it upward through a hole bored through the os calcis and the astragalus, and up into the tibia, but I have not as yet used this method. Lexer has reported good results with it.

SILK LIGAMENT SUSPENSION

It is much more satisfactory, and it is easier and safer, to suspend the foot at a right angle by heavy silk cords running from the tibia downward in front of the ankle to the bones of the foot. This operation has been widely used by Bradford, Soutter, Allison and others in this country. When done by the proper technic it affords a strong and painless foot which is held at or near a right angle and is capable of passive dorsal flexion. The operation can be modified to control any lateral deviation, varus or valgus, and by the addition of posterior cords can control calcaneus deformity. I have done a large number of these operations during the last five years, and although by the older methods some of the earlier cases proved disappointing, the present technic can be relied on to give satisfaction.

TECHNIC

A curved incision with its convexity downward is made from just below the scaphoid to the middle of the inner metatarsal bone. The flap is retracted, and the soft tissues are dissected away from the proximal end of the metatarsal bone. A drill-hole is bored in the base of the metatarsal, and through it is passed a braided silk cord, size 12 to 16, previously boiled in a 1:1,000 solution of mercuric chlorid. The cord should be 20 inches long, for easy handling. It is pulled through to its middle, and a loose single overhand knot is tied just above the bone to keep the two strands close together. The ends are then threaded into a long eye in the end of a Bessemer steel wire probe about 3/32 inch in diameter. This probe is stiff enough to stand a considerable strain, but can be bent as desired. The tendon of the tibialis anticus is now exposed at its insertion into the cuneiform and metatarsal, and a small slit is cut in the sheath. The probe, slightly curved toward the end, and carrying the silk, is passed into the tendon-sheath, and is forced gently upward under the annular ligament until it reaches a point on the tibia 2 or 3 inches above the ankle-joint. A curved incision is made over the tibia at this point, and the end of the probe is pushed out through it. This is easily done with the steel probe, but is much more difficult with the ordinary silver or copper probe. The silk is now pulled out of the eye of the probe and clamped with a hemostat for purposes of identification.

A similar operation is now performed on the outer side of the foot, the fifth metatarsal being drilled and threaded with a similar silk cord, which is then passed up the sheath of the peroneus tertius tendon and made to emerge from the tibial incision. A drill-hole is now bored through the crest of the tibia, and one cord of each of the pairs of cords is passed through it by means of a large needle. The pair of cords from the inner side of the foot is now pulled tightly enough to bring the foot to a right angle, and tied with a triple square knot. The outer cords are now tightened enough to bring up the external border of the foot to the same level, and likewise tied. This now holds the foot firmly, and the incisions are closed. It is well to sew the subcutaneous soft tissues over the silk cords as a separate layer, and to suture the skin very carefully. A plaster-of-Paris cast is applied, and removed in about two months, after which there is usually no further need of external support. In cases of marked varus, the silk cords from the outer metatarsal are fastened into the fibula instead of the tibia.

OTHER OPERATIONS

Four cases of pes calcaneus have been treated by lengthening the semitendinosus with heavy silk and inserting the silk into the os calcis. There has been some benefit in all of these cases, and the operation seems worthy of more extended trial.

When the quadratus is paralyzed, and the hamstrings are strong, excellent results can be obtained by transplanting the biceps and semitendinosus forward into the patella. This is one of the most satisfactory operations within the range of tendon transplantation. The two hamstrings must be dissected upward for a long distance through separate incisions, heavy silk cords woven into them, and a wide opening made in the subcutaneous fatty tissue for their passage. The silk cords should be threaded through drill-holes in the patella, the tendons pulled down to the patella, and the cords tied. Several interrupted silk sutures are also used to sew the tendons to the surface of the quadratus. It is not necessary to insert the cords into the tubercle of the tibia.

This operation is also of benefit in some of the cases of spastic paralysis in which undue flexion of the knee is present.

I regard the use of the bichlorid silk as one of the marked advances in this department of surgery, and I feel that great credit is due to Lange for his advocacy of this technic. The silk rarely causes trouble when properly used, and can apparently remain indefinitely in the tissues without losing its strength or acting as a foreign body. So far, it has not seemed necessary to paraffin the silk, although this is advised by Lange.

The use of intra-articular silk ligaments had been practiced by Bartow and Plummer to produce limitation of motion in cases of partial or total paralysis. The cords are passed through the bones and joints in such a way as to make a partial stiffening of the joint. This method deserves trial, but I have not as yet attempted it.

NERVE TRANSPLANTATION

The work of Hans Spitzy in the grafting of nerves seemed to offer new possibilities in the treatment of infantile paralysis. It is obvious that successful nerve-grafting would attack the trouble at almost its very source, and would be far better than any peripheral operations on the muscles or tendons. The method advocated by Spitzy was to make a small slit in the nearest healthy motor nerve of sufficient size, and to implant in this slit the distal end of the paralyzed nerve. The technical difficulties are often not great, and require merely care and precision. About six years ago I operated in nine cases by the method of Spitzy. Seven of these were cases of paralysis of either the external or the internal popliteal nerve as a whole. In another case the musculocutaneous was grafted into the anterior tibial, and in the last-named case the musculocutaneous nerve of the arm was inserted into the median. None of these operations was followed by any actual nerve regeneration that could be demonstrated.

These results seemed so discouraging that I have so far made no more attempts of this kind.

Vulpius and Stoffel report some rather encouraging results by a highly interesting and complicated method by which the various nerve-fibers are differentiated at operation with electric stimulation. This would afford an opportunity for the end-to-end anastomosis of suitable nerves, which would be more logical than Spitzy's technic. Their recommendation to perform such operations within six months after the attack, however, should not be followed.

CONCLUSION

I believe that far too little surgery is generally done in cases of infantile paralysis, and that nearly all cases can be benefited by properly planned and properly executed operations.

In a single paper of this length the subject can be only sketched lightly, and the intention has been to call attention to a few of the more useful operations which have stood the test of time and experience.

122 South Michigan Avenue.

ABSTRACT OF DISCUSSION

Dr. E. A. Rich, Tacoma, Wash: For the last few years I have been much interested in this line of work and wish to attest its efficacy. If judgment is used in the diagnosis of the pathology present and in the selection of the proper corrective procedure, and if the work indicated is skilfully performed, the condition of the limb should be bettered. In some patients not suffering extensive muscular losses, the restorations after wise surgical measures are often marvelous. While the leg cannot be made so large or so beautiful as the normal leg it is always possible to restore all or part of the function.

Dr. F. J. Gaenslen, Milwaukee, Wis.: I was interested to hear Dr. Ryerson's frank report regarding his experience with neuroplasty. When abroad last summer, I paid particular attention to this procedure in infantile paralysis. Dr. Spitzi of Graz operated on one patient while I was there, but unfortunately I saw none of his late results. Dr. Putti of Bologna said that Spitzi had operated on three patients for Dr. Codivilla in Bologna, and that in none was there any improvement to be detected by careful examination at the end of two years. There seems to be a lack of interest in neuroplastic methods in recent years. I have had only a limited experience with silk ligatures for drop-foot, etc., but cases of this kind that I have had have been satisfactory. I used bichlorid silk. In one case the large knot caused a pressure sore on the outside of the tarsal bones. That granulated over, however, and gave no further trouble.

Dr. Roland Meisenbach, Buffalo, N. Y.: Dr. Ryerson's excellent work in this connection has brought many ideas to my mind. The use of silk has been well established for tying purposes. In employing the silk for the purpose of substituting tendons or ligaments, we should consider carefully whether we have to deal with an actively growing epiphysis, as in children, or not. This does not hold good so much in drop-foot as in deformities in other parts of the body, for instance, the knee-joint. Implanting silk ligaments may be temporizing only.

Dr. Ryerson made the statement that silk remains indefinitely in the tissues. I cannot altogether agree with him in this regard. Several years ago I had occasion to make some experiments in regard to silk and catgut in tissue. The cross section showed that the catgut readily absorbed. It required for silk, however, a longer time. The first process was to bring to it many leukocytes, and then slow absorption took place. I can readily understand what becomes of the silk in cross section, but I should like to know Dr. Ryerson's theory in regard to the lengthening of these fibrous bands or ligaments, as the child grows older. Silk is unelastic, and I think that it makes little difference whether one uses braided or twisted silk. Lange, I think, uses braided silk. I have been employing silk substitutes for tendons in selected cases only, as I do not believe that it is the ideal method of procedure in many cases of infantile paralysis.

Dr. Nathaniel Allison, St. Louis: Dr. Meisenbach has brought up the question that interested me a great deal in doing this work; that is, the ultimate fate of these silk strands and ligaments. I undertook to find out primarily what took place by introducing silk strands into the tendon-sheaths of dogs. I had one animal that carried such a strand in his tendo Achillis sheath for five months. On section of that tendon, I found that the tendon-sheath had proliferated to a marked degree and that the silk was infiltrated with cellular elements to a great extent. So it seems to me that this might answer, in a way, the question asked by Dr. Meisenbach concerning the fate of these ligaments. This was braided silk. If the process should go on and the silk become absorbed, it seems probable that a fibrous band would be left, which might be serviceable as a ligament. That is my idea, at least.

Dr. Edwin W. Ryerson, Chicago: I said that the silk apparently remains indefinitely in the tissues. That does not mean much, because I have only about five years to report on in my cases. In all of them that I have been able to trace, in which the operation took place five years ago, the silk is still there. There has been a marked increase in its size, which is, of course, due to the connective tissue forming around it. It has, so far, shown no signs of being absorbed.

Many operators use twisted silk instead of braided silk, but it is not so strong, compact or rigid. I have seen no specimens presented to show the actual absorption of the silk, and I do not believe that it will occur. I do, however, believe that in some cases the silk may be worn through after a time; but you have seen the picture of the woman in whom it has been in place for two years, with a great deal of strain on it. In this case, four large No. 16 cords were used, and they are apparently still there.

I think that Dr. Meisenbach wanted to know what happens when the leg grows and the silk does not. Of course, the silk does not change its length, and I have been interested in speculating on the ultimate result in such cases. As you know, the majority of growth in the tibia—three-fourths of it—takes place at the upper end. I do not place the silk much above the lower epiphysis, where only one-fourth of the growth occurs. The growth would be likely to cock the foot up in the air, but this has not as yet happened in any of my cases. In some cases in which periosteal implantation was done, the foot has dropped down on account of periosteal stretching. If the silk ligaments should become too short, one might do a tenotomy and lengthen them, or put in a lengthening piece of silk.

If the subcutaneous tissues are sewed thickly over the site of the knots, they will seldom give any trouble. Of several hundred cases, I have had the silk give trouble in but three. In two of these, the silk came out. This was due to a stitch-abscess. In the other, there was a deep abscess and a small piece of silk came out. These were tendon transplantation cases. In only one case has a silk ligament given any trouble.

ACIDOSIS AS A COMPLICATION AFTER SURGICAL OPERATIONS *

W. B. RUSS, M.D.
SAN ANTONIO, TEX.

No length of training in surgical technic, no amount of experience in the operating-room, can make a competent surgeon of any man who is poorly equipped in the theory and practice of general medicine. The practitioner of surgery who loses interest in the problems of internal medicine becomes in time but little better than an overrated and overpaid mechanic plus a deficient surgical judgment and minus a surgical conscience; yet many of our surgeons of great note and most of the lesser lights struggling for recognition actually boast of their ignorance of, and lack of interest in, any branch of medicine outside the immediate scope of their special work.

It is small wonder, then, that the men engaged in other lines of work, particularly the neurologists, complain that most of the so-called neurasthenic patients they are called on to treat present abdomens decorated with scars marking the sites of operations that have made worse the conditions they were designed to relieve. Unwarranted operations, with the resulting cost in suffering and heart-breaking disappointment and the discredit cast on the profession, are bad enough, but there is yet another and a graver indictment against the surgeon who through ignorance or carelessness fails to study his patients before taking them to the operating-table. I refer to his failure to recognize in a large percentage of chronic cases certain symptoms that bear no close relationship to the conditions for which he proposes to operate, but are veritable danger-signals warning him of the existence of some more or less grave constitutional state, some serious disturbance of metabolism, which for the time at least renders the patient an extra hazardous risk for a general anesthetic, and yet with proper attention may be cleared up and a serious danger averted.

---

* Read before the Section on Surgery, State Medical Association of Texas at San Antonio, Tex., May 8, 1913.

The handling of a surgical case may arbitrarily be divided into:

1. The examination and diagnosis.
2. Preparation for the operation.
3. The operation.
4. The postoperative care.

The examination and diagnosis, requiring in many cases by far the greatest amount of learning and skill, are often treated in a perfunctory way. The case not infrequently comes into the surgeon's hands with the diagnosis already made and the operation planned by the family physician, who may or may not be a competent man. The surgeon too often accepts this diagnosis almost without question and merely confirms it with a few leading questions covering history of the local condition for which operation is proposed, and then after a limited physical examination and a partial urinalysis to determine the specific gravity and the presence or absence of albumin and sugar, directs that the patient be given the "usual preparation for operation," meaning the routine in vogue at the hospital and applicable to all cases without special reference to the peculiar needs of any one case.

The operation receives the only serious attention given by the surgeon himself, and fortunately the modern hospital technic and skilled assistants and nurses render this work safe as far as infection, hemorrhage and shock under ordinary circumstances are concerned. The hospital routine and skilled nursing furnishes all the after-care needed for ordinary cases. In any event, it is all that the patients are likely to receive. If at the operation the diagnosis is found to be correct, and, the patient's condition is in other respects satisfactory, the result will, of course, be all that could be desired. If, however, an innocent appendix has been removed, a harmless gall-bladder drained, a gastro-enterostomy done for chronic reflex pyloric spasm, or an unoffending uterus or a harmless movable kidney fixed in a position that will give rise to real symptoms instead of imaginary ones, as before the operation, surgery has merely been discredited once more, and the patient and the patient's friends disappointed and subjected to needless expense and heartaches.

This certainly is not to be desired and the surgeon deserves the censure of all right-minded persons. If he deserves censure for his carelessness in failing to exhaust every available means to arrive at a correct diagnosis before subjecting the patient to the fearful ordeal of a surgical operation, what are we to say of his failure to note in his patient's history and present condition a symptom-complex which could not possibly be accounted for by the local conditions, which clearly points to some perverted state of metabolism, and may constitute a serious menace to the chances for an early recovery, if not, indeed, a danger to life? Suppose, for example, that the patient has been starved by an improperly balanced diet, deficient in carbohydrates and consisting chiefly of proteins; has been starved and exhausted by prolonged diarrhea or vomiting, or has been a victim of so-called food terror in which he or she voluntarily refrains from taking proper food in sufficient amounts; or suppose that the patient is suffering from some toxemia, the result, perhaps, of chronic intestinal indigestion with constipation; the prolonged ingestion of some poison such as alcohol or tobacco, or drugs such as the salicylates, or is the victim of a toxemia resulting from some obscure organic disease as of the liver, pancreas or kidneys. The patient, let us say, is a young woman seeking relief for a chronic appendicitis. Suppose we confirm the diagnosis and advise operation, but fail to note that:

1. She has an abnormal dread of the operation and seems terror-stricken to an unusual and unaccountable degree.
2. She suffers from tachycardia and a tendency to dyspnea.
3. She complains of frequent headaches, vertigo and great mental depression.
4. Her breath has a peculiar sweetish odor, suggesting the odor of rotten apples.
5. Her extreme and peculiar nervousness has been sufficient to cause her family some anxiety as to her mental state.
6. The patient's urine is loaded with acetone, and therefore perhaps also with diacetic acid and beta-oxybutyric acid.

Failing to be warned, the surgeon allows this patient to go to the operating-table after the usual routine hospital preparation. The following account of what happens is familiar to us all.

1. The patient resists the anesthetic after the manner common only in such cases, and in alcoholics.
2. She vomits incessantly and the nausea persists for several days.
3. The pulse becomes rapid and often irregular.
4. She remains drowsy and stupid for an unusually long time after the anesthetic is withdrawn.
5. Her temperature may shoot up without apparent cause.
6. She is nervous and restless and suffers intensely, but does not tolerate an opiate well.
7. After a prolonged and anxiously watched convalescence the patient finally recovers.

This is the usual history, but some of these patients are not so fortunate. All the symptoms are much exaggerated. The patient does not completely regain consciousness, but after ten or twenty hours of persistent vomiting, rapid and irregular heart-action, a rising temperature, wild delirium or a more or less profound stupor, she dies.

A very little knowledge of internal medicine places us in possession of the following all-important facts:

1. These patients are the victims of some perversion of metabolism, associated with diminished alkalinity of the blood and the appearance in the urine of the acetone bodies.
2. They do not tolerate any general anesthetic, and most of them do not even tolerate opium or any other narcotic drug.
3. Large quantities of water, preferably carbonated, a diet of starches and sugars, preferably 5 or 6 ounces

of oatmeal with lactose daily, with alkaline laxatives and sufficient alkalies, such as sodium citrate or bicarbonate, to keep the urine neutral for four or five days, and frequent warm baths with friction of the skin will cause most or all of the symptoms to disappear in an astonishingly short time.

4. The condition will recur to some extent on very slight provocation, particularly after a general anesthetic, but can usually be forestalled by the use of alkalies and water by the mouth, by the bowel, or, in extreme cases, in a vein.

The significance of the acetone bodies in the urine has long been a matter of debate. It was at first thought that they were derived from glucose because of their appearance in diabetes. Then the origin was at a later date ascribed to the proteins, but according to A. R. Short of Bristol University, who has recently summed up all the available evidence, it is now definitely established that they are the result of a peculiar abnormal breaking down of fats. The physiologic process of dealing with fat is to resolve it into carbon dioxid and water with the liberation of heat; but when for any reason the tissues are unable to obtain sugar from the blood, fat is broken down with the production first of beta-oxybutyric acid, then diacetic acid and finally acetone. The relative amounts of these acids are dependent on the rapidity with which the breaking down of fats occurs. R. C. Cabot says that the appearance of the acetone bodies is due to a diminished utilization of carbohydrates because *(a)* sufficient carbohydrates are not ingested, *(b)* the sugar is not absorbed, or *(c)* the sugar is not assimilated.

The rôle played by the liver is not clearly understood, and it has not been demonstrated according to some authorities whether the fatty degeneration found in the liver, kidneys and other organs after death in these cases is the cause or the result of the acidosis. Apparently the acetone bodies are not in themselves poisons except in enormous doses. It would seem that the evil done is not due to any particular acid but rather to the reduction in the alkalinity of the blood. In the condition of abnormal catabolism of fats with the production of the beta-oxybutyric acid, diacetic acid and acetone, the body first relies on the reserves of sodium and potassium, but chiefly on the large quantities of ammonia, the result of the normal metabolism of the proteins. The ammonia combines with the beta-oxybutyric and diacetic acids and does not become converted into urea by the liver. Finally the supply of ammonia fails and the alkalinity of the blood falls, and a fatal termination results unless something is done at once to restore, at least in part, the normal reaction.

After all, we are not concerned with the many theories seeking to account for the appearance of the acetone bodies in the urine; but the fact that their appearance does indicate a serious perversion of the patient's metabolism and strongly contra-indicates the administration of a general anesthetic, until by appropriate treatment the patient becomes able to tolerate the anesthetic and to stand the operation, is of the greatest importance.

Every surgeon, of course, knows that certain nervous symptoms, such as abnormal fear of an operation, headache, a rapid pulse and a tendency to nausea usually indicate that the patient will not tolerate the anesthetic well and will probably suffer much from nausea and vomiting, restlessness and an unaccountable rise in temperature during the convalescence. My attention was first directed to the possibility of a fatal issue in exaggerated cases of this type about six years ago, when called in the following case:

Case 1.—A boy, aged 16, had been operated on three years previously for chronic appendicitis. He had suffered much from headaches, extreme nervousness and fear of the operation. The anesthetic given was chloroform. During the anesthesia his excitement was extreme and he had to be held on the table. He failed to react promptly and remained in a semistupor, with a rapid, irregular pulse and persistent nausea and vomiting. A specimen of urine removed by catheter contained some albumin and casts and was extremely acid in reaction. (No test was made for the acetone bodies.) In spite of the odor of the anesthetic this boy's breath had the peculiar sweetish rotten-apple odor characteristic of acetonemia. His condition went from bad to worse and at the end of eighteen hours he died. At the time I did not recognize the nature of the trouble.

Case 2.—A year later a second case of the kind occurred. The patient, a nervous, so-called hysteric girl, aged 18, whose history showed that she had suffered much from vertigo and from persistent neuralgic headaches and from an irritable bladder, had also had an interval appendectomy. She had often had vomiting spells and had been told that she was a victim of the uric acid diathesis. She was constipated, but suffered from frequent attacks of diarrhea. The urine before the operation did not contain albumin or sugar, but was very acid.

The anesthetic in this case was ether and a large amount had to be administered because of the difficulty in keeping the patient relaxed. She left the table with a rapid, thready pulse, persistent vomiting and dyspnea. In a few hours her temperature had reached 104 by rectum. The urine was heavily charged with acetone, and the odor could be easily detected on the breath. The urine also contained albumin and casts. She died in twelve hours.

Case 3.—A woman aged 24, with a history of chronic colitis and periods of obstinate constipation, with tenderness and gurgling in the right inguinal region, had been advised a year before to undergo operation for chronic appendicitis. Two weeks before the operation she consulted her family physician for relief from persistent headache, general muscular soreness, mental depression and occasional fainting spells. At the time the tongue was coated, the breath bad and the urine extremely acid and containing indican. Nitrous oxid and oxygen was the anesthetic and no ether at all was given. Once the anesthetic had to be withdrawn because of the danger of respiratory failure, and she never was completely relaxed. She failed to completely regain consciousness, and developed persistent vomiting, an intermittent, irregular and rapid pulse, marked dyspnea and a rapid rise in temperature to 105 in less than five hours after the operation. The breath was characteristic and unmistakable, and the urine, which was secreted at the rate of about 2 ounces per hour, was heavily charged with acetone, but no albumin or casts, and the specific gravity was low. She was given alkalies by the bowel and in a vein, but without avail. Death occurred in about twenty hours.

Case 4.—Mrs. ———, aged 38, above the average height, the sister of a well-known physician, sought relief for a large uterine fibroid which for about a year had caused a considerable loss of blood and much pain. For a number of weeks she had lived on an almost carbohydrate-free diet, a part of the time living on meat extract broths. During this time she had developed a chain of very distressing nervous symptoms, most prominent of which were vertigo attacks, great excitability, with a pronounced muscular tremor on slight exertion, and frequent headaches, with occasional attacks of persistent vomiting lasting as much as twenty-four hours. I saw her first in the afternoon preceding the day set for the operation, and on entering the room was immediately struck with the pronounced odor of acetone. The patient was propped up on pillows, saying that she could not get her breath easily when lying down. The pulse was rapid and she was much excited. She said that she had not slept any on account of nervousness for three nights and felt a firm conviction that she would die. The urine examination showed an enormous amount of acetone, but no albumin or sugar. Operation was deferred, and the patient, under the care of Drs. D. M. Stone and B. F. Stout, was kept for a week on a diet of 6 ounces of oatmeal with milk, sugar and cream daily. She was made to drink large quantities of carbonated water, and had colon irrigations twice daily with an ounce to the quart of sodium bicarbonate and from 3 to 5 drams daily of sodium citrate by mouth. On the morning of the fourth day the patient stated that she had had her first restful night's sleep in six months, that her headaches and nervousness had entirely disappeared, and that she did not dread the operation any longer. She was now quite cheerful. The change in her condition was indeed remarkable. The pinched, anxious, haggard expression had disappeared and she seemed quiet and relaxed and rested. On this day there was but a trace of acetone, and the urine was alkaline in reaction. Three days later she was operated on, her pulse having been reduced in the meantime from 120 to 78 when at rest. Ether was given. She left the table in good condition, but at the end of six hours became restless, and began to vomit and to suffer from dyspnea. The urine again contained acetone and some albumin, with a few granular casts. The stomach was washed out with a strong sodium bicarbonate solution and she was placed on the Murphy drop with sodium bicarbonate solution, an ounce to a quart. In a few hours her condition was again normal. She made a good recovery, but three months later called at my office complaining again of headaches and nervousness, and confessed that she had failed to follow directions with reference to diet, etc. The alkalies, diet, warm bathing and. alkaline irrigation soon restored her to normal.

CASE 5.—Miss E., a trained nurse, aged 26, gave a history of having had appendicitis when a child and having suffered from obstinate constipation, a coated tongue and flatulency and headaches ever since. During the past year she had had a number of attacks of intestinal colic, always accompanied with nausea and vomiting and great nervousness. Recently she had had several severe attacks of pain in the right side with rigidity, vomiting, extreme prostration and a fear of impending death. This girl had always been unwise in the selection of her diet. She drank very little water and her diet consisted chiefly of proteins. The urine contained indican and acetone and was very acid. She was prepared for the operation with a view to eliminating the danger of acetonemia and stood the operation well, except that she resisted the anesthetic very much and could not be relaxed. In spite of our efforts she had four days and nights of intense suffering from pain, restlessness, vomiting dyspnea, headache and abdominal distention. The ascending colon had been stripped of a very extensive pericolic veil, but this could not account for the pain and distention. She finally recovered after a rather tedious convalescence, during which colon irrigations with a soda solution played a prominent part in the treatment.

I have collected the records of thirty-four cases, in which a fatal issue resulted in seven. The cases reported, however, are typical and I will not lengthen the paper by detailed reference to the others.

CONCLUSIONS

Because of a marked reduction in the normal alkalinity of the blood, the result of some perversion of metabolism, many of the patients requiring surgical operations are unfit subjects for general anesthesia and the ordeal of an operation. The warning signs in such cases are:

1. A history of unaccountable headaches, vertigo, attacks of dyspnea, occasional nausea or vomiting, an unreasonable dread of the operation, tachycardia and other nervous symptoms.

2. A peculiar sweetish odor to the breath, suggesting the odor of rotten apples. In some cases this is marked and unmistakable.

3. The presence in the urine of the acetone bodies.

To disregard these warning signs is to subject the patient at best to (1) an anesthesia requiring large amounts of ether or chloroform, and attended with struggling and great rigidity of the muscles, difficult breathing, a rapid pulse and nausea, followed by a prolonged and nerve-racking convalescence with persistent vomiting, restlessness, dyspnea, a rise in temperature and much suffering, or, if less fortunate, to (2) the certainty of a fatal termination, preceded by nausea, air-hunger, persistent vomiting, a rise in temperature, great nervousness, followed by coma and death in from ten hours to two or three days.

A recognition of acidosis in time followed by the institution of such measures as a carbohydrate diet of, say, from 6 to 8 ounces of oatmeal and cream with lactose, large quantities of carbonated alkaline water, colon flushings with an alkaline solution and the internal administration daily of 3 or 4 drams of sodium bicarbonate or sodium citrate by mouth will be followed by a rapid disappearance of all or most of the unfavorable symptoms, and the patient will be rendered for the time being at least a safe subject for the anesthetic and the operation.

Hicks Building.

VON MIKULICZ' DISEASE—FURTHER STUDIES

WILLIAM LINTZ, M.D.
Associate Visiting Physician at Brooklyn Jewish and Kings County Hospitals
BROOKLYN

Von Mikulicz' disease is a chronic, indolent, symmetric enlargement of one or more of the salivary or lacrimal glands, which is non-painful and which von Mikulicz could not classify under any of the diseases heretofore described. The first case of this nature was presented by von Mikulicz,[1] Jan. 23, 1888, before the Verein für wissenshaftliche Heilkunde at Königsberg. In 1894 von Mikulicz first described what he thought was a distinct and typical well-defined heretofore undescribed disease.

The following case is an example of his syndrome:

History.—M. B., a man, aged 22, feeder by occupation, was born in the United States of parents from Galicia, Austria, who have been married for thirty years and have ten children, all living and well with the exception of one who died from an infectious disease in childhood. Both parents are alive and enjoy perfect health. The patient, whom I saw March 4, 1912, does not drink or smoke; he is very nervous and consumes a great deal of coffee. At the age of 2 he became blind and remained so until 7 or 8 years old. Vision is poor now. At the age of 3 he had infected cervical lymph-nodes, which were lanced. He has always been troubled with nasal catarrh and cannot breathe through the nose. For the last four years he has been having a hemorrhage [from lung (?)] once a year. He has stomach trouble and is constipated. About five years ago he had skin disease associated with constant itching. For the last six years he has been ruptured. He has had discharge from the left ear for years. The patient had a soft chancre four years ago which healed without treatment; he has not taken any internal treatment; he never had gonorrhea. Three years ago he noticed a painless swelling appear over the right submaxillary region. About two years later the left submaxillary and the right parotid glands became enlarged.

---

[1] Von Mikulicz: Berl. klin. Wchnschr., 1888.

These swellings are absolutely painless and fluctuate in size, becoming larger and then smaller at times, apparently without any cause. The patient has dryness of mouth, and coughs and expectorates slightly. He feels perfectly well otherwise.

Examination.—Swellings: Both submaxillary glands are smooth, symmetrically enlarged to the size of a hen's egg, are freely movable and the skin over the glands is also freely movable. Right parotid gland enlarged to the size of a hen's egg and has the same characteristics as the submaxillaries. The swellings are firm in consistency, not tender, and show no evidence of inflammation or fluctuation. The remaining salivary, as well as lacrimal glands, are perfectly normal.

General: Patient is well built and nourished, and the mucous membranes are not pale. Posterior cervical, epitrochlear, axillary and inguinal lymph-nodes are palpable. Six scars on the neck mark the location of the before-mentioned operation. The thyroid gland on the left side is somewhat enlarged, and is smooth, soft and homogeneous. The tibia is irregular in outline and contains pigmented scars. There is also a pigmented scar over the left patella.

Mouth, Nose and Ears: Patient breathes through the mouth; cannot breathe through nose. Tongue is coated and dry; tonsils enlarged and throat is red and congested. He has a very narrow and high-arched palate. There is more breathing-space in the right nasal cavity than on the left side. He has adenoids and hypertrophied turbinates, is hard of hearing, and the left ear is discharging.

Heart: Negative.

Lungs: Dulness of right and left apices. Occasional subcrepitant râle and roughened breathing over left apex.

Abdomen: Liver and spleen not enlarged. No masses palpable and no resistance can be felt.

The temperature, pulse and respirations are practically normal.

Treatment and Course.—Dietetic and hygienic measures were adopted, with Fowler's solution and potassium iodid. May 5, 1912, the patient suddenly began to have hemorrhages from the lung, altogether twenty-four in number. He went to Denver, stayed two weeks and then went to Omaha, where he stayed one week and returned to New York. He was rapidly failing, when at this time he was advised by an old woman whose husband had had what had been pronounced as fatal tuberculosis and had cured himself by drinking his own urine. Patient has been drinking daily, since Aug. 15, 1912, from three to five glasses of urine, immediately after voiding. At first he used to have abdominal cramps after drinking urine, but now he feels no pain and in fact likes the beverage. Since he began this treatment the patient has felt very much improved. Not only have the salivary glandular swellings diminished in size or returned completely to normal, but his general health has greatly improved. He looks very much better and has gained in weight. His appetite has improved, he has lost his night sweats, and coughs considerably less. His hearing has improved, although his ears discharge just as much as previously. The nasal discharge is considerably less. Tubercle bacilli are present in the sputum.

April 6, 1913: The parotid glands on both sides are normal; no swelling can be felt on the right side. The submaxillary glands on the left side are the size of a hazelnut. On the right side the gland is divided into two parts, is round, smooth and movable, and the skin over it is movable; one is the size of a hazelnut, the other the size of a pea. The lacrimal glands are not involved.

General: The patient still breathes through the mouth; he cannot breathe through the nose. The tongue is coated with grayish-white fur: the tonsils are red and hypertrophied. There is a grayish-green membrane on the posterior pharynx. The lymph-nodes are palpable.

Chest: The supraclavicular and infraclavicular fossa are deeper on the left side. The left clavicle is more prominent. There is dulness over the right apex and left upper lung. There is prolonged and roughened expiration over the right apex. Roughened breathing and subcrepitant and crepitant râles are present in the left upper lobe of the lung.

The abdominal organs are negative. The weight of the patient is 125 pounds.

BLOOD EXAMINATION

	March 4, 1912.	April 4, 1913.
White blood-cells, total..	....	21,500
Polymorphonuclears	80 per cent.	76 per cent.
Eosinophils	0 per cent.	1 per cent.
Lymphocytes (small).....	18 per cent.	21 per cent.
Mononuclears	1.5 per cent.	....
Mononuclears and transitionals	....	1.5 per cent.
Mast-cells	0.5 per cent.	0.5 per cent.
Red cells, total.........	....	9,100,000
Anisocytosis	none.	none.
Poikilocytosis	none.	none.
Polychromatophilia	none.	none.

Urine Examinations: Repeated urine examinations yielded but negative results. The cytology as well as the bacteriology was negative. Repeated examinations for tubercle bacilli proved negative.

Examination of Saliva: Appearance, cloudy; sediment, moderate; reaction, alkaline to litmus; albumin, none; potassium sulphocyanid, none; chlorids, present; nitrates, present; carbonates, none; ferments: all tests showed that the saliva was capable of changing starch into sugar. Microscopic: Numerous bacilli, spirilla and cocci, squamous epithelium, débris, and starch granules.

Wassermann reaction of blood, negative.

CONSIDERATION OF VON MIKULICZ' DISEASE

Location.—In von Mikulicz' classical case not only were all the salivary glands involved but also both of the lacrimals. In January, 1911, I[2] presented before the Brooklyn Pathological Society, a case of von Mikulicz' disease in which only both parotids were involved. Similar cases were reported by Lafolley,[3] Battle,[4] Kummel,[5] Quincke,[6] von Reuss,[7] Minelli[8] and Apert.[9] Involvement of the submaxillaries alone were reported by Kummel, while that of the sublingual alone has occurred but once (Reinbach[10]). Involvement of one of the pair of glands has been reported in the parotid by Kuttner[11] and in the lacrimal by Berlin[12] and Coppez.[13]

Pathology.—Pathologically these cases differ a great deal. In general the lesions may be divided into two classes. In one type of cases the chronic inflammatory changes are conspicuous; in the other type the lymphadenoid hyperplasia.

The majority of writers have found a diffuse round-cell or lymphocytic infiltration, and isolated collections of lymph-nodules embedded in the parotid gland. These nodules are circumscribed and resemble lymph-follicles and are irregularly distributed in the tumor. There is abundant vascular supply, the walls of which show a distinct thickening and sometimes hyaline and amyloid degeneration (Kirschbaumer[14] and Reymond[15]). The capillaries may show a proliferation of the interstitial and connective tissue with resulting sclerosis (Zinn, Kirschbaumer[14] and Swegireff[16]). The gland proper plays a passive rôle, undergoing secondary atrophy and degeneration as a result of compression, until it may completely disappear (von Mikulicz, Minelli,[8] and Swegireff[16]). These authors believe that the process originates in the connective tissue and that the gland element plays a passive rôle. Hirsch,[17] Haeckel,[18] Kuttner[11] and a few others believe that the process originates in the epithelium of the gland proper, which undergoes primary degeneration as a result of the action of some toxic agent, which perhaps reaches the epithelium through the duct of the gland, resulting in a secondary proliferation of the connective tissue. Hirsch[17] has observed independent degeneration of the gland parenchyma in all stages of the disease, affecting even the lobules which were not related to the round-cell infiltration. Haeckel[18] saw in some cases a transition of masses of round cells into connective tissue. A beginning degeneration of the gland epithelium occurred when the gland seemed otherwise normal and free from round-cell infiltration and new connective tissue.

A certain number of so-called "leukemic cases" have been reported; here the usual pathologic anatomic picture is presented, namely, a nodular or diffuse formation of atypical lymphoid tissue. Warthin asserts that so far as the essential pathology is concerned no histologic difference can be discovered between the two types (leukemic and aleukemic), and that one may pass into the other.

Giant-cells, eosinophils and few epithelial cells have been found in my case previously described, as well as by Tietze,[19] Kummel[5] (Case 25), Stowar,[20] Baas,[21] Minelli,[8] Napp,[22] Kulbs[23] and others.

General.—This disease affects both sexes alike and occurs between the ages of 4 and 70. The duration of an attack varies from two months to twelve years and upward. Xerostoma is, as a rule, a prominent symptom, and it may seriously interfere with mastication or deglutition, depending on the degree of devolvement of the salivary glands. In some cases not only are the salivary glands mentioned before involved, but also the secondary salivary glands of the hard palate, and under surface of the tip of the tongue (Blandin-Nuhn glands) and of the lateral aspect of the posterior portion of the tongue (Weber's glands), are affected. When there is involvement of the lacrimal glands there is ptosis and exophthalmos with hardly any mechanical interference with vision. Lacrimation is usually only an early symptom. The process may be reversed involving first the lacrimal and then the salivary glands, or it may involve one without involving the other, or involve but one gland or any combination of glands. There is none or but slight enlargement of the lymph-nodes. The spleen is not enlarged. Hypertrophied tonsils and adenoids infrequently occur. In most of the cases the blood-picture as a rule is normal. Yet quite a good many authors report cases in which involvement of the hemopoietic system did occur, developing ultimately in typical cases of leukemia and pseudoleukemia (Stock,[24] Senator,[25] Marcuse,[26] Osler,[27] Dunn,[28] Cutler,[29] Gallasch[30] and Bock[31]). The tumors may temporarily or even permanently subside during the course of an acute infection such as general peritonitis, pneumonia, erysipelas, acute pleurisy with effusion and cholera (von Mikulicz, Kummel,[5] Quincke[6] and Zirm, Osler and Delens). After complete extirpation of the involved glands there is invariably no tendency toward recurrence. My first patient is perfectly well to-day, three years after operation. The course of the disease is excedingly chronic, and not infrequently a complete cure may be obtained spontaneously or by therapeutic measures. Of especial value in this disease are arsenic, mercury, iodids and the Roentgen ray. Of itself the disease is not fatal and has no tendency to shorten life.

Pathogenesis and Etiology.—There is no uniform agreement as to how and what is the cause of the disease. Most men believe that the disease is caused by an infection from the buccal or conjunctival bacteria or some parasitic process in the widest sense of the term, though no specific bacteria have been demonstrated in these cases. The infection, when it arises from the conjunctiva, passes thence to the lacrimal gland and by the lacrimal duct to the buccal mucous membrane and the salivary glands, owing to the proximity of both in the nasopharynx. In many cases there was a preexisting disease of the conjunctival mucous membrane (Becker, von Mikulicz, Adler,[32] Haltenhoff[33] and my[2] first case). This patient gives a history of blindness at the age of 3 which lasted for three or four years. Kummel[6] considers that the first conjunctival and second salivary groups of cases depend on the different entrance points.

Ziegler[34] believes that the condition is due to toxic fluids that are chemically irritating, which are probably absorbed from the accessory sinuses (chiefly antrum) and transmitted through the lymphatic capillaries to these contiguous glands. This patient has nasal catarrh and respiratory obstruction.

Apert[9] believes that the condition is caused by hypothyroidism. Some believe that the disease is caused by glandular irritation from some toxic agent in the blood or lymph-stream, causing lymphatic hyperplasia. Others believe that it is of idiopathic origin. Berlin,[12] Arnold, Minelli,[8] Tietze[19] and others compare the process to hypertrophy of the tonsils and adenoids, the hypertrophy taking place from preformed lymphatic tissue in the orbits, between the gland alveoli and capillaries of salivary and lacrimal glands. Wallenfang thinks that it is a pseudoleukemic condition. Minelli believes that it is a benign lymphoma of the salivary glands, which may become generalized just as is the case in Hodgkin's disease.

SUMMARY

After a careful review of all the cases in the literature, I stated, in the description of my first case, that "lues, tuberculosis, or both, in their latent or active stages play an important rôle in this condition, and that the variable pathologic picture is directly dependent as to which one is present or predominates." The present case only corroborates this view. And to my mind it is exceedingly doubtful if von Mikulicz' disease should be classified as a complete and separate entity.

The Wisdom of Doubt.—It will be well for us to remember the words of Pasteur: "In experimental science it is always a mistake not to doubt when facts do not compel you to affirm."—F. M. Sandwith, in (London) *Clinical Journal.*

GAS BACILLUS INFECTION—A REPORT OF SIX CASES *

L. BRUCE ROBERTSON, B.A., M.B.
BOSTON

There has recently appeared in the *Annals of Surgery*[1] a comprehensive report by Dr. Cramp of this hospital on this type of infection, therefore, it will be unnecessary to go into detail in regard to the history of the cases previously reported. Of the two deaths in this series, one was caused by a deep infection of the thigh muscles complicated by considerable hemorrhage; the other was that of a patient admitted in an advanced stage, though the infection was controlled before the patient succumbed to a pulmonary disease.

That an infection of this type in a localized area can be overcome by the body tissues, as in the untreated interscapular area in Case 2, is a fact already proved by Blake and Lahey.[2] The hydrogen peroxid used in these cases was the undiluted U. S. P. 3 per cent. solution.

CASE 1.—W. D., aged 17, was admitted June 18, 1912, to the service of Dr. L. W. Hotchkiss. June 17, the patient fell from a height of five stories sustaining a compound fracture of the right tibia and fracture of the fibula. The wound was dressed and splints applied at another hospital and the patient was transferred to Bellevue the next day.

June 18: Temperature was 103; pulse 132; respirations 28. Physical examination was negative except for a compound fracture of the right tibia about 5 inches above the ankle; the fibula was fractured at about the same level. The wound was dressed with 7.5 per cent. solution of tincture of iodin and splints applied.

June 20: Temperature still elevated to about 103. Interstitial crepitus has become evident about the wound and extends upward toward the knee; leg very painful. Under nitrous oxid anesthesia, free longitudinal incisions were made in the crepitant tissue, gas bubbles of characteristic odor and dark red fluid exuding from the wounds. A thorough hydrogen peroxid irrigation was made and a dressing of peroxid-soaked gauze was applied. Both smear and culture from the fluid showed the *Bacillus aerogenes capsulatus.*

For the next two weeks the temperature fluctuated between 101 and 105 daily, and the patient had chills almost every day. Complete dressing was made but once a day, being so painful that on each occasion nitrous oxid had to be administered. Throughout the day the dressings were kept moist with peroxid. There was no extension of crepitus following the primary operation, and the wounds, though sloughy, and at first, giving off a disagreeable odor, gradually became clean and healed by granulation. There was severe persistent pain which at times could be relieved only by morphin.

The progress of the patient, except for a small superficial abscess on the back, which yielded quickly to treatment, was very good, and on August 18 the wounds were sufficiently healed to permit the leg to be encased in a plaster splint in which a window was cut to allow a discharging sinus to be dressed. On September 12 a painless swelling appeared in the lumbar region which when opened contained clear fluid showing, on culture, colon bacillus infection. On September 15 a small sequestrum was removed from the discharging sinus on the leg. By this time the temperature of the patient had become normal. Radiographic examination on October 1 showed osteomyelitis of the tibia about the seat of fracture with the presence of a sequestrum, but further operation at this time was considered inadvisable. Three weeks later, the patient, at his own request was discharged in care of his relatives for further treatment in the country. A report of this case made some five months later by Dr. E. M. Armstrong of Tuxedo, New York, shows a small sinus leading down to the bone and incomplete union at the site of the fracture.

CASE 2.—J. S., aged 29, admitted July 1, 1912, to another division of this hospital, had sustained, about half an hour prior to admission, a compound fracture in the upper third of the left humerus, caused by a blow from a paving-stone thrown from a height of five stories, the force of the blow felling him. On admission the wound was swabbed out with 7.5 per cent. solution tincture iodin and dressed with gauze soaked in 50 per cent. alcohol and splints were applied. Pulse in left wrist palpable. Temperature 97; pulse 65; respirations 20.

July 3: Temperature rose steadily yesterday afternoon, rising to 102.4 to-day; pulse 130, respirations 34. Interstitial crepitus found to be present about wound in arm and spreading across to midline anteriorly.

The operation under ether anesthesia in another surgical division of this hospital was a free incision in the deltoid as well as below the seat of fracture and in the anterior axillary fold. All incisions were connected and irrigated with hydrogen peroxid; drainage was by rubber tubing, the dressing of peroxid-soaked gauze. A thin dark red fluid containing gas bubbles which was obtained from the wounds showed the presence of the *B. aerogenes capsulatus.*

The case was transferred to the service of Dr. Hooker.[3] By 10 p. m., the same day the condition had become progressively worse, the patient being very weak and toxic. The interstitial emphysema extended across the breast to the right axilla and upward over the right clavicle to the supraclavicular fossa. In the neck the crepitus extended across the midline anteriorly and upward on each side to the level of the thyroid cartilage, and within 2 inches of the midline posteriorly; the lower limit of the crepitus was found in the fifth interspace at the sternum. The left wrist was pulseless. Under a general anesthetic very free incisions were made in the right breast and on each side of the neck, and blunt dissection was carried out widely through the crepitant tissue. Thorough peroxid irrigation and dressing of peroxid-soaked gauze was made. Dressings were changed every three hours and kept moist with peroxid.

July 4: Temperature 99.8; pulse 120; respirations 26. Patient weak and apprehensive; profuse sweating. No extension of crepitus beyond limits noted yesterday except a small isolated patch about 3 cm. in diameter high up between the scapulae. *This was not opened.* The left arm below the fracture was pulseless and becoming gangrenous.

July 6: Temperature 100; pulse 104; respirations 26. General condition improving slowly though patient shows signs of absorption from the gangrenous arm, in which the line of demarcation is forming. Interstitial crepitus is subsiding; the interscapular area has practically subsided without being opened.

July 8: The general condition is improving. Amputation of the left arm was done at the line of demarcation; the stump was left open and packed with peroxid-soaked gauze. The condition in neck and breast is improving.

The subsequent progress was very good; a localized furunculosis developed over the sacrum, but responded readily to incision and drainage. Except for a slight pocketing of pus in one of the wounds, those of the body and neck healed well by granulation. On July 12 some sloughs from the amputation stump still showed the presence of *B. aerogenes capsulatus* in spite of constant dressing with peroxid. The patient improved steadily, and on August 8, under ether anesthesia, the upper end of the left humerus was removed by incision through the joint capsule; the stump was left open and packed with gauze. The excised head of the humerus showed areas of necrosis. The patient was discharged from the hospital August 21 and by September 14 the stump was healed by firm scar tissue.

CASE 3.—S. J., aged 35, was admitted July 21, 1912, to the service of Dr. R. S. Hooker. Was wounded in the middle of the left thigh by the charge from a shotgun fired from a distance of 12 feet while he was attempting to rob a barge.

[2] Blake, John Bapst, and Lahey, Frank H.: Infections Due to the Bacillus Aerogenes Capsulatus, THE JOURNAL A. M. A., May 21, 1910, p. 1671.

[3] Presented by Dr. R. S. Hooker, at the meeting of the Society of Clinical Surgery in New York, November, 1912.

Temperature was 99.4; pulse 84; respirations 26. The injury occurred about one hour prior to admission to the hospital. On the anterior aspect of the left thigh was a large irregular wound in which the entire hand could be inserted and which extended backward past the inner side of the femur. The femoral artery could be felt pulsating in the posterior part of the cavity. Several gun wads and numerous leaden pellets were picked from about the artery and out of the depths of the wound. The cavity was irrigated with peroxid and swabbed out with 7.5 per cent. solution of tincture iodin. There was profuse oozing, and the wound was packed with lengths of gauze. Repacking was necessary in the afternoon on account of the persistent oozing. The severe pain in the leg was controlled by morphin. At 9 p. m. the temperature was 102.8; pulse 116; respirations 24.

The following day the temperature rose to 104 and the patient complained of pain in the affected leg. The outer packing was changed on account of a recurrence of the oozing. Tetanus antitoxin, 1,500 units, was administered.

The next day the patient became rather restless and complained of great pain in the leg. Temperature 103.2. There was a dark reddish fluid on the outer dressing and a disagreeable odor from the leg. No interstitial crepitus was felt. A diagnosis of gas bacillus infection was made, the thigh was opened up widely, irrigated with hydrogen peroxid and dressed with peroxid-soaked gauze. At operation the intermuscular planes were found to be infiltrated with a dark red fluid and gas bubbles giving the characteristic odor. Death occurred thirty hours later.

CASE 4.—M. W., a woman, aged 46, a prisoner, was admitted to the service of Dr. R. S. Hooker, July 21, 1912, having suffered a fracture dislocation of the upper end of the right humerus and a Colles' fracture of the right wrist. Temperature was 99; pulse 100; respirations 24. The body was filthy and showed multiple contusions; the legs were discolored and ulcerated. The patient was put in bed under restraint. The general condition was poor and the patient incontinent. The fractures were treated by plaster splints.

July 26: Temperature was 101.6; pulse 110; respirations 24. A large superficial bleb has appeared over the dorsolateral aspect of the first metacarpophalangeal joint of the right foot, the upper half of the bleb being occupied by a single large gas bubble. On incision the fluid below the bleb was found of a dirty, grayish-green color and the gas had a foul, disagreeable odor. The fluid was positive for *B. aerogenes capsulatus*. The base of the bleb was composed of sloughy superficial fascia. No interstitial crepitus was present in the foot. The affected area was irrigated with hydrogen peroxid and dressed with peroxid-soaked gauze.

Further progress was uneventful. The temperature came down to normal three days later, and for the next twelve days rose to about 99 each day. By August 15 healthy granulations were present over the affected area and the patient was discharged to court.

CASE 5.—W. S., a Russian man, aged 55, was admitted July 24, 1912, to another division of this hospital. Temperature was 103; pulse 100; respirations 29. Three days prior to admission a soft rubber catheter had been passed into the bladder, and for the last twenty-four hours patient had had some trouble in voiding urine. The history was unsatisfactory and indefinite. The patient had complained of no lesion about the anus. Scrotal swelling had appeared within the previous forty-eight hours. Patient was well nourished and well developed, but appeared very toxic. The lungs showed dulness and fine crepitations at both bases posteriorly and bubbling râles were heard throughout them. The heart sounds were of only fair quality.

Local Condition.—The scrotum was about four times its natural size, red, shiny and rather tense. The swelling was elastic and fine interstitial crepitus could be felt throughout the scrotal tissues. No fluctuation was present. There was an erythematous, indurated area with well-marked and slightly raised border extending out toward the ischial tuberosities on each side of the anus, forward on the perineum and upward on the pubes, and for a short distance on the inner side of each thigh. Catheter No. 20 F could be introduced into bladder without difficulty.

The operation was twelve hours after admission in another surgical division of this hospital and consisted of a free anteroposterior incision in the scrotum on each side of the median raphé, with a free median perineal incision. The scrotal tissues were found to be infiltrated with small gas bubbles and a dark reddish fluid of a disagreeable and characteristic odor. *B. aerogenes capsulatus* was found in smear and culture. Blunt dissection into the crepitant tissue was performed with hydrogen peroxid irrigation and the wounds were lightly packed with peroxid-soaked gauze. The patient was transferred to the service of Dr. R. S. Hooker. Some hours later, owing to the extension of the crepitus upward to each inguinal region and backwards over each ischial tuberosity, incisions were made in those regions and connected with the scrotal and perineal wounds, respectively, by undermining the intervening skin. Irrigation with peroxid and packing with peroxid-soaked gauze were repeated.

During the next five days the temperature was normal, the dressings were changed frequently and kept moist with peroxid. Although there was some sloughing of the scrotal tissue between the two lateral incisions, the induration decreased and there was almost complete subsidence of the gas bacillus infection. The edema of the lungs increased steadily, with only one period of temporary improvement, and the patient died five and one-half days after admission.

CASE 6.—W. R., an Italian boy, aged 5½, was admitted Dec. 15, 1912, at 6:30 p. m., to the service of Dr. John B. Walker. The patient was in shock suffering from a fracture in the upper third of the left femur, and a severe crushing, without open laceration of the left leg below the knee. The right thigh showed a compound supracondylar fracture of the femur and extensive crushing and laceration of the right leg below the knee. The patient had been run over by a wagon. The wounds were irrigated with a diluted aqueous solution of tincture of iodin; dressings and splints were applied and efforts made to counteract the shock. Temperature was 98; pulse 162; respirations 42.

December 16: The patient was very restless and fretful; some bloody discharge was on the dressings. At 8 a. m. temperature was 98; pulse 152; respirations 40. At 8 p. m. temperature was 102; pulse 162; respirations 42.

December 17: Temperature 104; pulse 164; respirations 42. When the dressings were removed a thin, reddish fluid with a disagreeable odor came from the lacerated wounds on the right leg. No interstitial crepitus could be felt. No circulation was present below the right knee. With a commencing gangrene of the leg and the strong probability of gas bacillus infection it was thought advisable to amputate above the supracondylar fracture in the right femur. This was done and smears taken, not only from the lacerated tissues, but also from the cut muscular surface of the amputated leg. Both showed the presence of *B. aerogenes capsulatus*, though examination afterward of the amputated leg showed gas bubbles only in the deeper calf muscles. No reddish fluid or gas bubbles were present at the site of amputation. On account of the presence of the gas infection at the amputation site the stump flaps were opened up and packed with peroxid-soaked gauze.

December 18: interstitial crepitus was found in the stump. The affected areas were opened and irrigated with peroxid. Temperature was 103; pulse 150; respirations 28. The patient was delirious at the time and very weak.

December 19: There was an extension of interstitial crepitus in the stump, a free incision under nitrous oxid anesthesia was made, and peroxid irrigation used. By December 25 all interstitial crepitus had disappeared and healthy granulations were appearing. The left leg showed dry gangrene below the knee. The patient's general condition had improved, though he was much emaciated. Two weeks later amputation at the middle of the left thigh was performed for deep infection of the left leg which had developed in the dry gangrene and had spread to the knee. From this time on the patient improved steadily and by Feb. 2, 1913, the afternoon temperature reached only 100. The left stump healed by primary union and the right stump by healthy granulations about the protruding end of the cut femur, which shortly afterward was removed under ether anesthesia, the wound healing by granulation. The patient was discharged for further treatment in the country. When seen last on March 23, 1913, there was a small area of healthy granulations on the right stump and the general condition was excellent. For permission to report the cases, I am indebted to Drs. Hotchkiss, Walker and Hooker, of this hospital, and further to Dr. Hooker, for his kind assistance in the preparation of these notes.

A CASE OF TUMOR OF THE HYPOPHYSIS

PARTIALLY REMOVED BY THE TRANSFRONTAL METHOD OF APPROACH

CHARLES HARRISON FRAZIER, M.D.
AND
JAMES HENDRIE LLOYD, M.D.
PHILADELPHIA

MEDICAL NOTES BY DR. LLOYD

The following case occurred recently in my wards at the Philadelphia General Hospital. As a hypophyseal case it is noteworthy for two things, namely, the presence of marked pressure or "neighborhood" symptoms, and the absence of a distinct cachexia either of acromegaly or of the dystrophia adiposogenitalis. The patient was neither infantile nor acromegalic; he was not overgrown or undergrown; he was neither too fat nor too lean; neither too large nor too small; his sexual organs were normally developed and he did not have a "hypotrichosis" either of his face or of his pubes; he had no craving for sweets, nor had he any diabetes or polyuria, and his temperature range was normal. What he did have was rapid onset of blindness with headache and vomiting, and he presented, under the Roentgen ray, the evidence of a pituitary tumor. In addition to headache he had at various times, as will be seen in the clinical report, severe pains in the limbs (and even in the chest); and to these pains, as an unusual feature, we invite special attention. Somewhat similar pains have been reported in acromegalia; thus Cushing, in one of his cases, describes pains in the limbs, in the active period of overgrowth, as somewhat like growing pains. Whether such pains may really be referred pains, caused by pressure on or irritation of the cerebral peduncles, is a subject worthy of consideration. In this connection it may be well to recall the fact that referred pains are sometimes observed in lesions in other basal structures, as for instance in the optic thalamus. Pain in the paralyzed limbs has also been observed in hemiplegia even before the attack. In the partial obscurity which still shrouds the course of the pain fibers, it is impossible to do more than to theorize about the relation of these clinical facts with the facts of anatomy, but to me it is conceivable that a pituitary lesion might, by pressure, as by a hydrocephalus, cause involvement of these pain-tracts as they pass cephalad. Their course is doubtless through the cerebral peduncles and the optic thalami.

Patient S. W.—Russian, aged 21, was admitted Aug. 27, 1912. Family history was negative. The patient came to the United States from Russia in 1911. He is a fairly well-developed young man. He used alcohol and tobacco moderately and denies venereal infection. He had always been in good health up to the onset of his present illness.

Present Illness.—This began in August, 1911, when the patient was suddenly seized with violent headache, more marked on the right side, and repeated vomiting spells. The vomiting was propulsive, not preceded by nausea, except sometimes for a few moments, and occurred irrespective of eating, as a rule. This headache with vomiting lasted for several weeks and then ceased rather suddenly. After this illness the patient noticed that his vision was becoming hazy and that he saw double. He then began to have shooting pains in his right shoulder and arm, attended with tremor and convulsive movements of this limb. These movements do not seem to have been epileptic. At this time he received glasses at the Wills Eye Hospital, where a diagnosis was made of chorioiditis of the macular region. In June, 1912, the patient had another attack of headache and vomiting, not so severe as the former. After this second attack his vision failed still more until, on admission to the Philadelphia General Hospital, he could see only a little out of his left eye, and at best could only tell the difference between light and darkness. He said, also, that he had had a staggering gait since his first attack of headache.

Examination.—The patient was seen to be a fairly well-nourished young Hebrew. His musculature was rather poorly developed, but there was no excessive adiposis. His sexual organs were well developed and he had hair on his face and pubes. His gait was steady, without swaying or staggering, although somewhat uncertain because of his blindness. He was not paralyzed in any of his muscles. The knee-jerks were normal; Babinski reflexes absent; skin reflexes normal; sphincters not involved. The patient's mentality was good. The eyes were examined by Dr. Shumway, who made the following report: Double optic nerve atrophy probably following optic neuritis. The edges of the nerve-heads were obscure; the arteries very narrow; veins of good caliber. The nerve-heads were filled in from inflammatory changes. The eyes were entirely sightless and there was no pupillary response. The ocular movements were well performed; the eyeballs, at rest, slightly divergent.

After admission to the hospital the patient had a great deal of headache, coming and going, with attacks of cerebral vomiting. These attacks, and his blindness, constituted practically the whole of the symptomatology for a long while. The patient preferably remained in bed, lying on his back, often holding his hand to his head; but he had free use of his limbs and could arise and walk if requested. His mental state continued good and he had no speech defects. It is especially noteworthy that he occasionally complained of pains in his legs; these pains, taken in conjunction with similar pains which he had had in his arms before entering the hospital, and with the severe pains which he had in his arms and chest after the operation, as will be seen, may have more than usual significance. The patient never had an epileptic attack, nor any uncinate or olfactory aurae.

On one occasion the patient had pain in his right ear and under his right eye, followed by a slight chill and a little discharge from the ear. There was no tenderness or redness over the mastoid, but slight tenderness in front of the tragus. The attack passed by under the care of Dr. Grayson.

The heart, lungs and kidneys were normal. There was no polyuria.

The patient did not present the appearance either of acromegaly or of dystrophia adiposogenitalis.

The examination of the blood and cerebrospinal fluid gave the following result: The Wassermann test was negative in both. The cerebrospinal fluid was negative to the Nonne and Noguchi tests; no lymphocytosis.

The roentgenogram revealed the following condition: The floor of the sella turcica was entirely destroyed. A portion of the posterior clinoid processes remained and showed indistinctly. The appearance suggested that a tumor mass extended into the sphenoid sinus. There was also evidence of intracranial pressure in the fact that the cranial sutures were more or less separated.

It was unfortunately too late, when this patient was admitted to the Philadelphia Hospital, to take his visual fields. In these cases, as is well known, a bitemporal hemianopsia is sometimes seen in the early stages, caused by pressure on the optic chiasm. Other forms of hemianopsia, as a blotting out of the superior halves, have been noted.

SURGICAL REPORT BY DR. FRAZIER

Through the courtesy of Dr. Lloyd, the patient was transferred from the Philadelphia General Hospital to my clinic at the University Hospital, where the operation was performed. The roentgenogram showed such undoubted structural changes in the sella turcica that there could be no doubt as to the seat of the lesion, although most of the symptoms peculiar to pituitary lesion other than involvement of the tract were conspicuous by their absence.

In preparation for the transfrontal approach to the hypophysis by the route which has been adopted in my clinic, the size of the frontal sinuses is studied in the roentgenogram and by transillumination, and if one sinus is smaller than the other, this determines the side on which the operation is performed. From a comparative study of the methods of determining the size of the sinuses by transillumination and with the roentgenogram, we have found the former very much more reliable or, to be more accurate, I have found the roentgenogram quite misleading and not to be relied on.

The following is a description of the operation:

Under intratracheal anesthesia an incision was made beginning at the external angular process following the curve of the supra-orbital ridge to the median line. The second limb of the incision extended upward exactly in the median line 1 inch within the hair-line and the third limb ran within the hair-line down to a point on a level with the external angular process. The inner margins of the incision were dissected free for ½ to ¾ inch, a section of the frontal bone was made with the spiral osteotome, and an osteoplastic flap reflected, exposing the frontal lobe. In fashioning the flap care was taken to avoid opening the frontal sinus which in this case extended ¾ inch from the median line, and an equal distance above the supra-orbital ridge. With a Hey saw the supra-orbital ridge was sectioned obliquely, so that the piece to be resected was wedge-shaped. This is an essential step in the technic from the cosmetic point of view, as when this wedge-shaped piece of bone is replaced the contour of the supra-orbital ridge is preserved; the bone fits snugly in place and by its shape cannot be displaced below its proper level. With a pair of forceps the supra-orbital ridge thus sectioned was grasped and wrenched free, carrying away with it a portion of the wall of the orbit. What remained of the orbital roof was removed with rongeur forceps down to, but not including, the roof of the optic foramen. With two retractors, one in the hand of the assistant, the orbital contents were displaced somewhat downward and outward and the frontal lobe elevated. (I have found that, if the dura is punctured as soon as it is exposed, the continuous escape of cerebrospinal fluid facilitates the elevation of the frontal lobe.) The patient's head was now in the Rose position and, with artificial illumination, I selected a point in the dura at which to make a horizontal incision 0.5 cm. above the base of the skull from one anterior clinoid process to the other. The retractor was passed through the dural slit and, by gentle upward pressure, I laid bare a soft, reddish-gray mass which filled the sella turcica. This was removed in part. The bone flap was then replaced, a small wick of gauze introduced into the posterior angle, and those edges of the wound not within the hair-line were closed with great precision.

The operation was not attended with any special difficulty and confirmed the opinion I had already entertained as to the ease with which the sella could be uncovered. During the period of convalescence there was a marked edema of the face and somewhat of the neck on the affected side. Whether or not this is due to the escape of cerebrospinal fluid into the cellular tissue, I do not know, but whatever the cause may be, this phenomenon is not peculiar to this operation, as I have observed it in a number of operations where the flap is reflected from the frontal rather than the parietal region.

Dr. Lloyd has already made an interesting comment on the pains of which the patient complained before the operation. After the operation he complained more or less bitterly off and on for two weeks — less as the time went on — of pains in his extremities, but especially in the thorax at the base of the chest. These pains were the most conspicuous and the only feature of interest in the postoperative period. The patient was allowed to get up one week after the operation and was discharged from the hospital three weeks later. During this period some observations were made on the effect of pituitary feeding on the blood-pressure. Systolic pressure had been unusually low before, during and after the operation, varying from 90 to 95 mm. Hg. Under the continued use of pituitary extract in ascending doses there was not the slightest variation in the blood-pressure. Negative results were obtained also from the use of epinephrin. On several occasions during these observations there were sudden and unaccountable rises in temperature. The histologic examination of a portion of the specimen removed showed it to be a sarcoma with telangiectatic characteristics. Unfortunately the advanced stage of atrophy of the optic disks precluded the possibility of any improvement in vision.

In closing, I should like to emphasize the many advantages which the transfrontal operation has over the transsphenoidal methods. The facility of exposure, the opportunity of determining with some degree of accuracy the extent of the tumor, the avoidance of such contaminating influence as the secretion of the nasal mucosa, the splendid cosmetic results; these and other minor considerations should be given credit when any comparison of methods is made. To be sure, I have only applied the method to four cases, but in each of these the results were equally satisfactory and there were *no fatalities.*

THE INVARIABLE BLOOD-STAIN

B. G. R. WILLIAMS, M.D.
PARIS, ILL.

For years I have used in my laboratory a method for the staining of blood-films which has proved so satisfactory from all points of view as to have earned the term "invariable." The idea is not original with me, but is based on two well-known principles, combined, modified and finally perfected. First of all, single films are best fixed by burning in absolute alcohol; a proper mixing of eosin with Ehrlich's acid hematoxylin gives an excellent stain, one which proved its worth before the panoptic formulas became so popular.

This method is especially suited to the needs of the general practitioner, the man who desires invariable results and who cannot become proficient in technic. Certain men, who do considerable blood work, are now using the "invariable" almost routinely. Several of these have prevailed on me to publish the formula and technic; and this will perhaps justify the addition of another to the several dozen good ones now in general use.

FORMULA AND TECHNIC

This stain does not fix. Briefly, it consists of a nuclear part, a special hematoxylin, and a cytoplasmic part, water soluble eosin. In 312 c.c. of a 3-months' ripened Ehrlich's hematoxylin, 0.1 gm. of the eosin is dissolved and the mixture filtered, if necessary. It is now ready for use, and, if tightly corked, may keep indefinitely, even improving with age. The mixture will appear rather thick, but if it becomes too thick a few drops of absolute alcohol may be added.

The technic is simple: Merely fix with burning absolute alcohol, and, after cooling, immerse the preparation in the stain for fifteen minutes. Then wash in tap-water and dry. First of all light a burner (this insures prompt ignition of the alcohol before any of the erythrocytes suffer injury), seize the slide bearing the dried film and, with suitable forceps, hold with film face upward. Quickly cover with absolute alcohol. Shake off excess and then ignite in the flame, removing preparation immediately from the flame. The alcohol will flash off, leaving a dry and perfectly fixed film. Ignition must be prompt and alcohol absolute.

Permit the slide to cool and then place in Coplin jar filled with the "invariable." After fifteen minutes, remove the slide and wash in tap-water. Dry between blotters or by gentle heat according to standard methods. Staining solution may be used many times.

ADVANTAGES OF THE METHOD

1. The presence and precise nature of all anemias, leukemias and leukocytoses may be determined by use of the invariable stain. Eosinophilia in parasitic diseases, as well as basophilic alterations in plumbism, may be easily demonstrated. This completes the qualifications demanded of any stain so far as every-day work is concerned.

2. This staining method is reliable as well as rapid. The Wright's method is rapid, but not reliable, and this objection holds with men who do considerable work. I have seen many a poor Wright's stain in some of our best laboratories. For routine work, the physician can scarcely afford to waste time on a method which is not invariable. Unless he does considerable blood work, he will meet trouble with the Wright's technic. More than this, he will need to supply himself with many films in each case, for unless he is expert or lucky, he will not always be successful. I consider Wright's method the best of the popular formulas, but it should be used only when staining for the plasmodium, or in other special blood studies, especially when controls are needed.

3. Of all nuclear stains, this is the most beautiful. The nuclear figures are clearly cut and deeply stained.

4. Of all methods of blood-staining, this is the simplest. The technic is so easily applied that the first attempt is as successful as subsequent attempts. Laboratory skill counts for but little, and a failure amounts almost to an acknowledgment of stupidity.

FURTHER NOTES ON TRANSFUSION BY MEANS OF GLASS CYLINDERS

A. R. Kimpton, M.D., Boston

An article entitled "A New and Simple Method of Transfusion" appeared in The Journal recently. The following case is reported to show further the advantages of this method.

History.—A man aged 37 was knocked down by an automobile, receiving a compound fracture of the skull with crushing trauma of the brain. As I am reporting this case in order to bring out the technic of the transfusion I shall not enter into the details except to say that the patient had lost a large amount of blood and suffered from very severe shock, and that from a therapeutic point of view the transfusion was gratifying. The head injury had been operated on by Dr. A. L. Brown of Winchester, Mass., with whom I saw the patient.

Transfusion.—A tourniquet was applied on the upper arm of the donor only tight enough to give venous congestion. Under cocain a superficial vein just below the elbow was exposed through a 1½-inch incision. This was tied off proximally, and a Crile clamp was applied distally. A similar vein was exposed in the recipient's arm. This was tied off distally, and a Crile clamp was applied proximally. With a cataract knife a slit was made in the vein of the recipient. A similar slit was now made in the vein of the donor; the clamp was opened, and a cannula of a 250 c.c. cylinder was inserted. This cylinder filled in less than two minutes (actual time was not taken). When filled the cannula was withdrawn and the clamp closed. The clamp on the vein of the patient was immediately opened, the cannula of the cylinder inserted and the cylinder emptied. A second cylinder (100 c.c.) was now filled from the same opening in the donor's vein and emptied into the same opening in the vein of the recipient. Two or more large cylinders could have been used if desired.

Remarks.—It is at once seen that this is an easy and certain performance, but it is justifiable to remark that one must understand the proper exposing and handling of blood-vessels to do it successfully. The technic is so simple that it is not necessary to have assistants trained in blood-vessel work, but the operator should be familiar with the technic of blood-vessel surgery. It is also justifiable to say that a failure probably means an error in technic.

Transfusions by vein-to-vein anastomosis have, of course, been done frequently, but the method has the difficulties and uncertainties of other direct methods. This method with glass cylinders, at least in my own hands, has proved certain and easy.

86 Bay State Road.

AN IMPROVED METHOD OF EXTRACTING OVA FROM STOOLS

H. L. McNeil, M.D., Houston, Tex.
Pathologist to the Southern Pacific Hospital

Not having seen any mention in the literature of the following method since it was first published by Yavita[1] some months ago, and since I have had such excellent results with it, I feel that another mention of it will be of value.

The technic which I have employed for the past four months, slightly modified from Yavita's, is as follows:

A particle of the stool, about the size of a cherry, is placed in a test-tube. To this are added 5 c.c. of a 25 per cent. mixture of antiformin. This is mixed well and warmed over a flame, but not boiled. Five c.c. of ether are then added and the whole shaken well. It is then filtered through one layer of gauze and centrifuged one minute (water centrifuge). Four layers are formed. In the lower layer the eggs are found.

This method is excellent, also, when one is dealing with a fluid or semifluid stool. I have found it valuable in detecting hookworm ova in stools, the capsule of the egg not being injured in the least by the mixture. I have found it superior to the method which Dock and Bass recommended, as it requires less time, and there is less residue thrown down with the ova.

Apomorphin Hydrochlorid in the Vomiting of Pregnancy and in Nausea Generally.—Having under my care at one time a patient with a severe case of vomiting of pregnancy in which various treatments had been tried but without result, I tried apomorphin, giving 1/36 grain in a teaspoon of water. The vomiting ceased and was thereafter controlled entirely by 1/36 grain in water. This was about two years ago. Since then I have used it frequently, not only in the vomiting of pregnancy but in other cases of vomiting or nausea in which an antiemetic was indicated and always with decided results. In the minute quantities used it quiets the inflamed gastric mucous membrane with no ill effects and in so doing we have a better chance to apply other remedies needed to remove the cause.—Merton Field, M.S., M.D., Canby, Minn.

MANOMETER AND SAFETY-VALVE FOR USE IN THE OPERATION OF ARTIFICIAL PNEUMOTHORAX

Lewis Sayre Mace, M.D., San Francisco

I wish to describe a simple and easily made manometer and safety-valve which I have found useful as an addition to the usual Forlanini apparatus which is used in the operation of artificial pneumothorax in lung tuberculosis.

This consists of a liter Erlenmyer flask having a three-holed stopper. Two glass tubes are arranged as in an ordinary wash-bottle, and through these tubes the gas is passed through warm sterile saline solution before its introduction into the pleural cavity. The third is a perpendicular tube open at both ends, by means of which the operator is enabled to read the intrapleural pressure at any moment while the gas is being introduced.

This manometer tube has an opening at a certain height above the level of the saline solution in the flask, so that if at any moment during the operation the positive pressure should rise to a dangerous height the liquid will overflow and no more gas can be injected until the pressure falls.

There are several advantages in passing the gas through the wash-bottle manometer before introducing it into the pleural cavity. The gas is warmed and moistened by passing through the warm saline solution and is less likely to cause unpleasant sensations and so-called pleural reflexes. There is no necessity for switching the manometer on and off during the operation, for the pressure, both positive and negative, is constantly before the operator.

On account of the ever-present danger in these operations of high intrathoracic pressure with the possibility of gas emboli resulting, the safety-valve feature of this manometer is most important.

It is surprising in using this apparatus how often one becomes aware of sudden rises of intrapleural pressure due to coughing or deep breathing of the patient. These sudden rises are most often noticed in those operations complicated by pleural adhesions, and in these cases it is practically impossible to avoid occasional high pressure except by a safety-valve of the kind I have described.

The wash-bottle manometer has still another use which in some cases becomes an important one. Should too much gas be injected and symptoms of dyspnea and cardiac pressure occur, it may easily and quickly be transformed into a syphon by changing the direction of the wash-bottle tubes and closing the manometer tube and withdrawing the necessary amount of gas.

240 Stockton Street.

A CASE OF PROLAPSED CORD

Horace Eddy Robinson, M.D., New York
Assistant Physician to the Outpatient Department, Bellevue Hospital

From the point of view of the general practitioner, prolapsed cord is a serious complication and one which is liable to be met at any time. The following case is therefore of sufficient importance and interest, I believe, to justify its report. The patient, Lena C., a primipara aged 20, was examined during the eighth month and found to be in normal condition. She went into labor at term about 9 p. m. Labor progressed favorably until 10:45 the following morning, when the membranes ruptured. The patient was immediately put to bed, and it was noted that the cord was in the vagina. The knee-chest position was immediately assumed, and an unsuccessful attempt at replacing the cord was made. Cord pulsation was 132 and fairly strong. The patient was instructed to remain in the knee-chest position. Morphin was given, and assistance sent for. Following a second injection of morphin the pains were greatly reduced in frequency and strength. Assistants did not arrive until 12:10 p. m. During this period, the patient had remained in the knee-chest position and counter-pressure was exerted against the vertex by means of the examining fingers in the vagina. At this time she was put on the table and anesthetized. Version was performed, and without difficulty a living child was delivered at 12:43 p. m. Mother and child made an uneventful recovery.

SUMMARY

Membranes ruptured, prolapsing cord at 10:45 a. m.; patient immediately assumed knee-chest position; uterine contractions were controlled by morphin; counter-pressure on vertex relieved compression of cord. Just prior to version, the cord pulsation was 110, showing a drop of twenty beats per minute. Handling of cord was avoided as much as possible. Child was delivered two hours after prolapse, and was resuscitated without great difficulty.

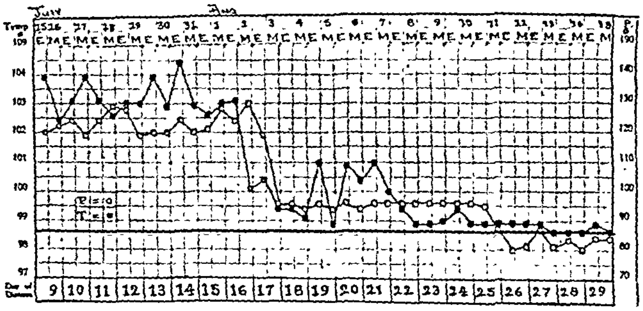
11 West Eighty-Eighth Street.

A SPORADIC CASE OF TYPHUS FEVER

Harold Hastings Newman, A.B., M.D., Washington, D. C.

At the meeting of the Association of American Physicians, in Washington, May 6, 1913, Dr. John F. Anderson,[1] Director Hygienic Laboratory, United States Public Health Service, called the attention of the medical profession to the existence of typhus fever in Boston and New York. He expressed the opinion that typhus fever was unrecognized in other large American cities and stated, "the possibility should ever be borne in mind that it may acquire virulence and epidemic prevalence." On account of the preceding statements, I report the following case of typhus fever.

Patient.—A. C., a girl aged 12, of Bohemian parentage, had attended school in Baltimore, at the House of the Good Shepherd, from December, 1912, till March, 1913. She had lived on a farm in the District of Columbia during the past year. The family and personal histories are unimportant. The present illness began Friday, July 18, 1913, with severe symptoms, including intense headache, which continued. On Tuesday, July 22, the patient was seen by a physician. She had a macular rash and a temperature of 104.8 F. The physician's impression was that it was a case of typhoid fever. Wednesday, July 23, another physician saw the patient and said she had a "rash." Her temperature ranged from 104 to 105 F on this and the next day. The attendant gave the opinion that it was scarlet fever. The patient was sent to the scarlet-fever ward of the Garfield Memorial Hospital Annex, Friday, July 25.



Pulse and temperature record in case of typhus fever in girl of 12, ending in pseudocrisis on sixteenth day of the disease.

Examination.—The patient suffered from severe headache and great prostration. She was hyperesthetic, crying out at even gentle touches of her body. Her hair was infested with "nits." Her ears were negative as to signs. The conjunctivae were congested. There was no nasal discharge. The soft palate was slightly reddened and showed several small (3 mm.) ecchymoses. Her tongue was coated and the pharynx was faintly injected. The lymph-nodes were not enlarged. Signs in lungs and heart were negative. She had no cough. The liver and spleen were not palpable. The deep reflexes were normal. Kernig's sign was suggestive. The neck was not rigid. Over her entire body, more marked over the dependent areas, was a macular rash, with the macules about 3 mm. in diameter, rusty colored and unmodified on pressure. Blood examination showed hemoglobin, 85 per cent.; red blood-cells, 4,500,000; white blood-cells, 5,360. Widal negative. Dr. Goldberger of the Public Health Service made a blood-culture and an intraperitoneal inoculation of a guinea-pig, with negative result. The negative reaction in the guinea-pig is not unusual, Dr. Goldberger finds. The stool examination and culture for typhoid bacilli were negative. Urine examination was negative except for positive Diazo.

---

[1] Anderson, John F.: The Problem of Typhus in the United States, The Journal A. M. A., June 14, 1913, p. 1845.

Course of Disease.—The patient had a continuous remittent fever which ended in "pseudocrisis" on the sixteenth day of the disease. This and the pulse-rate are shown on the accompanying chart.

Tuesday, July 29, dusky mottled-appearing macules were first noted on the face and neck. On this day some petechial macules were noted, among others on the feet and buttocks. Next day, the petechiae were numerous and diffuse over the body, especially over the elbows. With the temperature fall on Friday, August 2, the rash began to fade. By August 13 it had disappeared from the body, remaining faintly on the face and neck, and soon was invisible.

The case, typical typhus fever, was a puzzling one for a time. Various diagnoses were offered, namely, typhoid fever, scarlet fever, measles, cerebrospinal meningitis and Henoch's purpura. My experience in this case leads me to agree with Dr. Anderson that unrecognized typhus fever is prevalent. I hope this example will stimulate the medical profession to watch for such cases.

The diagnosis in this case was confirmed by Drs. Louis Mackall, H. P. Parker and by Drs. John F. Anderson and Joseph Goldberger of the United States Public Health Service.

Garfield Memorial Hospital.

A Case of Exophthalmic Goiter Apparently of Syphilitic Etiology.—T. W., a man aged 34, married, contracted syphilis six years ago, for which he was treated by iodid and mercury. He persisted in this treatment for two years and to all intents and purposes was cured. One year ago last June he developed the classical symptoms of exophthalmic goiter. He then consulted his family physician, who used mercurial medication with no appreciable benefit. This practitioner informed me that while under his care the patient's pulse varied from 120 to 160 per minute. He next consulted a local doctor and received a little benefit from his treatment, so that when he consulted me May 19, 1913, his pulse-rate was 103 per minute. The exophthalmos was the most prominent symptom. The patient's eyeballs protruded so markedly as to be startling and the goiter was about as large as an English walnut. He had only a slight tremor. On July 1, when I administered 0.6 gm. salvarsan intravenously, his condition was the same. July 18 his pulse was 94. Five days later he received a second injection of salvarsan of the same amount and on July 28 a third. August 1 his pulse was 86 per minute and the exophthalmos had quite noticeably diminished. He received a fourth and last injection on August 4. August 14 his pulse was 83. The last time I saw the patient, August 26, after sitting quietly for fifteen minutes, his pulse was 80 and he had no exophthalmos. The tremor, too, had disappeared. The appearance of the mucous membrane had improved markedly as a result of the treatment, the drug having acted as a hematinic in his case.—Harold J. Levis, M.D., Rochester, N. Y.

Cancer and the Surgeon.—I am, of course, well aware that all cases of cancer of the stomach, unhappily, do not come to the surgeon. No one but the surgeon can do any good to patients so afflicted. Yet there is a strange timidity of approach to the surgeon which is unaccountable, and far too often the favorable period in the history of a case is allowed to slip away before any recognition of the real conditions is attempted.—Sir Berkeley Moynihan, Address in Surgery, Brit. Med. Assn., 1913.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLE HAS BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. ITS ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

AGGLUTINATING SERA FOR DIAGNOSTIC PURPOSES.—These are the sera of animals (horses) immunized against various bacteria. The serums are dried and powdered and marketed in packages containing a definite weight of the powder. For use the powder is dissolved in water to make a solution of a definite strength which constitutes the agglutinating titer. This solution is added to a suspension of the bacterium to be tested, and after incubation for a certain period the mixture is examined. The clumping of the bacteria may be determined microscopically by observing whether the bacteria have sunk to the bottom of the container or the process of agglutination may be watched under the microscope.

H. K. Mulford Co., Philadelphia, Pa.

Agglutinating Serum for the Identification of Bacillus Paratyphosus A.—Marketed in sealed ampoules containing each 1 gm. of the dried serum having the agglutinating titer 1 to 20,000. Intended for use by the macroscopic method, the reading being taken after 24 hours.

Agglutinating Serum for the Identification of Bacillus Paratyphosus B.—Marketed in sealed ampoules containing each 1 gm. of the dried serum having the agglutinating titer 1 to 50,000. Intended for use by the macroscopic method, the reading being taken after 24 hours.

Agglutinating Serum for the Identification of Bacillus Typhosus.—Marketed in sealed ampoules containing each 1 gm. of the dried serum having the agglutinating titer 1 to 24,000. Intended for use by the macroscopic method, the reading being taken after 24 hours.

Therapeutics

TYPHOID FEVER

(Concluded from page 1537)

TREATMENT OF THE FREQUENT COMPLICATIONS

The only complications that will be here discussed are failure of the circulation, insomnia, intestinal hemorrhage and perforation.

Very generally, if a typhoid patient is properly managed, the heart will not be very rapid and the pulse tension will be good for the first two weeks without any artificial assistance, and the heart may be all right throughout a mild attack without such assistance. The cup of coffee in the morning gives a caffein stimulation to the heart, and if it has been accustomed to such stimulation it is certainly good treatment. In children, who are not used to coffee or tea, a cup of tea occasionally may be of medicinal value.

Alcohol should of course never be used as a cardiac stimulant. On the other hand, in small doses, as above stated, it may be used as a nutriment. In such small doses it probably has very little effect on the circulation. At times, if the patient has been used to considerable daily amounts of alcohol, it may be advisable not to stop it, much as we would not stop a morphin habit during an acute illness. At times there can be no question (and those who deride the use of alcohol in typhoid fever have no justification in disputing the fact) that with a high, bounding pulse, flushed face, dry skin, rapid heart, and heavily coated tongue, sometimes the proper dose of alcohol will lower the blood-pressure, dilate the peripheral vessels, cause perspiration and more radiation of heat, and relieve the troubled heart, and at the same time moisten a dry tongue and improve the general condition. On the other hand, the majority of patients do not need alcohol, and if too much alcohol is given the reverse of the above good condition occurs; the patient is excited both cerebrally and circulatorily by the alcohol, and its activity is harmful. It cannot be too strenuously urged, however, that when a heart fails and the blood-pressure is low, alcohol should not be given, as it will render the condition worse.

The most overused to-day of all drugs is strychnin, and part of its overuse occurs in typhoid fever. It has been shown that it generally does not raise the blood-pressure in serious illness, even in large and frequent doses. Therefore, in acute heart failure, large doses should not be given. If there is cerebral excitation, sleeplessness, restlessness, and nervous irritability generally, strychnin is certainly contra-indicated, and many times it is the cause of the typhoid patient being restless and sleepless. If there is a so-called "typhoid state," with more or less tendency to stupor, with sluggish nerve centers, strychnin is doubtless the drug of choice. It is perhaps wise, when the pulse tension flags from lack of tone of the muscular contractions of the heart in the third or fourth week of typhoid fever, to begin small doses of strychnin, as tending to activate all of the nerve centers, and in small doses to stimulate the heart to proper activity.

It is rarely advisable to give more than 1/30 of a grain of strychnin once in six hours, although, if deemed advisable, such doses may be administered hypodermatically. It will not save a heart that is going to fail; on the other hand, it may cause a heart to become irritable and rapid, the heart not seeming to have its normal diastole and rest. At the same time it stimulates, in large doses, the central nervous system to the disadvantage of the whole organism.

It is not the purpose of this article to discuss the whole subject of the treatment of cardiac failure, but suffice it to say that perhaps in pituitary extract[4] we have a preparation (which is presented to us in aseptic ampoules) that when administered hypodermatically may be of marked advantage in these cases of heart failure. The action of glandular extract is of more value for such cases than is the suprarenal extract.

The value of camphor as a nervous and cardiac stimulant is now pretty generally understood. Proper preparations of camphor may be administered hypodermatically, or it may be given in one of the well-known preparations by the mouth.

Sleeplessness in typhoid fever, especially during the early stages, is a frequent complication; but, to reiterate, the proper management of the bowels, the proper management of the room, and the institution of more or less open-air treatment (at least plenty of fresh air from open windows), the regulation of the diet, and the withholding of any unnecessary stimulant drug will generally allow these patients to sleep without any medication. An absolutely sleepless patient, however, must be made to sleep, and perhaps a few doses of sodium diethyl-barbiturate,[5] sold as medinal and veronal-sodium, each dose consisting of 0.20 to 0.25 gm. (about 3 or 4 grains), will cause a normal sleep habit. If there is marked cerebral irritation, a dose or two of bromid or of chloral may be necessary. None of these drugs should be long repeated, and it is rarely necessary. If the circulation is weak and the patient sleepless, the safest drug is morphin, and the dose need not be large. One-eighth of a grain, or less, given hypodermatically, is ample.

Hemorrhage from the intestine requires the administration of a sufficient dose of morphin hypodermatically to stop peristalsis, and 1/8 of a grain is generally sufficient, and perhaps best combined with 1/150 grain of atropin, with the withholding of all food for at least twenty-four hours, the administration only of such water as is needed for the patient's comfort, and the application of an ice-cap or cold coil to the abdomen. If the patient shows serious anemia from loss of blood, transfusion of blood must be considered, and perhaps surgical interference.

With a diagnosis of perforation of the intestine immediate operative interference is the only treatment, and the success from such immediate operation is constantly on the increase, showing that such a procedure is not only justifiable but advisable.

CONVALESCENCE

A convalescent patient, who has been on the preceding diet, does not show the emaciation that we used to see when the typhoid patient was either starved or on an absolute milk diet. The increase in the diet should for a time not be great, as he has been having most of the kinds of food that he needs. The main object is gradually to increase the amount at regular meal times and let the intermediate feedings be of less importance and contain less nutriment.

The patient should not be raised on several pillows, and certainly should not be allowed to sit up, until his cardiac strength has returned. There is no safer estimate of such strength than a pulse that does not become rapid when he turns or moves, and perhaps he should not sit up at all until his blood-pressure is above 100 mm. at least, of course, the desired blood-pressure depending on the age of the patient. Many a continued weak heart and circulation has occurred from a seriously ill patient being allowed to sit up or walk around too soon; and the same is true of allowing him to work too soon.

These patients generally have a good appetite. If they do not have appetite, they may be given some simple bitter tonic. Perhaps one of the most essential elements that they need is calcium, and it may not be better offered than in the form of the calcium glycerophosphate, in powder or capsule, in 0.30 gm. (5-grain) doses, three times a day, after meals. If the patient has not been taking iron, he should receive iron in any simple form, perhaps in the form of the *Eisenzucker,* as above suggested.

If relapses tend to recur, and if after a sufficient length of time for complete normal eradication of typhoid bacilli the feces or urine continue to show such, the patient should be inoculated with dead typhoid bacilli, as previously suggested. Also, it is quite possible that the administration of hexamethylenamin should be continued, or if it has not been given, should be begun during the convalescent period.

It is very important to remember that as soon as a typhoid patient has recovered he should see his dentist and have his teeth carefully examined, all cavities filled, and any tendency to pyorrhea prevented.

The care of the mouth during the fever has not been described, as it is presumed that proper cleanliness and proper treatment of ulcerations are part of the hygiene of a typhoid patient.

RENAL DIABETES

Although the existence of glycosurias due to changes in the kidneys, particularly as a result of the administration of drugs like phloridzin, is well established in an experimental way, as much cannot be said in respect to the clinical cases of glycosuria which occur in man. The possibility of a renal diabetes involving an increased permeability of the kidneys analogous to phloridzin glycosuria has been suspected and has found advocates at various times since the first suggestions of Lépine[1] and Klemperer[2] in this direction. As the cases were critically studied, however, the proofs of the specific functioning of the kidneys in the pathogenesis of the glycosuria in most instances failed. It is undisputed that the development of renal lesions, especially chronic interstitial nephritis, in a diabetic may greatly reduce the excretion of sugar in the urine. That the reverse effect, that is, the elimination of sugar as the result of renal changes, may likewise take place cannot be denied on general principles. To establish the distinctly renal origin of a glycosuria it is fundamentally necessary to demonstrate that the excretion of sugar is not the result of a hyperglycemia. So long as the content of sugar in the blood is above the normal there is no occasion to conclude that an attending glycosuria has an etiology different from the usual type such as is commonly associated with perversions of pancreatic function. It is only in recent years that the technic of sugar estimation in the blood has been adequately developed and that this process has become a feature of the diagnostic study of cases of diabetes. The few data available for the earlier alleged instances of renal diabetes show a content of sugar in the blood if anything above rather than below what is now established as normal. Thus in Klemperer's oft-cited case it was 0.18 per cent. Estimations of sugar content of the blood are now so frequently made that an abundance of reliable statistics on this constant is available. For the blood-plasma of healthy man it varies between 0.08 and 0.11 per cent., the upper limit probably being at about 0.12 per cent. The figures for the total blood are not widely at variance from this.

Two criteria are essential in attempting to establish the renal origin of glycosuria. The excretion of sugar should be demonstrated to be more or less independent of the carbohydrate intake; for the glycosuria need not be entirely checked by regulation of the diet if a kidney factor rather than a more remote one is the pathogenic feature. More important, however, is the second test, namely, the demonstration that the glycosuria results in a hypoglycemia or at any rate that the sugar-content of the blood is not above the normal as is uniformly the case in the classic forms of diabetes.[3] Although such discriminating standards have been proposed only in recent years, and few cases have been tested adequately in the light of such differential diagnostic requirements, there are now a small number of records collected by reliable observers which seem to justify the real existence of a renal diabetes in man. The subject has been reviewed of late by Erich Frank[4] of Minkowski's clinic at Breslau. Sometimes the pathologic condition appears to be latent. There is no excretion of sugar until a liberal amount of carbohydrate is fed, whereupon glycosuria appears despite the fact that the blood sugar-content is well within or even below normal bounds. This seems to be peculiarly characteristic of pregnancy, so that Frank has come to the conclusion that almost every pregnant woman exhibits a latent renal diabetes which at once manifests itself when an abundance of sugar is fed.

The practical importance of recognizing a renal diabetes lies in the fact that this type does not call for a restricted dietary in the same way as does the usual human diabetes. It is too early to formulate an adequate theory as to the cause of the renal diabetes, if this shall at length be definitely established as a clinical entity. Tentatively we may assume, by analogy with the way in which a glycosuria of renal origin can be induced experimentally by drugs, that the perversion of the kidney function is the outcome of the action of a toxic substance arising, as it easily can, within the organism itself in some of the many upsets to which human metabolism is subject.

THE PROSECUTION OF QUACKS

The Chicago *Tribune* gives short shrift to medical fakers. It is one of those high-class newspapers, whose numbers are happily increasing, that refuse to pollute their pages with the advertisements of quacks. For the past two or three weeks the *Tribune* has had some members of its staff investigating the methods of Chicago advertising quacks of the "men's specialist" type, and in recent issues has given the results of these investigations. In showing up the villainous character of this disreputable business, this paper has done a distinct service to the public. When the first exposure was printed, the *Tribune* had a pertinent editorial on the subject, in which it asked the question:

---

[4] Frank, Erich: Ueber experimentelle und klinische Glykosurien renalen Ursprungs, Arch. f. exper. Path. u. Pharmakol., 1913, lxxii, 387.

> "Gentlemen of the American Medical Association and of the Chicago Medical Association, what are you going to do about it?"

And closed with the statement:

> "This obscene traffic should be rooted out. It should be destroyed in Chicago. It should be destroyed wherever it goes on in the country, and it goes on everywhere. This is work for the American Medical Association to push energetically and to insist on the authorities completing."

The *Tribune* is mistaken in assuming that it is the work or duty of the American Medical Association to take any part in the prosecution of quacks, whether they operate locally or nationally. As scientific organizations, neither the American Medical Association nor the Chicago Medical Society is morally or legally concerned with this problem. The duty devolves explicitly and directly on the officers of the law who have been elected by the people to protect them against fraud. Physicians individually and collectively, through the American Medical Association, have for years been exposing the fraud practiced on the public by the quacks and "patent-medicine" fakers. The medical profession, with but one or two notable exceptions, has been well-nigh alone in this work. Vast vested interests are involved in the dirty business of both quackery and nostrum exploitation. The powers that should have protected the public have not acted, either because the public itself was indifferent on the question — being ignorant of the menace — or because there was little to be gained and much to be lost by fighting firm-rooted evil. Public prosecutors have possibly hesitated to act because they knew that, in many instances, the newspapers whose support they desired were not only out of sympathy with such prosecutions, but were actually participating in the unholy profits of the quack and the nostrum vender.

To leave such prosecution to the medical profession is to invite the inevitable cry, on the part of the quack, of "persecution" by the "doctors' trust." With a shrewd lawyer—and the quacks employ just such men, the length of their purses being well-nigh unlimited—it is not difficult to persuade the average lay jury that the plausible quack is being haled into court, not because he has defrauded the public, but because he has incurred the enmity of reputable physicians, whom the public look on as competitors! Time and again has this fact been brought out and the quack has been found "not guilty," the prosecution has failed and the swindler has gone forth, tongue in cheek, in the pose of a persecuted, much-maligned martyr.

When a crude swindler sells to the unsophisticated a "gold-brick," the officers of the law do not hesitate to prosecute. Yet here the pocketbook only is depleted; life and health are not involved. With the medical swindler, however, it is different, and action is seldom taken unless public officials are spurred into action by forces that should never need to be invoked. It is possible, of course, that the "gold-brick" swindler would be equally immune from prosecution if influential newspapers received large advertising contracts from people engaged in the "gold-brick" industry.

Let the officers of Chicago or of Cook County, whose duty is to protect the public, proceed against these "men's specialist" quacks, exposed by the Chicago *Tribune*. Let the State Board of Health revoke the licenses of such men as are employed in these "men's specialist" offices. There is no more reason for invoking the services of the American Medical Association or the Chicago Medical Society in this work than there would be for calling on the American Chemical Society to prosecute the street faker who offers to sell for a dime a wonderful mixture for turning brass or copper into silver. All that can be asked of the American Medical Association is that it should enlighten the public on the dangers of quackery. This the Association, through The Journal, has done, is doing and will continue to do, and the effect of this enlightenment is beginning to be felt in a national movement toward purging the newspapers of the country of medical frauds and fakes. More than this should not be expected of the medical profession. In fact, it is an economic and social error to attempt to shift the responsibility for prosecutions of this sort from the shoulders where it rightly belongs.

SYPHILIS AND ACUTE YELLOW ATROPHY OF THE LIVER

The occurrence of icterus to a greater or less degree during the secondary stage of syphilis is commonly recognized as not an unusual feature of the disease. According to statistics obtained from different clinics, from 1 to 2 per cent. of the total number of cases in which syphilis is present show, during the active stage of the infection, a greater or less degree of icterus, which has generally been ascribed to the direct action of the spirochetes on the liver. It is perhaps less generally known that sometimes this icteric condition passes into a typical clinical and anatomic picture of acute yellow atrophy of the liver. During the past few years, especially, cases of this sort have been reported, and since Fischer[1] in 1908 collected from the literature about fifty reliable examples of acute yellow atrophy in syphilis, this number has been considerably increased. There seem to be no particular features which distinguish these from the cases in which acute yellow atrophy exists from other or unknown causes. One is somewhat impressed, on looking over the clinical records, with the usual failure to demonstrate the presence of leucin and tyrosin in the urine; but it must be admitted that the prevailing impression as to their presence and the text-book statements concerning the abundance of these amino-acids in the urine during acute yellow atrophy, are, on the whole, exaggerated and misleading. On the other hand, in one case of syphilitic icterus and in two infants with inherited syphilis, Buschke[2] found leucin and tyrosin in the urine by using refined methods of chemical analysis.

---

[1] Fischer: Berl. klin. Wchnschr., 1908, lxv, 905.

There are two causal probabilities for the occurrence of this fatal complication in an otherwise not particularly severe syphilitic infection. One is that the severe hepatic injury is caused by a direct invasion of the liver by the spirochetes, or by the action in the liver of poisonous substances coming either from extrahepatic spirochetes or from tissues invaded by them. In this connection it can be said that attempts to find spirochetes in the liver, both by microscopic examination and through the inoculation of animals, have generally failed, and the clinical course of the cases has not usually indicated that any unusual amount of toxic material is being formed. Another possible causative factor may be found in the therapeutic attack on the disease. Acute yellow atrophy is essentially a rapid autolysis of liver tissue whereby a large proportion of it is dissolved, and the amino-acids liberated by the autolytic enzymes are carried away in the blood and excreted, occasionally in the urine. It has been demonstrated that mercury and arsenic salts markedly stimulate tissue autolysis,[3] which raises the question as to whether these essential and specific remedies may not, at least in some instances, be responsible for the acute yellow atrophy. This possibility is supported by many of the clinical records, which show that the jaundice appeared during or shortly after the time when the patient was receiving mercurial treatment.[4] There have also been two carefully studied cases in which acute yellow atrophy occurred during treatment of syphilis with salvarsan.[5] In one of these at least, there seems little doubt that the arsenic produced the condition, for the icterus appeared a few hours after the salvarsan was injected, and arsenic was found in the liver in not inconsiderable amounts. On the other hand, it is certain that mercury and arsenic are not always responsible, for not a few cases of acute yellow atrophy have developed in syphilitic persons who were not receiving any form of treatment and, furthermore, the hepatic conditions have been seen to improve under mercury.[6]

Since, therefore, syphilis of itself can cause an acute yellow atrophy, the question arises whether we ever have the right to incriminate the metallic salts when this complication arises in syphilis. An affirmative answer is indicated by the results in such cases as that reported by Tileston,[7] in which a non-syphilitic boy was treated for sympathetic ophthalmia by mercurial inunction for two months and developed acute yellow atrophy. Fortunately acute yellow atrophy is an extremely rare complication in syphilis, but, however rare it may be, if the necessary treatment is ever responsible it should be generally so understood in order that the possibility of even remote danger may be removed.

THE INFLUENCE OF ALTITUDE ON THE BLOOD

In various discussions which have been introduced in The Journal on the physiologic influence of high altitudes on the composition of the blood,[1] attention has been directed to the need of employing experimental methods of a high degree of accuracy in the study of this subject. Much of the criticism directed at the conclusions hitherto reached has been aimed at the alleged insufficiency of the methods adopted or the inadequacy of the technic of the investigators. This applies in particular to the much-debated question of the blood-count at high altitudes and the interpretation of the actual phenomena reported. The German physiologist, Bürker of Tübingen, has devoted much attention to this special aspect of the problem. The report of his investigations, which were referred to briefly some time ago, has now been published in detail[2] and furnishes some convincing data on mooted topics. They include comparative observations made at Tübingen (altitude 314 meters or 1,030 feet) and the Sanatorium Schatzalp (1,874 meters, about 6,150 feet, and about 300 meters above Davos).

One need only make a careful survey of the extensive literature on the physiology of altitude to reach the conclusion that none of the extreme statements made in relation to it can hold. In the light of what has been observed in the past it is unlikely, for example, that altitude is, on the one hand, entirely devoid of effects on the blood or, on the other, productive of the extreme changes which have been attributed to it. Bürker's findings, which appear to result from an exceptionally careful personal investigation with every precaution to avoid experimental error, show that altitude does exert an unquestionable influence on the blood in the direction of an increase in both the number of erythrocytes and the content of hemoglobin. The increase is an absolute one, not merely relative. The red cells increased from 4 to 11.5 per cent., the hemoglobin from 7 to 10 per cent. These figures, it will be noted, are smaller than those usually given for the effect of moderate altitudes, yet they represent substantial and undeniable gains quite in harmony with other previous observations.

The responses of the different persons in Bürker's Alpine expedition varied in degree; but the qualitative examinations of the blood established the fact that no hemoglobin derivative other than oxyhemoglobin was concerned in the increment at altitudes. In agreement with most observers the adjustment of the blood to the new atmospheric conditions in ascending to higher levels occurs promptly; there is a rapid increase in the factors involved at the start followed by a more gradual continuation of the effect; but on returning toward the sea-level the blood does not resume its "low altitude" composition so promptly. There may be a prolonged delay in the adjustment and return to normal figures. This phenomenon of the "after-effect" of high altitudes on the blood is also strikingly shown in the observations of Schneider of Colorado Springs on one of the most exceptional subjects ever examined.[3] It concerns a man who for seventeen years has been the resident manager of the Summit House on Pike's Peak at an altitude of over 14,000 feet. The hemoglobin in the blood of this man decreased very slowly after his descent from Pike's Peak at the end of a six months' stay. The percentage fell from 148 to 132 in thirty days and to 122 during the following six weeks spent at the lower altitudes. The number of red corpuscles decreased from 7.7 to 7.0 millions; the total volume of the blood showed an increase of 5.4 per cent. on the sixth day and a maximum, 7.5 per cent., on the thirtieth day. Similarly the oxygen capacity of the blood did not alter immediately after the descent from the Peak, but at the end of ten weeks a marked decrease was noted, as the other changes in the chemical makeup of the blood would lead one to expect. The changes here noted agree in a general way with those observed by Douglass, Haldane, Henderson and Schneider, the members of the Anglo-American Pike's Peak Expedition in 1911.[4] The sojourn of these physiologists was, however, less prolonged than that of the resident hotel manager.

Die Wirkung auf das Blut, geprüft durch tägliche Erythrozytenzählungen und tägliche qualitative und quantitative Hämoglobinbestimmungen im Blute von vier Versuchspersonen während eines Monats*, Ztschr. f. Biol., 1913, lxi, 379.

Other incidental observations of Schneider on his unique subject are of more than passing interest. For instance, during a period of six years the arterial pressure has remained normal. The pulse-rate on Pike's Peak was about 82; the first days after the descent it remained at 60 and later accelerated to 70. The popular belief, also held by some physicians, that the chest is greatly enlarged by residence at high altitudes, has not been confirmed by Dr. Schneider. He maintains, with good evidence, that the vital capacity and chest measurements are not greater than those of men of similar physique at sea-level.

Bürker has also given attention anew to the old question of the possible effects of the electrical conditions in the atmosphere of high altitudes as well as the peculiarities of the sunshine. Nothing tangible could be made out for these factors. The controlling element in the physiologic reactions is first and last the rarefied air, in response to which the interesting adjustments are initiated.

BACTERIAL METABOLISM

Inasmuch as the cells are the ultimate biologic units in the majority of physiologic and pathologic phenomena with which the problems of medicine are concerned, it is only natural that minute attention should be devoted to these primary subdivisions of living matter. When once the mechanism and functioning of the cells shall be completely unveiled, hitherto impenetrable mysteries in the life-processes will promptly be dispelled. On general principles it would seem more rational to attempt to solve the perplexities of metabolic behavior in a relatively simple single cell or aggregation of such, rather than in a more complex organization of varied types of cells such as make up the familiar organs and tissues. One reason why the study of independent cellular performance has not been more vigorously prosecuted hitherto rests in the circumstance that there are comparatively few instances of detached simple cells available for direct experimentation or critical observation. Bacteria furnish an opportunity for the investigation of unicellular organisms with considerable ease. They differ, it is true, in a number of important directions from the cells of more complex individuals. Bacterial cells have no morphologic nucleus, although they contain nuclear material; and they divide directly by fission instead of indirectly by mitosis. Nevertheless these incidental distinctions need not stop us from considering some of the fundamental operations of both plant and animal cells in so far as they are manifested in the bacteria, the very rapid growth of which is an advantage in the direction of magnifying by reduplication the processes under consideration.

Impressed by such considerations, Kendall, Day and Walker[1] of the Northwestern University Medical School Department of Bacteriology have succeeded in demonstrating that bacterial metabolism and human cellular metabolism have certain fundamental features in common. Precisely as physiologists have long pointed out that carbohydrates spare proteins in the metabolism of the higher animals, it now appears that utilizable carbohydrates protect proteins to a very considerable degree in the case of bacteria.[2] In man this is shown by the more favorable nitrogen balance when carbohydrate is substituted liberally in the ration. In the unicellular bacteria ammonia formation can be taken as the index of proteolysis; for in them ammonia as a rule represents the final step in the degradation of the proteins, there being no available energy in it. The experiments of the Northwestern University investigators with a variety of strains indicate clearly that when bacteria are offered a choice between utilizable carbohydrates and utilizable proteins less ammonia is formed than when sugar-free mediums are employed. Of course all organisms inevitably require a minimal amount of nitrogenous matter for purely structural purposes. But leaving this feature aside, these studies confirm on the unicellular forms the well-attested physiologic fact that the energy of carbohydrates is more readily utilized than that of protein. To this extent, at least, all cells investigated seem to have certain biochemical characteristics in common.

Current Comment

ADVERTISING THE FRIEDMANN "CURE"

Last week we told our readers that the American Medical Association had been sued by one J. J. Meyer of New York and Milwaukee for $100,000 for the articles it had published regarding the Friedmann "cure." This week two more suits have been entered against the Association apparently for the same articles. Each suit is for $100,000, one being brought under the name of Dr. T. L. Hein of New York City, the other under the name of Dr. J. S. Waterman of Algonquin, N. Y. The alleged libelous articles did not mention the names of either Waterman or Hein. Apparently these gentlemen feel that THE JOURNAL'S strictures on the exploitation of the Friedmann "cure" apply to them individually. It is fair to infer that they have put on the cap and decided that it fits. In each of the three suits ex-politician David S. Rose, "western representative" of the Friedmann concern, appears as attorney for the plaintiffs! When *Collier's* published its series of articles on "The Great American Fraud," some of the "patent-medicine" fakers started libel suits against the magazine. Every few months technical moves were made by the lawyers. With equal regularity items of "tainted news" appeared in those newspapers which catered to the "patent-medicine" interests, leaving with the careless reader the impression that the fakers had won their suits. Possibly it may be the intention of the Friedmann concern to play the same game in the present case. We may expect, from now on, that every week or so a new suit will be entered against the Association by others in the "Friedmann institute" business, each for $100,000, and each with David S. Rose as attorney. It remains to be seen whether any of these suits will be brought to trial. They may be but incidents in the advertising campaign of the disgraceful exploitation of the Friedmann "cure." We do not know of any cheaper way of getting into the newspaper than to file libel suits!

LATE RESULTS OF LUES

Now that the interest of the public concerning various sexual diseases, particularly syphilis, has been aroused, it is well to be able to place before it exact figures concerning the ultimate results of this disease rather than to hurl invective and paint imaginary horrors. Indeed, a cold analysis of such late results shows a picture as bad as that painted by writers on this subject, if not worse. A reference to the literature shows many reports, a few of which have analyzed a material consisting of large numbers of cases. Thus Pick and Bandler[1] studied 2,067 cases. Of these, sixty-four patients, or 3.1 per cent., died of tuberculosis; thirty-five patients, or 1.5 per cent., died of diseases of the nervous system; 0.6 per cent. died of liver and kidney diseases; 0.3 per cent. died from suicide and two of carcinoma. More recently Mattauschek and Pilcz[2] have analyzed the late results in 4,134 cases of lues occurring among officers in the Austrian army from 1880 to 1900. Up to Jan. 1, 1912, there was a total mortality of 546. The cause of death was ascertained in 508 of these cases. In 147 death was due to a secondary tuberculosis and in 83 to suicide; 17 patients died from aortic aneurysms and 101 of cardiovascular diseases, including myocardial degeneration and arteriosclerotic changes. Syphilis was the direct cause of death in 20 cases and produced permanent disability in 20 others. There were 91 deaths due to diseases of the nervous system, 17 to kidney disturbances and 12 to diseases of the liver. Of the remaining 3,588 patients, 198 have progressive paralysis, 113 are tabetic and 132 have developed cerebrospinal manifestations of syphilis, of whom 80 are insane. There were, therefore, 14.64 per cent. who have succumbed to the effects of their infection or are chronic invalids. It seems hardly worth while to attempt to draw conclusions from the facts and figures here presented. Their awful immensity is in itself potent to teach. These men, as officers in the Austrian army, are called by the authors "sexually enlightened"; but the enlightenment evidently did not portray the fearful dangers to which syphilis exposes its victims in such a manner as to deter them from exposing themselves to infection. Were it not for the fact that even among a large number of medical men, the definite causal relationship between progressive paralysis, tabes and other manifestations is not understood, it would seem almost incredible that these officers should not have known of the terrible power of syphilis to destroy. Of great interest, of course, will be similar observations made in another decade which will show the influence of newer methods of treatment.

INTRAMUSCULAR VERSUS SUBCUTANEOUS INJECTIONS

We are reminded by a recently published review[3] of the marked change of opinion which has come about of late in respect to the comparative efficiency of subcutaneous and intramuscular injections in the administration of therapeutic agents. Deep or intramuscular injections have been practiced by physicians for many years; not, however, in the belief that they afforded a more prompt mode of drug absorption, but rather on the supposition that the formation of abscesses was thereby more readily averted. It remained for Meltzer and Auer to demonstrate conclusively that the effects of active drugs appear earlier and with greater intensity after intramuscular injections than after subcutaneous injections.[4] Pointing in the same direction is the fact that doses ineffective by the latter mode of introduction may often exert their characteristic effect when injected intramuscularly. This is especially true when a certain concentration of active substance is called for in the circulation to induce the awaited result. Eggleston and Hatcher[5] found that for intramuscular injections the minimum dose of apomorphin to produce emetic action is half of that which provokes a similar effect on subcutaneous injection. Morgenroth and Levy[6] make the assertion in relation to the absorption of diphtheria antitoxin that the intramuscular injection of a small dose of antitoxin together with a fatal dose of toxin prevented even induration at the site of the injection, while a much larger dose of antitoxin administered subcutaneously (again with a fatal dose of toxin) was incapable of preventing the early death of the animals tested. To quote Meltzer's conclusion, it is now quite safely established that active substances are pharmacologically more effective, that is, manifest their effects earlier and with greater intensity, when administered by intramuscular than by subcutaneous injection.

WORK OF THE COMMISSION ON ELECTRIC SHOCK

Late in 1911, the president of the National Electric Light Association asked the cooperation of the American Medical Association in establishing a commission to investigate the subject of electric shock and to formulate a standard chart for the use of workmen and others for reviving persons injured by electric currents. The matter was referred to and taken up by the Council on Health and Public Instruction. After considerable correspondence and discussion, a joint commission was appointed consisting of representatives named by the National Electric Light Association, the American Institute of Electrical Engineers and the American Medical Association. After devoting nearly a year to an investigation of the entire subject, the commission, which consisted of physicians, surgeons and electrical engineers,[7] made a report and prepared a chart and handbook of instructions as to the best methods of resuscitation from electric shock. The report appeared in the *Proceedings* of the National Electric Light Association. The handbook and chart were published by the *Electrical World* in a form suitable for distribution to workmen and for display in factories, power-houses and other places in which high-power electric currents are encountered. The need for these publications was at once evident. Railways and industrial corporations asked for large numbers of copies or for permission to reprint the rules, which was in all cases readily given. A number of government boards and state boards also reprinted the chart. The government of Canada has adopted the rules officially and has called the attention of all Canadian railways to them. Requests have been received for copies in Spanish, German, French, Italian, Japanese and Magyar, and authority for reprinting the rules in these languages has been given. The National Electric Light Association itself has distributed over a hundred thousand copies. While an exact estimate is impossible, it is probable that the rules have been reprinted either in full or in abstract about five million times, and the work is still going on. At the last annual meeting of the National Electric Light Association the following resolution was unanimously adopted:

> WHEREAS, The association has accomplished a most creditable piece of humanitarian work in the issuance of its rules on resuscitation from electric shock used throughout the world and approved formally by other industries, the national government and state boards: Therefore, be it
>
> *Resolved*, That the thanks of this association be extended to the Medical Commission for its splendid results, and also to the American Medical Association, without whose active cooperation these laudable results could never have been achieved.

The work of this commission is monumental and its effects will be wide-spread. It is an excellent illustration of the valuable results which can be secured through practical cooperation between the medical profession and enlightened business men for the saving of life and the prevention of accidents.

THE FATE OF COCAIN IN THE BODY

Not long ago we called attention to the need of revision of some of the inherited traditions and current views respecting the fate of various alkaloids in the body, instancing the example of morphin which has long been supposed not to be excreted through the kidneys to any noteworthy extent.[1] Some of the prevailing conclusions in regard to the behavior of cocain appear to be equally in need of amendment in the light of up-to-date information. When it was first reported that subcutaneous administration of this alkaloid was not followed by its reappearance in the urine, this finding taken in connection with some observations of a different type made it seem plausible to assume that cocain may be destroyed in large measure by contact with animal tissues. As a matter of fact, newer experiments conducted in the pharmacologic institute of the University of Berlin[2] bring evidence that cocain may actually be excreted in decidedly large proportions by the kidneys. At first, in any period of frequent administration of the alkaloid, a tendency toward cumulative manifestations may arise; but the proportionate daily output increases with the use of the drug. According to these newest studies of Rifâtwachdani even prolonged contact with living tissues does not appear to induce a destruction of cocain. For the closely related derivative ecgonin the kidneys have likewise been demonstrated to afford an effective path of excretion.

Medical News

ARKANSAS

Emergency Hospital.—The board of managers of the Missouri Pacific and Iron Mountain Employees' Hospital Association has authorized the erection of an emergency hospital at Argenita, across the river from Little Rock. It will provide for emergency treatment of the sick and injured employees of the shops and railroad yards.

Personal.—Dr. Verne R. Stover, Little Rock, has resigned as superintendent of the city hospital, to become medical director of the St. James Hospital at Anking, China. Dr. J. B. Dooley has been named to succeed Dr. Stover. Dr. W. M. McRae has succeeded Dr. Dooley as district physician.——Dr. Jesse S. Rinehart has been appointed city health officer at Camden.——Dr. W. G. Hodges of Social Hill has been appointed physician for the Malvern and Camden Railway.

State Hygienic Laboratory.—The laboratory of the newly created State Board of Health of Arkansas, under the direction of Dr. Morgan Smith, secretary, is now ready, at Little Rock, for making laboratory tests required by physicians throughout the state. Instructions have been sent out as to the manner in which specimens should be sent in for examination and stating what work the state board is prepared to do in its laboratory. Among the activities of the board is the establishment of a state health car to tour the state for the instruction of the people in preventive medicine. The car is to be supported partially by voluntary subscriptions.

CALIFORNIA

Personal.—Dr. Max Morse, Berkeley, has been appointed instructor in physiology of the medical department of the University of California.

New Hospital.—Plans have been completed for the erection of a five-story and basement reinforced concrete hospital building in Los Angeles for the Methodist Hospital Association. The cost of the building is estimated at $100,000.——The French Hospital Association of Los Angeles is also to erect a three-story hospital at the corner of College and Castelar Streets.

New State Medical Examining Board.—October 10, Governor Johnson appointed ten members of the state medical examining board under the law passed by the last legislature. Of these men, five are of the regular school, two osteopaths, two homeopaths and one eclectic. The men appointed are as follows: Dr. Harry E. Anderson, San Francisco; Dr. William R. Molony, Los Angeles; Dr. S. H. Buteau, Oakland; Dr. Frederick, F. Gundrum, Sacramento; Dr. H. Clifford Loos, San Diego; Dr. D. L. Tasker, Los Angeles; Dr. W. W. Vanderburgh, San Francisco; Dr. Charles B. Pinkham, San Francisco; Dr. Robert A. Campbell, Los Angeles; Dr. H. V. Brown, Los Angeles.

ILLINOIS

Child Welfare Exhibit.—Peoria had its annual Child Welfare convention and exhibit, beginning October 27. Four thousand dollars were spent on the exhibit which surpassed that of former exhibits. The local management had the support and encouragement of Dr. Julia Lathrop, of the National Child Welfare Bureau and of the Russell Sage Foundation.

Names New Men on State Board.—Governor Dunne on October 28 appointed the following members of the State Board of Health: John A. Robison, Chicago, to succeed Dr. Henry Richings, Rockford, term expired; Dr. Tullis B. Lewis, Hammond, vice Dr. Perry H. Wessel, Moline; Dr. Robert D. Luster, vice Dr. Ralph E. Niedringhaus, Granite City, and Dr. Adam Szwajkart, Chicago, to succeed Dr. Charles J. Boswell, Mounds.

To Prevent Lake Pollution.—Dr. R. B. Stolp, president of the village of Kenilworth, has been instructed by the village board to commence proceedings to restrain the cities and villages of the North Shore, from polluting the waters of Lake Michigan from which Kenilworth obtains its water supply. Waukegan and Kenosha are the principal towns complained against. The action is to be brought in the United States court. The problem of the pollution of the water supply of the great population in Chicago and its neighborhood is one that must soon be met.

Personal.—Dr. Frank Davenport, Rock Island, who has been in the service of the American Smelting and Refining Co., in Mexico, has returned to the United States after having many interesting experiences in connection with the revolution in that country.——Dr. H. E. Johnson, Bloomington, will spend the winter at his home in Crescent City, Florida.——Dr. Wilcox, Amboy, after a protracted illness in the hospital at Dixon, has returned to his practice.——Dr. H. G. Schmidt, Elgin, has returned from the seat of war at Torreon, Mexico.——Dr. George F. Tyson, Evanston, has returned from a visit to Scotland.——Dr. James H. Shepperd, Peoria, was operated on for appendicitis at the Proctor Hospital, October 18.——Dr. J. S. Adsit, Danville, has been elected president of the State Medical Society.——Dr. L. B. Jolley, North Chicago, and Dr. V. J. Cokenour, Joliet, met with similar accidents in the breaking of their arms while cranking their automobiles.——Dr. T. D. Doan, Scottville, has resumed practice after spending nine months in the Modern Woodmen Sanatorium in Colorado.

Chicago

Personal.—Dr. Liston H. Montgomery has been appointed surgeon of the Eastern Division of the Chicago Great Western Railroad.——Dr. Clarence H. Wall, police ambulance surgeon, operated on for hernia October 21, is recovering rapidly.

War on Fake Medical Museums.—Chicago has begun war on the fake medical museums in the city, chiefly on South State Street. The health department has obtained warrants against the promoters of two of these museums and they have been closed.

Sanatorium for Advanced Tuberculosis.—The cornerstone has been laid of a sanatorium for advanced cases of tuberculosis, located at Fiftieth and Belmont Avenue. The structure is to cost $50,000 and is being promoted by the Jewish Consumptives' Relief Society. One hundred patients will be cared for. Dr. Theo. B. Sachs is to be the physician in charge.

IOWA

Tri-County Medical Society.—A tri-county medical society, including Monroe, Marion and Mahaska counties, was organized at Albia early in October with the following officers: president, Dr. Ernest C. McClure, Bussey, and secretary, Dr. Taylor R. Jackson, Albia.

Second District Medical Society.—At the meeting of the Second District Medical Society at Davenport, October 14, Dr. F. H. Little, Muscatine, was elected president; Dr. C. P. Howard, Iowa City, and Dr. L. B. Carson, Maquoketa, vice-presidents, and Dr. J. V. Littig, Davenport, secretary-treasurer. The 1914 meeting is to be held at Davenport.

Medical Society Elections.—The Council Bluffs Medical Society has elected the following officers: president, Dr. W. P. Hombach; vice-president, Dr. L. L. Henninger; secretary, Dr. John S. McAtee; treasurer, Dr. F. W. Dean; board of censors, Drs. A. V. Hennessy, V. S. Treynor and J. H. Cole.——At the meeting of the Benton County Medical Association at Cedar Rapids, the following officers were elected: president, Dr. G. A. Wagner, Van Horn; vice-president, Dr. J. E. Luckey, Vinton; secretary-treasurer, Dr. Theodore L. Chadbourne, Vinton.

Personal.—Dr. William Jepson, head of the University College of Medicine, Iowa City, has resigned. Dr. Jepson resides in Sioux City. Dr. W. R. Whiteis of Iowa City has been appointed to succeed him.——Dr. E. J. Walsh, Davenport, has returned from a trip to Europe.——Dr. C. C. Smead of Newton has had a stroke of paralysis.——Dr. Bert Joynt, Emmetsburg, will go to Vienna for study.——Dr. Henry C. Stanclift, Mt. Vernon, has returned from a six months' visit to England.——Dr. E. C. Ayers of Lorimer had his arm broken in an automobile accident while on a visit at Geneseo, Ill.——Dr. W. O. McDowell of Grundy Center was recently operated on at Davenport for appendicitis.

Campaign for Public Health.—Prof. L. W. Dean, Iowa City, of the University of Iowa Medical College, and president of the Iowa State Medical Society, has appointed a state council on public health education, consisting of the following members: Dr. M. M. Dolding, Cherokee; Dr. Henry Albert, Iowa City, state bacteriologist; Dr. Lenna L. Means, Des Moines; Dr. Jeannette Throckmorton, Chariton, and Dr. Paul E. Gardner, New Hampton. Subcommittees are to be appointed in the different counties throughout the state, from various civic, commercial and other bodies, who are to be asked to cooperate in a general campaign for health improvement. Subjects have been assigned which will be discussed in various places during the year. Among them are the fly and the mosquito, public school questions, the normal child, and tuberculosis. The Council on Public Health Education of the American Medical Association will also provide speakers for the campaign in Iowa.

MARYLAND

Educational Campaign.—An educational campaign for social hygiene is to be undertaken by the Maryland Society for Social Hygiene, and at a meeting held recently an educational committee was appointed to report on plans for placing the matter in an intelligible and dignified way before the schoolchildren and the general public.

Personal.—Sir William Osler has accepted an invitation to deliver the principal address at the opening of the James Buchanan Brady Urological Clinic.——Dr. Henry Barton Jacobs attended the formal opening of the International Tuberculosis Conference in Berlin, as a delegate from America.——Dr. Brice Goldsborough, who was recently a patient at Dr. Howard A. Kelly's Sanitarium, has recovered and resumed his practice.

New School for Blind.—The Maryland School for the Blind at Overlea was dedicated during the past week with elaborate exercises and in the presence of noted educators of the blind from other states. The Maryland School for the Blind has attracted considerable attention because of being the first to adopt the modern cottage system of housing the pupils instead of the old dormitory system. There are four cottages, each with accommodations for thirty, three or four teachers and a house mother.

Increased Appropriation Refused.—The Baltimore hospitals, which asked for an increased per capita of 50 cents per patient, have been refused by the Board of Estimates. For many months there has been a movement on foot to have this raised to $1, the contention of the hospitals being that they were suffering a loss under the present arrangement. At the present time there are eleven hospitals under contract with the city to care for patients who are turned over to them either by representatives of the police department or through some branch of the city charities.

MINNESOTA

Lectures on Hygiene.—Members of the State Board of Health will give a series of twenty lectures on hygiene to the students of the medical department of the university, under the direction of Dr. R. H. Mullin, Minneapolis, of the laboratory division.

Reporting Infectious Diseases.—The State Board of Health has recently made a regulation requiring the placarding of houses in which persons with tuberculosis live. This is to be enforced only when proper precautions are not taken by the patients and the inmates of such houses. Cards are also to be placed on houses in which there are cases of whooping-cough. Teachers, lodging-house managers, managers of workmen's camps, etc., are required to report cases of sore eyes, with the idea of preventing the spread of trachoma.——Dr. J. J. Kinyoun of the U. S. Public Health Service is reported as having declared that Minnesota should have a leper hospital. Fourteen cases of leprosy have been found in the state.

Personal.—Dr. C. O. Merica, superintendent of the State Training School for Boys, in Red Wing, has resigned, to take effect Jan. 1, 1914. Dr. J. F. Fulton, assistant superintendent, has become acting head of the school.——Dr. R. F. Goodwin of Minneapolis was injured in an automobile accident.——Dr. W. M. Smith of Red Wing was elected vice-president of the Minnesota State Sanitary Conference at Minneapolis.——Dr. A. E. Spalding of Luverne was elected president of the State Medical Society. He is also a member of the board of state censors. The president of the state society is selected from Minneapolis one year, from St. Paul the next year, and each third year the chairman is selected from the state outside of those two cities.

NEBRASKA

Alumni Meeting.—The fourth annual clinical alumni week of the College of Medicine of the University of Nebraska was held in Omaha October 13 to 18. An interesting scientific and social program was provided.

Personal.—Dr. J. P. Lord, Omaha, has returned after spending the summer in Europe.——Dr. G. Davis, York, has been appointed by the board of control as pathologist at the Hastings Asylum.——Dr. J. H. Vance, Omaha, was recently operated on at Rochester for gall-stones.

New University Medical School. — The University of Nebraska College of Medicine has been removed from Lincoln to Omaha. A new building has been provided for the school, which cost $115,000, and was dedicated in September. It is to be the aim of the college to be to the people of the state what the agricultural college has been to the agriculturists of the state. On the program of the college work is a series of popular lectures on medical subjects and the maintenance of a free dispensary. Seven new laboratory instructors and a clinical staff of four physicians of Omaha have been added to the faculty of the Omaha College of Medicine, which up to last year gave the last two years of the medical work in the university course. The faculty now number fifty-five in all.

NEW YORK

Court Interprets Sanitary Code.—The Sanitary Code of New York City which forbids any milk dealer to receive or have in his possession unclean milk bottles has been upheld by the court of appeals, but the court allows a reasonable time in which to clean them. The court states that this section of the sanitary code is constitutional and that its effect is to prohibit a person who receives unclean milk bottles from keeping them unclean for any length of time.——A verdict of $16,800 has been directed by the supreme court in an action brought by the state of New York against two New York milk dealers, who were accused of skimming the cream from 168 bottles of milk. In February, 1911, a similar case was tried and resulted in a verdict of $50 a can on 336 cans.

New York City

Lectures in Genito-Urinary Diseases.—A series of clinical lectures and demonstrations on genito-urinary and venereal diseases, will be given by Dr. Bierhoff every Monday evening at 8:30 o'clock at the West Side German Dispensary, beginning Nov. 3, 1913. The course is free to physicians and advanced students in medicine.

The Bulkley Lectures.—In accordance with his usual custom Dr. L. Duncan Bulkley will give a series of clinical lectures on diseases of the skin at the New York Skin and Cancer Hospital on Wednesday afternoons, beginning Nov. 15, 1913, at 4:15 o'clock. These lectures are free to the medical profession on presentation of their professional cards.

Whooping-Cough Camp.—The *Helen C. Juilliard*, the Floating Hospital of St. John's Guild, is to be used during the winter months as a whooping-cough camp. This will not interfere with the usual summer work of the Floating Hospital. One of the features of the work will be the instruction of the mothers in the care of their children at home.

Gifts to Columbia.—At a meeting of the trustees of Columbia University on October 6, it was announced that the family of the late W. Bayard Cutting had given $200,000 as a fund for the maintenance of traveling fellowships which will be open to graduates of the university, including the College of Physicians and Surgeons. It was announced at the same time that Mr. Clarence H. Mackay had given $2,500 for surgical research and that an anonymous donor had given $1,000 for salaries in the department of physiology.

NORTH CAROLINA

Whole-Time County Health Officers.—Of the 100 counties of North Carolina, ten have appointed health officers who devote their entire time to the work, receiving salaries of from $1,800 to $2,500. At a conference of these officers held recently in Raleigh, with a view to better instruction in their duties and a standardization of their work, the following were present: Drs. A. N. Cox, Columbus County; Archibald Cheatham, Durham, Durham County; W. M. Jones, Guilford County; H. H. Utley, Benson, Johnson County; J. Strickland, Nashville, Forsythe County; Samuel Ellington, Wentworth, Rockingham County; B. W. Page, Lumbarton, Robeson County; G. M. Cooper, Clinton, Sampson County; D. E. Sevier, Asheville, Buncombe County, and C. T. Nesbitt, Wilmington, New Hanover County.

OHIO

Cincinnati

Academy of Medicine.—Dr. Winford H. Smith, superintendent of Johns Hopkins Hospital, read a very excellent paper before the academy, entitled "The Hospital Superintendent." It was discussed by Drs. Oliver, Geier and Holmes.——Dr. Charles A. L. Reed, president of the Academy of Medicine, has been officially advised that the invitation extended by the academy to the Mississippi Valley Medical Association to meet in this city in October, 1914, was unanimously accepted at the session just concluded in New Orleans.

Personal.—Dr. Gustav Zinke, for twenty-five years past the president of the medical staff of the German Deaconess Hospital, has resigned his position, Dr. Max Koehler having been elected as his successor. Dr. Zinke will retain the distinction of honorary president.——Dr. J. H. Landis, city health officer, has been elected to membership in the New York Milk Commission, a national organization whose purpose is to create a demand for pure milk.——Dr. E. W. Mitchell has been chosen to occupy the chair of internal medicine in the medical department of the university, a vacancy caused by the death of the late Dr. Frederick Forchheimer.——Dr. O. P. Geier, City Superintendent of Charities and Correction, has been elected vice-president of the Ohio Child Welfare League.

PENNSYLVANIA

Insane Fund.—The city treasurer of Philadelphia paid to the state treasurer $18,961.19 for the care by the state, of the insane of the County of Philadelphia, for the year ending May 31.

Personal.—Dr. C. Johnstonebach of Bethlehem, and Dr. William A. Stewart of Pittsburgh, were appointed by Governor Tener, October 20, as members of the Bureau of Medical Education and Licensure.

University Appointments.—The following new appointments to the faculty of the School of Medicine, University of Pittsburgh, have been made: Dr. W. E. Gardner, assistant demonstrator in anatomy; Dr. J. W. McMeans, assistant in clinical pathology and demonstrator in pathology; Dr. J. C. Irwin, instructor in obstetrics; Dr. R. J. Cary, demonstrator in medicine; Dr. Arthur Miltenberger, assistant demonstrator in obstetrics; Dr. J. H. Seipel, assistant demonstrator in obstetrics, and Mr. Orville J. Walker, assistant in physiology and pharmacology. The following increases in rank have likewise been provided for: Dr. Chris Gardner, from assistant demonstrator to demonstrator in anatomy; Dr. W. L. Croll, from instructor to assistant professor in obstetrics.

Vision Conservation Society Formed.—Acting under auspices of the commission appointed by the Medical Society of the State of Pennsylvania, laymen and doctors have formed the Pennsylvania Society for the Conservation of Vision. Aroused by learning that this country has 100,000 blind people, an active campaign is under way against ophthalmia neonatorum, needless eye injuries in the trades, trachoma, wood alcohol, wrong lighting of buildings and like causes. In addition to a large number of distinguished laymen, acting as advisory members, the Commission on Conservation of Vision includes Dr. Wm. Campbell Posey, Wills Eye Hospital, Philadelphia, chairman; Dr. Wm. W. Blair, University of Pittsburgh, Pittsburgh, Pa.; Dr. Clarence P. Franklin, Philadelphia; Dr. C. M. Harris, Johnstown, Pa.; Dr. Edw. B. Heckel, Pittsburgh, Pa.; Dr. T. B. Holloway, University Hospital, Philadelphia, secretary; Dr. Wendell Reber, Temple University, Philadelphia; Dr. Edward Stieren, Pittsburgh, Pa.; Dr. Lewis H. Taylor, president of State Society, Wilkes-Barre, Pa.; Dr. Wm. Zentmayer, Wills Eye Hospital, Philadelphia; Dr. Samuel G. Dixon, Commissioner of Health of the State of Pennsylvania, Harrisburg, Pa., honorary chairman. Membership, costing $1 a year, is asked from all persons, and the secretary may be written to direct.

Philadelphia

Hospital Cornerstone Laid.—The cornerstone laying of the new Jewish Maternity Hospital at Fifth and Spruce Streets, was celebrated on October 20. The hospital is being erected by the Jewish Maternity Association, which was founded in 1884, and has cared for 7,000 mothers in this city as well as 5,000 mothers at seaside resorts. The new building will cost $60,000, and it will be equipped in the most modern and complete manner.

Jefferson Hospital Section of Diseases of the Chest.—The trustees of Jefferson Medical College announce that the new Department for Diseases of the Chest is ready for occupancy. The new department was made possible by the purchase of the buildings formerly, occupied by the Phipps Institute and located at 236-238 Pine Street. These buildings have, at a cost of $20,000, been completely renovated and modernized and every facility afforded for the efficient care of patients suffering with diseases of the chest.

Personal.—Dr. J. Torrance Rugh, associate in orthopedic surgery, in Jefferson Hospital, has been appointed orthopedic surgeon to the Philadelphia General Hospital, to succeed Dr. H. Augusta Wilson, resigned.——Dr. Julius Blechschmidt has been appointed chief clinical assistant in the Pediatric Department, Jefferson Medical College Hospital.——Dr. Frances Heath, of the Woman's Medical College, of this city, sailed for Pekin, China, October 15. She will become an instructor in anatomy and surgery in the Union Medical College of Pekin.——Dr. W. D. Robinson has been elected a member of the Board of Directors of the Child Federal of this city.

VIRGINIA

State Society Meeting.—The annual meeting of the Medical Society of Virginia was held in Lynchburg, October 21-24, and the following officers were elected: president, Dr. Stephen Harnsberger, Catlett; vice-presidents, Drs. R. C. Bryan, Richmond; John Staige Davis, University, and B. R. Gary, Newport News; delegates to the American Medical Association, Drs. H. E. Anderson, Farmville, and Kirkland Ruffin, Norfolk; alternates, Drs. R. M. Taliaferro, Lynchburg, and Lomax Gwathmey, Norfolk, and councilors-at-large, Drs. H. Stuart McLean, Richmond, and George J. Tompkins, Lynchburg.

GENERAL

The Eustachius Celebration.—The town of San Severino in Italy was the scene in September of a gathering of scientists to honor the quadricentennial of Bartolommeo Eustachius, the great anatomist of the sixteenth century. G. Bilancioni reported several new finds in the numerous works of Eustachius, demonstrating his priority in certain other discoveries not generally credited to him.

Mississippi Valley Medical Association.—The thirty-ninth annual meeting of the Mississippi Valley Medical Association was held in New Orleans, October 23 to 25, under the presidency of Dr. Albert E. Sterne, Indianapolis. Cincinnati was selected as the place of meeting for 1914, and the following officers were elected: president, Dr. D'Orsay Hecht, Chicago; vice-presidents, Drs. W. W. Butterworth, New Orleans, and Willard J. Stone, Toledo, Ohio; secretary, Dr. Henry Enos Tuley, Louisville, Ky. (reelected), and treasurer, Dr. S. C. Stanton, Chicago (reelected).

Bequests and Donations.—The following bequests and donations have recently been announced:

St. Luke's Hospital, New York City, $50,000; the House of Rest for Consumptives and the New York Association for Improving the Condition of the Poor, each $10,000, by the will of the late Herman Casper von Post.

Philadelphia Home for Incurables, for the endowment of a room in memory of Robert and Elizabeth Cresswell, $5,000; the Sanitarium for Sick Children and the Children's Country Week Association, Philadelphia, $500, by the will of the late Miss Elizabeth P. Cresswell.

Wills Eye Hospital, Philadelphia, $50, by the will of the late Thomas Seery.

Federation of Jewish Charities, New York City, $2,000; Jewish Seaside Home, and Jewish Day Nursery, both in New York City, $250 each, and Mt. Sinai Hospital, New York City, $200, by the will of the late Henry Jonas.

Johns Hopkins Medical School, Baltimore, $1,500,000; Barnard College, New York City, $200,000; Wellesley College, Wellesley, Mass., $200,000; Ripon College, Ripon, Wis., $50,000. These donations were announced October 24 by the General Education Board, founded by John D. Rockefeller, and are gifts by Mr. Rockefeller.

Formation of National Radium Institute.—Dr. Charles L. Parsons, chief of the Division of Mineral Technology, Bureau of Mines, has been authorized by the director of the Bureau of Mines to announce that a cooperative agreement has been entered into with the newly organized National Radium Institute whereby the bureau obtains the opportunity of a scientific and technological study of the mining and concentrating of carnotite ores and of the most efficient methods of obtaining radium vanadium and uranium therefrom, with a view to increased efficiency of production and the prevention of waste. The National Radium Institute was recently incorporated with the following officers: Howard A. Kelly of Baltimore, president; Curtis F. Burnam of Baltimore, vice-president; Archibald Douglas of New York, secretary and treasurer; James Douglas of New York, and E. J. Maloney of Wilmington, additional directors. The institute has obtained the right to mine twenty-seven claims in the Paradox Valley region, among which are some of the best mines in this richest radium-bearing region of the world. Under the agreement with the Bureau of Mines the technical operations of the mines and mill are to be guided by the scientific staff of the bureau. All processes, details of apparatus and plant and general information gained will be published for the benefit of the people. The institute is supplied with sufficient funds to carry out its plans. It has been formed for the special purpose of procuring enough radium to conduct extensive experiments in radium therapy with special reference to the curing of cancer.

Gift to Johns Hopkins.—The General Education Board, founded by John D. Rockefeller, has announced a gift of $1,500,000 to the medical school of Johns Hopkins University. It is to be known as the William H. Welch endowment for education and clinical research, as a recognition of Dr. Welch's distinguished service to the cause of medical education in America. This is the greatest gift ever made by the board to a single institution of learning. The proposed plan of spending the money opens the way for a new era in medical science. Briefly it is this: To so reorganize the medical school as to pay out of the income from the gift such salaries to the men who occupy the chairs of medicine, surgery and pediatrics and to their assistants as will enable them wholly to drop their private practice and devote their entire time, ability and lives to the advancement of their particular branches. The departments which it affects are at present presided over by the following: professor of medicine, Dr. Lewellys F. Barker; professor of surgery, Dr. W. S. Halsted; professor of pediatrics, Dr. John Howland. The first problem confronting the trustees of the Hopkins University, which will administer the fund, will be to persuade the men now at the head of these departments to withdraw from the large practice which each has and accept the salary which the fund will afford. What this salary will be has not been determined, but judging from the income which will be derived from the fund it is speculated that $10,000 may be the sum offered to the heads of the three departments. About twenty physicians are affected. The plan takes in not only the heads of the departments, but also contemplates the appointment of associate professors and assistants. The Johns Hopkins University and the Johns Hopkins Hospital have been the recipients of many large gifts, besides the original gift of Johns Hopkins, for the establishment of the hospital, exclusive of the ground on which the hospital stands, amounting to $2,941,603.35.

CANADA

Flower Day Funds.—Violet and Rose day in Montreal, Saturday, October 18, held in aid of the Royal Edward Institute for the Tuberculous and the School for Cripple Children, netted $25,000 for those institutions. Two thousand women, girls and boys were engaged in the sale of the flowers.

Western Medical College.—The Western Medical College at London, Ontario, is now the medical faculty of the Western University of that city. The following officers have recently been elected: dean, Dr. H. A. MacCallum; registrar, Dr. W. E. Waugh; executive committee, Drs. H. A. MacCallum, Waugh, Hadley Williams, H. Meek, F. P. Drake and H. W. Hill.

Personal.—Dr. J. R. Oulton, Montreal, has been appointed superintendent of the Alexandra Hospital of that city.——Dr. Murray Leys, late superintendent of the Alexandra Hospital, Montreal, has left for six months' study in Europe.——Dr. Fred Marlow, Toronto, has been appointed associate professor of gynecology in the medical faculty of the University of Toronto.

Examinations by Dominion Medical Council.—At the first examinations of the Dominion Medical Council, held in Montreal, October 7, seventy-one candidates presented themselves. Of this number forty-four passed, eight were referred to the Council, having failed on two subjects, and nineteen were rejected. Most of the successful candidates were from the provinces of Ontario and Quebec; one from New Brunswick; one each from Alberta and British Columbia; and two from the United States.

Annual Meeting Canadian Hospital Association.—The annual meeting of the Canadian Hospital Association was held in the clinic hall of the new Toronto General Hospital, October 21, 22 and 23, under the presidency of Dr. H. A. Boyce, superintendent of the Kingston General Hospital. According to Dr. W. A. Young the sale of noxious drugs has increased very rapidly the past few years in Toronto, to such an extent as to demand an amendment to the Canadian criminal code to deal with offenders. The president's address dealt with every phase of hospital and humanitarian work, and was particularly scathing of the parsimonious conduct of boards of trustees who refused to send their superintendent to the annual meetings of the association, whence they would return to their duties with renewed vigor and new ideas as to hospital work and management. The association should do all in its power to prevent the distribution of literature which makes the young think they have disease, while patent medicines containing harmful ingredients should be restricted. Dr. Boyce also advocated the standardization of hospitals and the appointment of a government architect to criticize the plans of all hospitals before they were built. Dr. Thomas Howell, president of the American Hospital Association, submitted a paper which was read by Dr. E. H. Young, assistant superintendent of the Kingston Hospital. It dealt with points for inexperienced superintendents in purchasing, receiving and distributing supplies. He advised to buy goods of good quality on the cooperative plan. By this means the hospitals could gain much. That all hospitals should share in the public taxes on the same plane, with parks and libraries, seemed to be the general approved opinion of the conference. Dr. D. M. Robertson, superintendent of the Protestant General Hospital, Ottawa, told the gathering that eight years ago a plebiscite was taken in Ottawa on the question of raising a tax for the benefit of the hospitals of that city. It carried by three to one. The tax at first was a quarter mill, then a half and now it is three quarters. In addition the hospitals in Ottawa to-day receive more private subscriptions than they ever did. Dr. J. N. E. Brown, formerly superintendent of the Toronto General Hospital, and now superintendent of the Detroit General Hospital, gave a lantern lecture on the great hospitals of the world. He seemed to be in favor of the one-story pavilions with fifty to sixty acres of land alongside of fields and woods rather than hospitals overshadowed by skyscrapers. He hoped for the day when hospitals would not be pinched in money matters. Rev. A. S. Kavanagh, superintendent of the Methodist Episcopal Hospital, Brooklyn, N. Y., dealt with indispensable combination in hospital work. The nurse leaders, he said, were committed to the policy now that the training school must stand apart from the hospital. He thought they should hail with satisfaction the divorcing of the training school from the hospital, provided it was organized on the same basis as the medical school for the young men. The trade-union spirit of the nurses was open to criticism. Dr. John A. Hornsby, Chicago, did not think there was entire disinterested cooperation in the medical staffs of the hospitals. When the practice of having medical staff officers placed on a salary and giving their whole time to their work came into vogue, blessed would be the day for the sick man or child. The failure of several Ontario hospitals refusing to retain properly qualified dispensers came in for criticism. The association elected the following officers: president, Dr. E. H. Young, Kingston; treasurer, Miss Kate Mathieson, Toronto; secretary, Dr. W. J. Dobbie, superintendent of the Weston Sanatorium for Consumptives, Toronto (reelected).

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Oct. 18, 1913.

Exclusion of Immigrants by Australia on Medical Grounds

The Australian commonwealth has issued amended and extended regulations defining those liable to exclusion as "prohibited immigrants" on account of disease. The following are so defined: (1) any person not possessed of the prescribed certificate of health; (2) any idiot, imbecile, feeble-minded person or epileptic; (3) any person suffering from pulmonary tuberculosis, trachoma or any loathsome or dangerous communicable disease, either general or local; (4) any person suffering from any disease or mental or physical defect which, in the opinion of an officer, is liable to render the person concerned a charge on the public or on any public or charitable institution; (5) any person suffering from any disease, disability or disqualification in the following list: serious deformities or physical defects; insanity, an attack of insanity within five years of proposed emigration, or a history of two or more attacks of insanity or mental derangement at any time, or dementia; chronic alcoholism; senile decay; tuberculosis of the digestive tract, or the genito-urinary system, or of bones or joints; heart-disease with signs of heart failure; chronic bronchitis with complications; paralysis or other serious nervous affections; cancer or other malignant growths; chronic rheumatism, rheumatoid arthritis or rheumatic gout, or severe hernia. The prescribed medical certificate referred to above must be obtained from approved medical referees appointed by the government.

Exclusion of Immigrants by South Africa

In South Africa a series of regulations have also been issued prohibiting from admission immigrants suffering from certain diseases. Leprosy, trachoma, favus, frambesia, syphilis and scabies are declared loathsome diseases, bringing patients with these diseases under the category of prohibited immigrants. Persons suffering from tuberculosis may be allowed to land under a permit from the immigration officer, but these permits are to be issued only at the ports of Capetown and Durban and on the following conditions: the place of residence and the mode of transport thereto to be subject to the approval of the immigration officer; the immigrant to report himself to the local health authority at his place of residence and to present himself for examination by the district surgeon or other approved medical practitioner whenever required; sleeping accommodation never to be shared with any other person, and regulations by the local health authority for preventing infection to others to be observed.

The Measurement of Mental Capacity

In a lecture delivered at University College on "Mental Energy," Spearman said that the whole of the earlier psychology, and a large part of it now, was devoted to quality of mind and not quantity. They were now turning their attention to quantity, and it was opening up a new sphere. It was possible now for every one to measure the amount of his or her mental energy. At present there was a great deal of discontent and class hatred. The lower classes complained that the upper classes obtained all the best jobs, and contended that they were quite as well equipped and that it was only their circumstances that kept them out. The upper classes, on the other hand, said that they were put there because they had more brains and were better able to do the work. But the day would come when there would be no question of persons' abilities. They would be measured to several decimal places long before they left school, and if the best positions were given to the persons with the largest amount of mental energy there could be no complaints as to other brains being more suitable.

Sir Almroth Wright on the Suffragette Movement

Sir Almroth Wright, of "opsonic" fame, has ventured into the political arena and published a book entitled "The Unexpurgated Case against Woman's Suffrage." He arraigns the whole feminist movement and bases his case on the essential inferiority of woman both intellectually and physically in comparison with man. Her claim to a vote he rejects on the ground that woman is insolvent, that is, has to be supported by man. He argues that the greater number of women who have independent incomes do not earn them but have derived them from men. He holds that nothing in the end would more certainly lead to war and revolt than the decline of the military spirit and loss of prestige which would inevitably follow if men admitted women into political copartnership. The woman voter would be pernicious to the state not only because she could not back her vote by physical force but also by reason of her intellectual defects. Women cannot recognize that the precepts of public morality are not inferior in obligation to those of egoism and domestic morality. They brush aside the ideals of abstract justice and truth in the interest of those they love. Sir Almroth Wright believes that the suffrage movement derives its impetus chiefly from offended *amour propre*. The modern girl is not taught anything about women's physical disability or the defects and limitations of the feminine mind.

The Position of Eugenics: Karl Pearson's Appeal

Karl Pearson has addressed an appeal to the *Times* on the position of eugenics as a science. He regards the current attitude of public opinion as at once disheartening and exasperating. The founder of the science, Sir Francis Galton, thought that progress toward increased race sufficiency could be made by two routes: (1) by the scientific study of heredity and environment as they bore on racial development, and (2) by a popular movement emphasizing the importance of these factors in national welfare, and the urging of their proper appreciation by legislators and social reformers. Several of those who were working on the subject differed from Galton as to the relative urgency of the two routes. They saw the danger that before the lines of the science were firmly drawn and substantial foundations laid the whole subject would be made ridiculous by the efforts of an uninstructed press to tickle the taste of a jaded public. This fear has been realized. The press now treats us to "eugenic" marriages, to "eugenic" babies, and to "eugenic" plays which have nothing whatever to do with the problem of race welfare; officials of eugenic societies submit to being interviewed with regard to well-advertised babies. Eugenics is rapidly developing into a topic for the poseur, the *Kongressbummler* and the paragraphist. Even eugenic publications and eugenic congresses are issuing statements with regard to such vitally important topics as insanity, mental defect or the influence of heredity and environment which are obviously or demonstrably incorrect. We have not yet nearly adequate knowledge on these topics. Years of patient work in medicosocial observation, in genetic experiment and in careful study of family history are needed before the laws of eugenics as a science can be dogmatically stated. When such dogmas are proclaimed in the name of eugenics as "at last it is possible to give definite advice to those about to marry or who do not wish to transmit their undesirable traits. Weakness in any trait should marry strength in that trait, and strength may marry weakness," we stand aghast at the evil worked by the rapid popularization of "eugenics" and recognize the certainty that a movement thus careless of its facts and vaunting in its conclusions must collapse. Pearson thinks that students of the science of race efficiency will be compelled more and more to drop that much-abused term and to class their work as the Germans have done, under the broad titles of race hygiene and genetics. Those who should have at heart the problem of race efficiency turn rather to the academic than the popular side of the movement. What is needed in this country, Pearson thinks, is in the first place knowledge, and this is to be obtained only by establishing in close connection with all our universities laboratories for the study of medicosocial statistics and for inquiries as to infant and child welfare, and institutes or farms for experimental breeding and for the study of experimental evolution.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Oct. 14, 1913.

Continuous Attacks of Angina Pectoris

At the Académie de médecine, which resumed its sessions October 7, Dr. Charles Fiessinger read an interesting paper on the "Prognosis and Treatment of Continuous Crises of Angina Pectoris," a subject on which the standard works generally give only vague information. These crises, which may be benign when the neuropathic element alone is the cause, on the contrary are very serious and frequently the cause of death when a renal, myocardic or aortic element is added. The fatal outcome may be avoided if care is taken to combat from the first hours the fatigue of the myocardium which these pains produce so easily. This is why one should avoid large doses of drugs. Small doses of morphin (2 mg. injections) every three hours with small doses of nitroglycerin (2 to 4 drops of alcoholic 1 per cent. solution two or three times a day) reinforced by the analgesic and tonic action of an ice-bag on the cardiac region will usually subdue the attack. A milk and water diet should be rigorously maintained, as well as absolute rest in bed. If the violence of the attack brings on cardiac failure (extrasystolic tachycardia, weakness of pulse) the use of theobromin (two powders, each 0.5 gm.) and injections of camphorated oil will ordinarily put the heart to right if the treatment with small doses of morphin and the applications of the ice-bag have been used from the first.

An Article by Paul Bourget on Professor Poncet

One of our most celebrated writers, Paul Bourget, has devoted some eloquent pages in the *Revue hebdomadaire* to the memory of Professor Poncet, whose death I mentioned in a previous letter (THE JOURNAL, Oct. 4, 1913, p. 1307). Bourget attempts to explain how this active surgeon became in his later years the pathologist to whom medicine owes the theory of tuberculous and inflammatory rheumatism—how the man of action became the man of reflection. There was always in Poncet this spirit of investigation which was not satisfied in a specialty, however brilliant it might be. This is shown by his researches on actinomycosis. But to devote himself to investigation in full maturity when circumstances and his own ability made of him without possible rivalry the first surgeon of the southeast of France—this was a most heroic resolution. Bourget believes that Poncet was impelled to take it by the legitimate and noble desire of a glory that might survive him. The destiny of great surgeons and great physicians who are only superior practitioners is somewhat pathetic in that nothing durable remains of their talent. What remains of Dupuytren, for example? An illustrious name, nothing more. Apropos of Trousseau, Lasègue, with a melancholy which he did not seek to hide, spoke of "actors, birds of passage like us." When the physician leaves behind him a discovery of permanent value in science, the case is otherwise. There were, no doubt, in the seventeenth century practitioners who surpassed William Harvey by renown and skill. Where is their work? What memory of them remains? Harvey, having discovered the laws of the circulation of the blood, is immortal. What the theory of irritation was for Broussais, that of the specificity of diseases for Bretonneau and Trousseau, that of the glands of internal secretion for Brown-Séquard, that of hysteria for Charcot, the hypothesis of inflammatory tuberculosis was for Poncet. If he has not established it definitely, he has given it sufficient standing so that even his adversaries are obliged to recognize its great importance.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Oct. 19, 1913.

Personal

October 4. Surgeon-General Dr. Zunker, for many years physician for the Empress, celebrated his seventieth birthday.

October 4, the general staff surgeon of the Prussian Army, His Excellency v. Schjerning, celebrated his sixtieth birthday. This man, who has rendered important services in the matter of military sanitation and enjoys general respect on account of his personal qualities, was the object of a cordial ovation on the occasion of his celebration. The Emperor, also, with whom v. Schjerning is in close confidential relations, gave expression in a telegram to his congratulations and to his conviction that the sanitary corps of the army under the leadership of v. Schjerning would properly fulfil its high office.

October 5, Professor Quincke, who for a number of years has been in retirement, celebrated the fiftieth anniversary of his doctorate.

Death of Kutner

Prof. Robert Kutner, director of the Kaiserin Friedrich-Haus for medical postgraduate study, died October 5 after a short illness at the age of 46, as previously mentioned. Kutner devoted himself to the development of medical postgraduate education in Germany, and inasmuch as other countries copied the organization instituted by him, he performed important service even outside of Germany. In 1901 he founded with the cooperation of the Department of Education the Prussian central committee for postgraduate medical study, the one organization which combined all of the organizations already existing in Prussia for the same purpose and had as its object the extension of free courses and exercises over the entire state. Very soon there were formed in addition to the central committee, local committees in many universities and large cities, and even the academies for practical medicine in Cologne and Düsseldorf were included. Professor v. Bergmann promptly joined the central committee and accepted the presidency (since Bergmann's death Waldeyer is president). Kutner was general secretary.

In 1902 Kutner organized an exposition of appliances to aid in medical teaching and this formed the foundation for a museum, to house which a plan for a special building was started in 1903. In view of the great interest that the Empress Frederick had exhibited in all forms of medical postgraduate instruction, the Empress-Frederick foundation for medical postgraduate instruction was formed with the cooperation of the high financial interests and the building was constructed on the Luisenplatz. It was dedicated in 1906 in the presence of the entire imperial family. It constitutes an international object of interest in medical Berlin. In addition to a large and several small auditoriums, it contains a collection of teaching materials which has meanwhile very greatly increased, a remarkable collection of antique surgical instruments and an exhibition of "The Physician and Medicine in Art," collected by Professor Holländer. It contains besides a large permanent industrial exposition with reference to medicine.

Kutner was in charge of the building which then afforded him further headquarters for his later organization of the national committee for medical postgraduate instruction, at first with Renvers and after his death with Werner Körte as president, and finally for the international committee of which Waldeyer is president, and with which all civilized nations are connected. In both of these organizations Kutner was general secretary. In this capacity a few weeks ago he was engaged at the session of the international committee in London, and immediately after his return he was taken sick.

He was born in 1867 in Uckermünde, the son of a physician, and studied in Berlin, Kiel, and Freiburg and with the urologists Nitze, in Berlin, Dittel in Vienna, and Guyon in Paris. He was licensed in 1891 and settled in Berlin in 1892 as a urologist, and did good work in his specialty. He was one of the first to succeed in taking photographic views of the interior of body cavities, and in addition to a number of minor articles and the description of instruments invented by him, he wrote a monograph entitled "The Technic and Practical Importance of Asepsis for Treatment of Urinary Affections" (Die Handhabung und praktische Bedeutung der Asepsis für die Behandlung der Harnleiden), and the text-book on "The Instrumental Treatment of Urinary Affections" (Die instrumentelle Behandlung der Harnleiden). He founded and edited also the *Zeitschrift für ärztliche Fortbildung*, the official organ of the general postgraduate work.

Loeffler Takes Charge of Berlin Institute

Professor Loeffler, the hygienist of Greifswald, has succeeded Professor Gaffky as director of the Institut für Infektions-Krankheiten. With Gaffky the institute loses a scientist of international reputation, who has performed marked service in various fields of hygiene and bacteriology. He was born Feb. 17, 1850, at Hanover, and studied as a pupil of the Kaiser Wilhelm Academy for military education in Berlin, and received a physician's license in 1875. In 1880 he was assigned to the Imperial Health Office, and here Robert Koch incited him to his pioneer work on the causes of infectious diseases. Some years later he went as a member of the cholera expedition under the leadership of Koch to Egypt and India. During this expedition Koch, as is well known, discovered the germ of cholera. Together with Koch, he made the noted report on the work of this expedition.

When Koch in 1885 assumed the newly instituted professorship of hygiene in the Berlin University, Gaffky became his successor in the health office. Soon after he was appointed professor of hygiene at the University at Giessen, and in 1892 during the cholera epidemic he gave very successful assistance as the advisor of the authorities at Hamburg, and in 1897 he headed the imperial commission sent to India for the investigation of the plague. In 1904 he succeeded Robert Koch as head of the Institute for Infectious Diseases in Berlin. Gaffky took an active part in the development and progress of modern bacteriology and made valuable contributions on disinfection, on the most important infectious diseases, on sausage and meat poisoning, etc.

Like his predecessor, Loeffler was one of the earliest colaborers with Robert Koch, and is one of the most noted of living bacteriologists. He was born June 24, 1852, at Frankfort, a. O., where his father, a prominent army surgeon later the director of the Pepiniere (an army preparatory school) in Berlin, was then a regimental surgeon. After a short period of study at Würzburg, young Loeffler attended the Kaiser-Wilhelm Academy in Berlin, and after he received his license in 1875 was first an army surgeon at Hanover and later at Potsdam.

In 1879 he received an appointment to the Imperial Health Office in Berlin where he worked at first in the chemico-hygienic laboratory under Sell and Wolffhügel. A year later Robert Koch came to the health office and asked Loeffler to undertake work in his laboratory. This change decided his later course. He took an active part in the first work performed by Koch in the Health Office on infection and disinfection, and then took up special work on immunity. In 1881 he discovered a mouse bacillus against which he was able to immunize rabbits after a single infection. After work on the germ of glanders he discovered in 1882 the diphtheria bacillus and showed methods for its recognition and cultivation and thus laid the foundation for the exact diagnosis of diphtheria and the later antitoxin treatment of Behring. In 1884 he was appointed staff surgeon to the Kaiser-Wilhelms-Akademie where he continued his work as investigator. After he joined the Berlin faculty in 1886 as privat-docent for hygiene he was called to Greifswald in 1888 as professor of hygiene. Here in the course of years he published numerous articles on bacteriology and hygiene, and many times he received commissions from the government for the special investigation of epidemics.

He applied himself chiefly to an all-round investigation of infectious diseases in animals, and among other things he paid special attention to the foot-and-mouth disease. He was president of a commission for investigation of foot-and-mouth disease, and later published a method for protective vaccination. He discovered the bacillus of swine erysipelas and of swine fever, and again made his name known throughout the world when a typhus epidemic broke out in his laboratory among the mice which proved to be dangerous only for mice. He cultivated the germ of this epidemic and by feeding the germs to mice was able to accomplish their wholesale destruction. In consequence of this, the Greek government in 1892 summoned him to Thessaly where he succeeded in suppressing a plague of mice. Loeffler has produced notable works in all fields of bacteriology and hygiene. Twice he refused a call to leave Greifswald, first to Marburg and then to the Veterinary College in Berlin. It is generally the source of great gratification that he has now accepted the call to Berlin.

Marriages

William Duncan Reid, M.D., Newton, Mass., to Miss Blanche Adeliene MacDonald of Tara, Ontario, September 23.

Valloyd Adair, M.D., Lorain, O., to Miss Mabel MacRae of St. George's Channel, N. S., at Worcester, Mass., October 6.

George William Keil, M.D., Loma Linda, Cal., to Miss Florence Heldmann of West Arlington, Md., September 10.

Wilmer Amos Hadley, M.D., League City, Tex., to Miss Sue Kathleen Kinsley, Dickinson, Tex., October 4.

Harry William Benson, M.D., Oakland, Neb., to Miss Grace M. Bohne of Rochester, N. Y., recently.

John Lafayette Gordon, M.D., to Miss Edith Henrietta Dickey, both of Columbus, O., September 24.

John Carter Rowley, M.D., Brookline, Mass., to Miss Sarah Root, Dunham, Hartford, Conn., October 11.

Emmet L. Hawkins, M.D., to Miss Vera Spetman, both of Council Bluffs, Ia., at Omaha, October 14.

Rollin G. Hendricks, M.D., Indianapolis, Ind., to Miss Grace Newcomber, Noblesville, Ind., October 15.

John Albert Konzelman, M.D., St. Louis, Mo., to Miss Bertha B. Blair, Sparta, Ill., October 16.

Noah Jefferson Goshorn, M.D., Daviess, Ind, to Miss Susie Tate, St. Charles, Mo., October 8.

Lewis J. Jones, M.D., Middlesboro, Ky., to Miss Mary Johnston, Cumberland Gap, October 16.

John S. Pyle, M.D., Toledo, O., to Miss Mary A. Raynor of New York City, *in Detroit, October* 8.

Paul A. Remington, M.D., Missoula, Mont., to Miss Jennings of Cavalier, N. Dak., October 8.

Maurice Stein, M.D., Millerstown, Pa., to Miss Sarah Rubin, Baltimore, Md., September 13.

William M. Johnson, M.D., Peckham, Okla., to Miss Hylda M. Roche, Wichita, Kan., October 15.

Ralph A. Bowdle, M.D., *to Katherine* L. Eager, M.D., both of Salt Lake City, *October* 15.

Bruno Getzlaff, M.D., Sutton, Neb., *to* Miss *Frances* Wilson of St. Louis, September 2.

Edwin Francis Jones, M.D., to Miss May Ethel Campbell, both of Barton, Vt., October 20.

Peter L. McKallagat, M.D., Lawrence, Mass., to Miss Mary Genevieve Conlon, October 14.

Isadore Michael Trace, M.D., to Miss Miriam G. Hackner, both of Chicago, October 14.

Harold M. Camp, M.D., Monmouth, Ill., to Miss Rose Laura Fox, *Chicago*, October 16.

Minerva Louise Blair, M.D., Ann Arbor, Mich., to Claude Pontius, September 22.

John Edward Dolan, M.D., to Miss *Josephine* Connell, both of Chicago, October 15.

Lowell Sidney Goin, M.D., to Miss Dawson, both of Manilla, Ia., recently.

Deaths

Joseph Lactance Archambault, M.D. Laval University, Quebec, 1870; a Fellow of the American Medical Association and once president of the Albany County Medical Society, vice-president of the Medical Society of the State of *New York*, and president of the Cohoes Society for the *Prevention of* Tuberculosis; gynecologist to the Cohoes City Hospital, and for thirty-six years choirmaster of St. Joseph's church; died at the home of his daughter in Montreal, October 16, aged 65.

Jonathan Burmond Garber, M.D. Jefferson Medical College, 1890; a Fellow of the American Medical Association, and a member of the Mississippi Valley Medical Association; a prominent practitioner of Dunkirk, Ind., *who* was crushed under his overturned automobile near Hartford City, *September* 30, died in *Hartford* City, October 3, from his injuries, *aged* 57.

George Drury, M.D. Long Island College Hospital, Brooklyn, N. Y., 1878; a member of the Medical Society of *the* state of New York, and for thirty-five years a practitioner of Brooklyn; died in the Skene Sanatorium, Brooklyn, October 20, following an operation for disease of the intestines, aged 56.

Sylvester Rush Weaver, M.D. Vanderbilt University, Nashville, Tenn., 1894; a Fellow of the American Medical Association, and a specialist on diseases of the eye, ear, nose and throat of Sherman, Texas; aged 41; died at his home in that city, September 24, *from carcinoma* of the stomach, for which he had undergone operation several months before.

Albert Harrison Moore, M.D. Jefferson Medical College, 1896; a Fellow of the American Medical Association; mayor of Ashland, Ky.; local surgeon of the Chesapeake and Ohio System; formerly coroner of Boyd County; one of the most prominent practitioners of northeastern Kentucky; died at his home in Ashland, September 26, aged 42.

George Summers Brown, M.D. Jefferson Medical College, 1895; *a member of the* Medical Association of the State of Alabama and Southern Surgical and Gynecological Society; a leading surgeon of *Birmingham; died in* Lakeside Hospital, Cleveland, O., September 28, after an operation for the removal of gall-stones, aged 53.

Arthur Adelbert Downs, M.D. Baltimore Medical College, 1897; a Fellow of the American Medical Association, and the National Antituberculosis Society; who was instrumental in the establishment of the Chase Sanatorium, Fairfield, Maine; died at St. Barnabas' Hospital, Portland, October 13, from septicemia, aged 39.

***Thomas Alexander Elder,* M.D.** Rush Medical College, 1868; Bellevue Hospital Medical College, 1872; a member of the Ohio State Medical Association; a veteran of the Civil War and one of the oldest practitioners of Wooster; died in the Presbyterian Hospital, Chicago, October 19, from heart disease, aged 70.

George Turner Hesser, M.D. Cooper Medical College, San Francisco, 1895; a Fellow of the American Medical Association; local surgeon of the *Southern Pacific System at* Folsom City, Cal.; died in St. Francis Hospital, San Francisco, September 22, after an operation on an infected gall-bladder, aged 50.

William John Bradley, M.D. Rush Medical College, 1890; a Fellow of the American Medical Association, and a member of the staff of St. Luke's Hospital, Cedar Rapids, Ia.; one of the ablest and best-known *practitioners of* Cedar *Rapids;* died in St. Luke's Hospital, October 2, from typhoid fever, aged 47.

Reuben E. Brokaw, M.D. Western *Reserve* University, Cleveland, 1895; a Fellow of the American Medical Association; died at his home in Portland, Ind., July 26, from acute general streptococcus infection, aged 45.

Francis Loring Banfield, M.D. Bowdoin Medical College, Brunswick, Me., 1881; a Fellow of the American Medical Association; died at his home in Worcester, Mass., June 25, from angina pectoris, aged 69.

Arthur Scott Koenig, M.D. University of Pennsylvania, *Philadelphia*, 1901; a Fellow of the American Medical Association and a practitioner of Lewistown, Pa.; died in Philadelphia, about September 21.

Edwin C. Reames, M.D. University of Buffalo, N. Y., 1895; a member of the Medical Society of the State of New York; died at his home in Canastota, September 25, from nephritis, aged 43.

Henry H. Havens, M.D. Medical College of Ohio, Cincinnati, 1880; a member of the Ohio State Medical Association; died at his home in *Tippecanoe* City, O., from erysipelas, aged 56.

William Cecil Stafford, M.D. Detroit (Mich.) Medical College, 1872; for twenty-five years a practitioner of Youngstown, Ohio, died at his home, September 14, aged 66.

Frank P. Witham (License, years of practice, Ohio, 1896); *for* thirty-five years a practitioner of Withamsville, *O.; died* at his home, September 29, aged 60.

Walter Z. Twitchell (license, Maine, 1895); for *twenty-five* years a practitioner of Andover, Maine; *died at his home in* that city, September 13, aged 58.

Ezra E. Tope, M.D. Starling Medical College, Columbus, Ohio, 1880; died at his home in Scio, Ohio, from sarcoma, August 17, aged 62.

R. N. Taylor, M.D. Chattanooga (Tenn.) Medical College, 1901; of *Chattanooga;* died in a sanatorium in *that* city September 2.

William G. Todd, M.D. Rush Medical College, 1844; of Chicago; died *at* the home of his daughter *in that city, August* 7, aged 91.

Thomas L. Williams, M.D. University *of* Louisville, Ky., 1869; *died at* his home in Pulaski, Tenn., September 18, aged 81.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

MEDICAL JOURNALS AND THE GREAT AMERICAN FRAUD

The responsibility of medical journals for the continued existence of at least a part of the "great American fraud," has been referred to in these pages many times. Within the past few weeks The Journal has called attention to the inconsistency of reputable physicians of high ideals lending their moral, and often financial, support to those medical journals whose advertising pages are a disgrace to the profession. Specifically, the *Medical Times*—originally a homeopathic medical journal—has been referred to, among others, as an example of this type of journalism. It must, however, be regarded simply as a type, for it is no better and no worse than many other medical journals. Several letters have been received on the subject, some of which we reproduce. The first one is from Dr. George G. Ross of Philadelphia:

> "I was very much jarred on receiving the last issue of The Journal to find under the Propaganda for Reform an article concerning the *Medical Times*, among the list of whose contributing editors my name appears. I enclose you herewith a copy of my letter of resignation to the *Medical Times*. I have a very dim recollection of what occurred at the time that I was asked to give my name as a contributing editor. As I recollect it, however, at that time the journal was a respectable and ethical publication. I had been asked by a friend of mine to write an article giving my opinion of the effects of college athletics on undergraduates. This was at the time that Dr. Stokes had issued his order about athletics at Annapolis. I want personally to thank you and the committee for the exposure of this journal and for having drawn my attention to the fact that I was unwittingly aiding and abetting such a journal. I trust that if you have space in some future number of The Journal, you will do me the justice to publish all or part of this letter."

Because he feels that he has "unwittingly been put in an unfavorable light," Dr. James A. Babbitt, also of Philadelphia, sends The Journal a copy of a letter written by him to the editor of the *Medical Times*. Here it is:

> "For reasons of which you are probably cognizant, I deem it advisable to resign from the board of contributing editors of the *Medical Times*, and desire that this resignation be accepted at once and my name not appear in further issues."

What shall be done, asks Dr. Sidney Thompson of Humboldt, Tennessee, in such cases as the following? Says Dr. Thompson:

> "In the Propaganda for Reform, in The Journal, October 18, 1913, in closing your article on 'Medical Journals and the Great American Fraud,' you say: 'The physician who permits such journals to come to his office must share with the paid subscribers the responsibility for the low standard of medical journalism.' Now I agree with you in everything you have said about the *Medical Times*, but what I want to know is how to keep such journals from coming into your office. The *Medical Times* has been coming to me for a number of years with repeated duns for the subscription price. I have written to them several times that I did not want the journal and never expected to pay for it, but still it comes. I have a vague recollection that I bit *at an offer* to send it three or four months free, not knowing what it was, but I never authorized them to enter my name as a regular subscriber."

The simplest course in such a case as that described by Dr. Thompson, is to write *on the* unwelcome publication the word "refused" and either drop it in the nearest mail-box or hand it back to the postman. The courts have held that a person who continues to accept publications is legally liable for the payment of such publications. The postoffice department, however, has ruled that a magazine—either monthly or weekly—may not be sent at second-class rates for more than one year after the expiration of a bona fide subscription. At the expiration of that time, stamps must be affixed and the publications sent at third-class postal rates.

SOME DEAFNESS-CURE FRAUDS

The name of the deafness-cure quack is legion. Some carry an alleged cure for deafness as a "side-line" for other medical fakes they may be exploiting; some sell on the mail-order plan a worthless "course of treatment," while still others, and these probably are in the majority, dispose of, at an exorbitant price, devices that are trivial, worthless, and often dangerous. Many of the American deafness-cure quacks do an international business. Particularly do they invade that verdant field for medical fakers, the British Isles. Some of the most blatant of these have been exposed on the other side by Evan Yellon, editor of the *Albion Magazine*, a publication issued in the interests of the deaf. Mr. Yellon is a journalist of the militant type. Himself a sufferer from deafness, he appreciates the viciousness of the victimization carried on by the deafness-cure quacks. While a layman, Mr. Yellon expresses himself with no uncertainty regarding the dangers of quackery. Says he:

> "There is the very world of distinction between the qualified specialist and the quack. In one case you have a man . . . whose special education and training will have required the sinking of a round sum in capital plus many years of life . . .
>
> "On the other hand, in the quack, we have in the majority of cases a man who does not possess even a sound general education, and who very often does not understand the elements of ordinary personal cleanliness. . . . He is a man moving in the dark, and thus making only blind shots . . . He is a man of mysterious methods and secret remedies, and his vogue to-day is at once a significant token, and, as I have said, a menace to the community."

These words, while written for British readers, apply with equal truth and equal force to the American fakers who sell deafness "cures."

The following paragraphs have been written for the purpose of making more complete a pamphlet,[1] we have in preparation especially for the enlightenment of the public on the subject with which it deals. The numerous inquiries that have been received during the past three or four years regarding the concerns specifically dealt with in the matter that follows is The Journal's excuse for publishing it here.

"Dr. L. C. Grains Company" née "Dr. Guy Clifford Powell"

Dr. Guy Clifford Powell, the deafness-cure quack of Peoria, Ill., was dealt with at some length by Mr. Adams in the "Great American Fraud" series. Powell's particular fake was what he called the "Electro-Vibratory Cure for Deafness," for which he asked $100 in his first letter to prospective victims, but—sliding swiftly through a series of form letters—finally offered to take $15 if the quarry seemed in any danger of escaping. As Mr. Adams said, Powell's Cure "isn't worth $100 or $30 or $25 or 25 cents, except as its patent right owned by the 'discoverer' is an asset in his swindling operations." Powell called himself an "International Specialist"; if he had said international quack, he would have been correct, for he advertised heavily on both sides of the Atlantic.

In due time, Powell went the way of all flesh, but his fraudulent business was too valuable an asset, apparently, to let die. It is now being carried on by a concern known as the "Dr. L. C. Grains Company," and is operated from Chicago instead of Peoria. The Dr. L. C. Grains Company is said to have the following officers:

Floyd R. Perkins, president.
J. Howard Start, vice-president.
George H. Ely, secretary and treasurer.

---

[1] "Deafness-Cure Frauds," price 10 cents.

None of these gentlemen, it seems, are physicians or are even remotely connected with medicine or pharmacy. They are, as is so often the case in quack concerns, advertising men and operate an advertising agency—the Charles H. Fuller Co., Chicago. According to the Chicago City Directory, Messrs. Perkins, Start and Ely hold the same official positions in the Charles H. Fuller Company that they hold in the Dr. L. C. Grains Company.

L. C. Grains seems originally to have had a small mail-order fakery of his own. "Red Clover Extract" and "Curo Grains of Life" were his specialties. After the officers of the Charles H. Fuller Company bought out the Powell factory and moved it, bag and baggage, from Peoria to Chicago, L. C. Grains had the title "Dr." added to the concern. So far as our records show, and they are exceedingly complete, L. C. Grains has absolutely no claim to the title of doctor of medicine.

DEAFNESS CURE
DR GUY CLIFFORD POWELL
Deafness Cure
DIAGNOSIS BLANK

Fig. 1.—Photographic reproduction of some of the old advertising put out by Dr. Guy Clifford Powell. It is used practically in its entirety by the Dr. L. C. Grains Co., successors to Powell's fakery. Compare it with Figure 2.

The advertising matter, booklets, leaflets and the general paraphernalia of the mail-order medical fake issued by the Dr. L. C. Grains Company is practically identical with that used by Powell. About the only changes that have been made are those of substituting the words "Dr. L. C. Grains Company" for "Dr. Guy Clifford Powell." The "International Specialist" has become the "International Specialists." So far as we have been able to discover the only physician connected with the Dr. L. C. Grains Company is one R. C. McFall. The records show that a woman of that name was graduated by the, since, defunct Indiana Eclectic Medical College in 1888. Dr. McFall seems to have practiced for some years in Indianapolis. Since 1900, however, she has been in Illinois, most of the time, apparently, in Chicago. For an "international specialist," she seems to be little known. Needless to say, Dr. McFall is not a member of the Chicago Medical Society.

In brief, the Dr. L. C. Grains Company, which derives its profits from the unfortunate deaf, is a fraud as was its predecessor, the Guy Clifford Powell concern.

Edward E. Gardner

Dr. Edward E. Gardner is in the "deafness-cure" business at 38 West Thirty-Third Street, New York City. In his advertisement he calls himself "a celebrated New York Aurist"; a notorious New York quack would be nearer the truth. Gardner says, speaking impersonally of himself:

> "His diploma is endorsed and he is given the honor to practice medicine not only in New York State but by searching tests and thorough examination is given endorsement by the State Boards of New York, Pennsylvania, Illinois, Massachusetts, Vermont, and, in fact, all the states and territories in the United States. He is also allowed to send his treatment to England, Scotland, Ireland, France, Germany, Italy, and to all parts of the globe. Very few doctors have had this distinction bestowed on them. This means that you can rely on his treatment."

As lying is the chief stock-in-trade of quackery, Gardner ought to be highly successful in his chosen calling, for it would be hard to condense into smaller space than the matter just quoted a greater number of direct and inferential falsehoods.

In 1890 Gardner seems to have been practicing in the state of Illinois and Pennsylvania, but soon thereafter is alleged to have been connected with the Copeland Medical Institute at Fifth Avenue, New York City. About 1900 he and his father-in-law are said to have opened an office on West Thirty-Fourth Street, New York City, where he exploited a "catarrh cure" under the name of the Norma Medical Association. Still later, he moved to his present address where he and his brother, E. A. Gardner—who is not a physician—conducted business under the style "Drs. Gardner" until official intervention caused a change in title to "Dr. Gardner."

Gardner was a stockholder in the "Help-to-Hear Company," a cruel swindle put out of business by the federal authorities in 1906. In 1907 Gardner went into bankruptcy with about $13,000 liabilities and no available assets. The Norwich Pharmacal Company is said to have been one of his largest creditors.

Gardner's methods are typical of the mail-order quack: Letters, a sliding scale of prices and the other stock-in-trade of the ilk. Like all mail-order fakers, Gardner disposes at intervals of the letters he receives from victims. A letter-broker concern in New York City has advertised over 12,000 of Dr. E. E. Gardner's "deaf letters" for sale or rent. Those who write Gardner are sent a "free trial treatment" consisting of a small amount of ointment to put into the nostrils, some solution to drop in the ear and some tablets to take internally. The "regular treatment," we are told, costs $5 and lasts one month. This price he keeps up for three or four letters and then cuts it to $2.60. Some time later he writes again, making a "special rate" of $3 for a month's "treatment." He guarantees "to bring good results in three months," which "at $3 a month would be $9." He offers to cut this in two and to send a three months' treatment for $4.50 and says: "Now I think this is a grand offer, I think one that you ought to accept." With this letter he encloses a slip describing other "cures" that he handles as side-lines. His "special rheumatism treatment including medicines" comes at a dollar a month; constipation he will handle at 50 cents a month; insomnia costs a dollar, as do also hysteria, indigestion and blackheads. Taking it all in all, Gardner seems to fulfil all of the traditions of quackery. The deaf cannot do better than avoid him.

George P. Way Ear-Drum

George P. Way does business from Detroit, Mich. He sells what he calls a medicated ear-drum which—if we are to believe the advertising matter—is so wonderful that it enables a man who is so deaf that he cannot hear thunder to hear a clock tick thirty feet away! But, of course, we are not to believe what George P. Way publishes. Way claims to have cured himself of twenty-five years' deafness by means of his drums. He asks $5 a pair for them, but if you are not too anxious you will receive the usual follow-up letters and before long will be able to purchase not only a pair of ear-drums but also "a very unique instrument" that Mr. Way has christened "Blowena"—all for $5. Blowena is a "catarrh cure" which George P. sells as a side-line to his ear-drum offer.

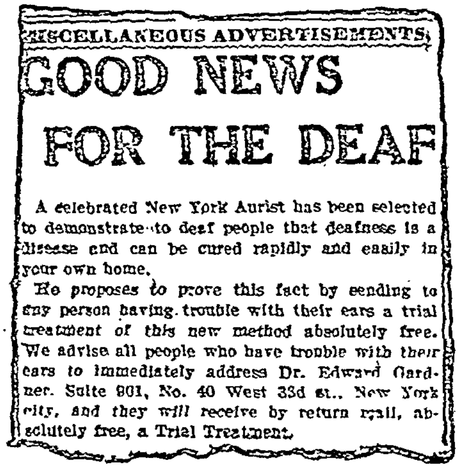
A study of the advertising matter that he has sent out during the past few years shows various discrepancies in the statements made at different times. In one of his earlier leaflets Way, who claims to have been an engineer, declares that before he "discovered" and "invented" his ear-drum he was so deaf that "it was with difficulty that I could hear the noises of my own engine." The later leaflet omits the sentence just quoted although the balance of the matter is practically identical. Why? Was the falsehood too raw, even as an asset to quackery? In the earlier leaflet, he said:

> "*I* have been granted patents in *all* foreign countries as well as in the United States."—[Italics ours.—Ed.]

More recently, this has been toned down to:

> "Patents have been granted in foreign countries as well as in the United States."

This modification is explainable to those who look into the matter carefully. In the first place, it is *not* true that Way ever was granted patents "in all foreign countries"; in the second place, the elimination of the personal pronoun is doubtless due to the fact that the "medicated ear-drum" that Way sells is not his invention but the invention of Frances M. Way, his wife! Incidentally, Frances M. Way *is* the individual referred to in the advertising *matter thus:*



MISCELLANEOUS ADVERTISEMENTS

GOOD NEWS FOR THE DEAF

A celebrated New York Aurist has been selected to demonstrate to deaf people that deafness is a disease and can be cured rapidly and easily in your own home.

He *proposes to* prove this fact by sending to any person having trouble with their ears a trial treatment of *this* new method absolutely free. We advise all people who have trouble with *their* ears *to* immediately address Dr. Edward Gardner, Suite 901, No. 40 West 33d st., New York city, and *they will* receive by return mail, absolutely free, a Trial Treatment.

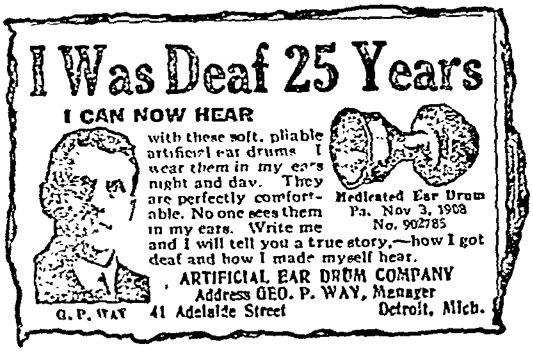
Fig. 3.—An advertisement of Quack Gardner in which he describes himself as "a celebrated New York Aurist."

> "Most important of all, I have with me Dr. F. M. Way, who is a well-known specialist of the ear, nose and throat . . ."

It is hardly necessary to say that Dr. Way is not a "*well-known specialist*"; actually she was graduated in 1902 by the *Detroit Homeopathic College*, a low-grade institution now defunct.

Way publishes comparatively few testimonials, for a quack. Although we have a full set of his *follow-up letters*, covering a period of some years, there are less than a dozen testimonials all told. Yet, Mr. Way claims that he has hundreds on *file! One* testimonial that he has featured *to the extent* of publishing not only a fulsome letter but *a photograph* of the person giving it came from a young woman who, the public was told, "was so deaf *that I* was attending a deaf-*and-dumb school.*" She bought a pair of Way's ear-drums, and "*now* can *hear a clock* tick in any part of the room." A physician was written to who lives *in the same* town as this young woman. He declares *that the girl* has never been extremely deaf and her hearing is not yet restored.

The Way "medicated ear-drum" itself *is a* particularly vicious little device. While there is *nothing in the advertising* matter sent out by Way to make this clear, it is a fact that the drums are specially designed for individuals whose tympanic membrane ("ear-drum") is ruptured. It is a rubber contrivance enlarged at each end and with a constricted portion in the center. One of the enlarged ends is supposed to be pushed into the middle ear. The drums are recommended for discharging ears; actually they are about the worst things that could be used *in such a condition.* The amount of damage a piece of fakery of this kind can do is almost beyond belief. But it furnishes the Way family an income which they are willing to divide with those publications that are not above participating in the profits of quackery.



I Was Deaf 25 Years

I CAN NOW HEAR

with these soft, pliable artificial ear drums I wear them in my ears night and day. They are perfectly comfortable. No one sees them in my ears. Write me and I will tell you a true story,—how I got deaf and how I made myself hear.

Medicated Ear Drum
Pa. Nov 3, 1908

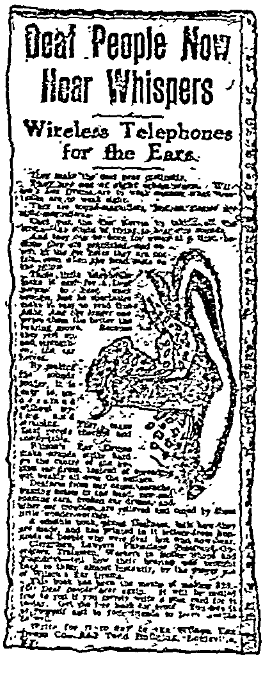
ARTIFICIAL EAR DRUM COMPANY
Address GEO. P. WAY, Manager
41 Adelaide Street Detroit, Mich.

Fig. 4.—George P. Way's advertisement. The Way Ear-Drum never cured a case of deafness but might easily prove a serious injury to the deaf.

The Wilson Ear Drum

The Wilson Ear-Drum, exploited by George H. Wilson, Louisville, Ky., is another of the small rubber contrivances, made to slip into the external auditory canal (the outer ear-passage), of which there are so many *on* the *market.* It is advertised under the usual fraudulent claims and is just as worthless as most devices of this sort and just as potent for harm. One might imagine that plain business judgment would prevent Wilson making claims that every person who has reached the age of *accountability,* whether he is technically educated or not, would be able to recognize as evident falsehoods. In the world of quackery, however, no such restrictions seem to hold. As Mr. Adams has so well remarked: "Our national quality of commercial shrewdness *fails* us when we go into the open *market* to purchase relief from suffering." Otherwise no quack could make such claims as Wilson makes and "get away with them." Here, for instance, is what is claimed for the Wilson Ear-Drum:

> "It is the only device in the world that collects sound waves and *focuses* them to one point.'
>
> "It is the only device in the world constructed on scientific principles."
>
> "It is the only device in the world that is made to fit the orifice of the ear."
>
> "It is the only device in the world that cannot possibly injure the hearing."



Deaf People Now Hear Whispers

Wireless Telephones for the Ears.

Fig. 5.—A Wilson Ear-Drum advertisement. These worthless little rubber devices are described as "wireless telephones."

These are only a few of the superlative virtues assigned by Mr. Wilson to his trumpery piece of rubber. Elsewhere he calls them "wireless telephones for the ears," and claims that by their use "every condition of deafness or defective hearing is being helped and cured . . ."

Wilson sells his ear-drums on the mail-order plan; also he travels over the country selling them. In some of his advertising Wilson claims to have been president of the Louisville School Board. This will not surprise those familiar with the exploitation of medical frauds who know that the second largest city in the United States until recently had for its president of the Board of Education an individual who made his money out of the sale of a "cure" for sore eyes and a correspondence school of spectacle fitting. Wilson also claims to have been "honored with the presidency of the Kentucky Society Sons of the American Revolution," which, while doubtless a splendid advertising asset for Wilson, does not do credit to the judgment of a presumably reputable organization.

The Wilson Ear-Drum, with "nickel forceps" and "drum inserters" thrown in, come at $5 a pair. As cures for deafness they are not worth five cents, except as they presumably furnish Wilson with an easy living.

THE CANADIAN REPORT ON THE FRIEDMANN "CURE"

Reference has been made to the action of the Canadian authorities on the Friedmann "cure," but the report has not heretofore been given in full. Here it is:

"In order to allay public excitement and to afford to the medical profession and people of Canada an authoritative statement regarding the value of Dr. Friedmann's treatment, the Canadian Association for the Prevention of Tuberculosis nominated a committee of five members to study and report on the cases inoculated by Dr. Friedmann at Montreal, Ottawa, Toronto, and London, Ontario. That committee has added to itself those physicians who have under observation the cases treated in these cities. The committee thus constituted begs to report that it has carefully studied the case histories of the patients inoculated by Dr. Friedmann. These number altogether 161, namely, for Montreal 55, for Ottawa 10, for Toronto 81, for London 15.

"As a result of our observations from March 11 to June 23, the following conclusions seem justifiable:

"1. The inoculations have neither constantly nor frequently been followed by any marked change in the clinical course of the disease.

"2. The cure or progress toward cure claimed by Dr. Friedmann for his treatment has neither constantly nor even frequently taken place in the time during which these cases have been under observation.

"3. Thus on investigation the committee finds that the results have been disappointing, and that the claims made for this remedy have not been proved, and that *nothing has been found to justify any confidence in the remedy.*" [Italics ours.—Ed.]

Correspondence

Preliminary Report of a Case of Sensitization to the May-Fly (Ephemera)

To the Editor:—In July, 1913, a patient consulted me for attacks of a distressing coryza with sneezing, lacrimation and a reddening of the eyes. He stated that these attacks came on during June and July and appeared to be brought about while driving in the evening whenever he encountered a swarm of those ephemerids commonly called "May-flies," "Canada soldiers," "fish-flies," etc. These insects, as is well known, are abundant in the region of the Great Lakes, the imago passing its brief existence in the air, at which time the female is fertilized. The attacks from which the patient suffered had begun a few years previously and without assignable cause. The symptoms were quite like those of hay-fever without asthma, and after each one, in the absence of a repetition of the usual exciting cause, a day or two was necessary for recovery.

In order to test the hypothesis of a sensitization to the ephemerid, a single insect was caught and shaken in a vial with about 2 c.c. of sterile saline solution. One drop of this solution was placed in the patient's right eye. In less than two minutes there was smarting and irritation of the eye, and within fifteen or twenty minutes a marked conjunctival redness and a pronounced chemosis developed, the other eye remaining normal. Three controls were tried with the same solution on presumably normal subjects with negative results. The reaction in the patient's eye from the experiment was so great, and was attended with so much physical distress for from twenty-four to twenty-six hours, that no subsequent experiments have been attempted; but I have in preparation some protein extractives from the dried insects, which may make further investigation possible, and I hope to make a later report in the matter. Whether the sensitizing agent of the ephemerid is a substance generally distributed through its body, or resides in the eggs, which are abundant, or in some other special organ or part is not yet clear.

I supposed that this peculiar form of sensitization had not been noted or reported by any other observer and was surprised to learn by personal communication from Mr. F. West of the Gratwick Laboratory in Buffalo that a similar case has been observed this year by Dr. F. W. Hinckel of that city.

If any cases of sensitization to this ephemerid have been recognized by others, I should be gratified for any information concerning them.

Harold Wilson, M.D.,
32 Adams Avenue West, Detroit.

Sterilization of Rubber Gloves by Boiling

To the Editor:—The method of sterilizing rubber gloves described by Dr. Ray Ernest Smith in The Journal, Oct. 18, 1913, p. 1475, is a good one when only one examination of the patient is required. I, however, prefer to boil them. I know then that they are absolutely safe. I put the gloves into a small pan of water, place it on an ordinary kitchen or oil stove, and let them boil a few minutes. This I do while I scrub my hands and arms with soap and water, using no antiseptic whatever. I allow cold water to run into the gloves to dislodge the hot, and draw them on while they are distended. After each examination I put the gloves back into the hot water and give them another boil. Frequent boiling of rubber gloves does not impair their quality if they are not roughly handled and if thoroughly dried after using. I believe that this is the safest, simplest and most satisfactory method of sterilizing gloves for obstetric work.

Walter A. Landry, M.D., Chester, Pa.

Exuberant Verbosity

To the Editor:—Has the editorial writer (The Journal, Oct. 18, 1913, p. 1464) overlooked the historical fact that the exuberant verbosity of legal forms was not an intoxication, but a species of graft? Old English law-clerks were paid so much a word or a line for engrossing legal documents, and in consequence the more words used, the greater the pay. Every synonym, nearly or distantly connected, was drawn in and duly inscribed. A sentence lingers in my memory, taken from an old English common-law form of indictment for maintaining a nuisance in which it is alleged that "divers odors, savors, smells, scents and stenches did issue, proceed and flow therefrom." As the principles of *lex scripta* are said to be immutable, so also appears to be its language; for the same quaint, archaic phraseology, scarcely altered except in spelling, is used in legal forms to-day as in the days of Good Queen Bess or in those of Bloody Mary.

Bernard Wolff, M.D., Atlanta, Ga.

Tuberculosis Among Schoolteachers.—Over a period of years 52.4 per cent. of the deaths among schoolteachers, between the ages of 25 and 34 were due to tuberculosis, while only 25.8 per cent. of the deaths among all persons in Michigan, between the ages of 25 and 34, were due to this disease. Among schoolteachers of all ages 27.6 per cent. of the deaths were due to tuberculosis, while among all persons of all ages only 9.4 per cent. were due to this disease.—*Bull. Mich. State Bd. Health.*

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

OPEN-AIR TREATMENT AND THE FLUELESS HEATER

To the Editor:—By an appropriate coincidence two editorials in The Journal of October 11 give the two sides of the theories of ventilation. The "Open-Air Treatment" editorial outlines the newer ideas, while the "Flueless Heater" represents the older teaching, that air may become vitiated and contaminated.

The teachers of the new philosophy authoritatively assume and proclaim that from their interpretation of a few experiments which they have made we can safely disregard any accumulation of carbon dioxid which may occur; that body exhalations or odors are of no ill effect, or if any effect is supposed to be produced, it is purely psychic; that the oxygen content cannot be decreased in an overcrowded room to cause any ill effect, but that the ill effects which do occur in crowded rooms are due to stagnation of air with high temperature and humidity, which disturb the heat balance of the body, and that all ill effects of overcrowding may be relieved by agitating the air to break up the air envelope of the body.

These conclusions which are so authoritatively proclaimed are based on a few laboratory experiments, altogether too few to permit definite conclusions to be safely drawn on a subject which concerns the health of millions of people.

The subject of an experiment carried on for a few hours in a laboratory may not be conscious of any ill effects. There may be no ill effects so far as he is concerned because of the wonderful adaptability of the human body to its environment; but to say that under similar conditions the millions of people in shop and factory would suffer no ill effects is an unwarranted conclusion.

The resistance of the human body may be perfect in an experiment of a few hours, but when it is exposed to the same conditions for months and years, the accumulating effect will result in deterioration of health and increase of disease and death.

The logical conclusion from this new idea of ventilation must result in a lowering of the standards of air purity and an indifference in the public mind to the need of any effort for efficient ventilation.

We should not be hasty to draw conclusions from insufficient evidence. Let the investigators gather and present their facts. The experimenters may lack the judicial temperament to properly interpret the facts which they gather. The subject of ventilation is still open and more facts should be observed and presented for consideration before we can draw definite conclusions.

John B. Todd, M.D., Syracuse, N. Y.

Answer.—Our correspondent is evidently unfamiliar with the literature when he declares that the laboratory experiments made on this matter are too few to warrant definite conclusions. We would refer him especially to the following articles:

Heymann: Ztschr. f. Hyg., 1905, xlix, 388.
Paul: Ibid., 1905, xlix, 405.
Erclentz: Ibid., 1905, xlix, 433.
Flügge: Ibid., 1905, xlix, 363.
Reichenbach and Heymann: Ibid., 1907, lvii, 23.
Hill, Rowland and Walker: *Jour. Physiol.*, 1911, xli,

References to a number of other articles dealing with the alleged toxic properties of expired air, together with a full discussion of the question, are given in an excellent article by Crowder (*Arch. Int. Med.*, January, 1911, p. 85; abstr., The Journal, Feb. 25, 1911, p. 622). The question of what constitutes "sufficient evidence" is always more or less a matter of personal experience in dealing with the question under consideration, and is always influenced temperamentally by the ease with which long-cherished beliefs can be abandoned.

There is no contradiction or inconsistency between the two editorials referred to. The oil- or gas-heater, in the very nature of the case, makes it essential that the windows and doors be closed if it is to produce the effect desired—that of raising the temperature. If it has no flue, then it means not only that the oxygen is consumed, with a corresponding amount of carbon dioxid produced, but, what is of much greater importance, if there is much imperfect combustion carbon monoxid, a definite active poison, is poured forth into the room.

TRYPSOGEN

To the Editor:—Can you tell me anything of the G. W. Carnrick Company, manufacturing chemists, New York? Do you know anything of their product Trypsogen for treatment of diabetes mellitus?

W. D. Casey, M.D., Walls, Miss.

Answer.—Besides exploiting a clay poultice—"Antithermoline"—the G. W. Carnrick Company appears to be chiefly concerned in the promotion of "internal secretion" specialties; a class of preparations the therapeutic value of which is problematical. Thus it markets the diabetes remedy, "Trypsogen" tablets, said to contain "the enzyme of the islands of Langerhans with the tryptic and amylolytic ferments of the pancreas" along with gold bromid and arsenic bromid; Secretogen Elixir, said to be "prepared from gastric secretin obtained from the pyloric antrum and pancreatic secretin from the duodenum, combined with the enzymes of the peptic glands, and one-twentieth of one per cent. HCl"; Secretogen Tablets, said to be "prepared from prosecretin and succus entericus obtained from the epithelial cells of the duodenum, combined with pancreatic extract"; Kinazyme, "a preparation of extract of spleen, reinforced with trypsin, amylopsin and calcium lactate."

While great claims have been made for Trypsogen and while it has been most widely advertised, it is the consensus of opinion of the most eminent students of the question that pancreas is not really efficacious in diabetes. Were it of any value in this disease, it would have won world-wide recognition for itself ere now, in view of the great enthusiasm with which the discovery of the relation of the pancreas to diabetes was received and of the enormous amount of clinical, as well as animal, experimentation that followed. As the conditions of experiment in this question are extremely complex, it is not surprising that occasionally apparently positive results should have been obtained. Were it really useful, it should have yielded positive results much more uniformly.

Furthermore, if pancreas were really efficacious in the treatment of diabetes mellitus, the addition of arsenic, of gold, of bromid would be entirely unnecessary.

Even were it granted that pancreas extracts are valuable in the treatment of diabetes, and that gold and arsenic also have beneficial effects, it is our opinion that Trypsogen should be considered an unscientific shotgun mixture, because fixed combinations of remedies of different potencies, such as arsenic, gold, bromid and pancreas, are therapeutically erroneous, as they do not permit of that accurate adjustment of dosage of each ingredient that is indispensable to obtain maximum benefit with minimum danger of poisoning.

Antithermoline and Trypsogen were at one time described in New and Nonofficial Remedies. These preparations were omitted when the Council's rules were revised some years ago.

When the Council was first organized it undertook only the correction of the most serious abuses that had become a part of the proprietary medicine business, and paid less attention to the therapeutic worth of a remedy; thus at that time it admitted both Antithermoline and Trypsogen to New and Nonofficial Remedies. Since then the Council has modified its rules to exclude unscientific mixtures marketed under names that are misleading or therapeutically suggestive. Accordingly it rescinded the acceptance of Antithermoline, which was essentially the official clay poultice, Cataplasma Kaolini, U. S. P. For similar reasons and because the therapeutic claims were held unwarranted Trypsogen has been omitted from New and Nonofficial Remedies.

It is to be regretted that the progress of research should be hindered and the value of genuine products of internal secretion be depreciated by confusion with such shotgun mixtures and asserted remedies, whose claims have received no scientific confirmation.

RADIO-ACTIVITY OF SPRINGS

To the Editor:—I should like to know the radio-activity of the different American and foreign radio-active springs as compared with the radio-activity of sea-water, particularly the water of the North Atlantic.

D. T. Quigley, M.D., North Platte, Neb.

Answer.—All naturally occurring waters, even rain-water, are somewhat radio-active; few figures, however, are available as to the degree of this radio-activity in the case of American waters. Schlundt (*Tr. Wisconsin Acad. Sc.*, 1910) reported the activity of the water of a well at Madison, Wis., to be 1.9×10^{-10} curies per liter (expressed in the international unit); that of certain springs in Wisconsin was two or three times as great. Schlundt and Moore (Bull. 395, U. S. Geological Survey) found the radio-activity of various springs in the Yellowstone Park to range from 0.2, or less, to 24×10^{-10} curies per liter. Lazarus (Handbuch des Radiums in Biologie und Therapie) states that the Gastein springs range from 116 to 524×10^{-10} curies; one spring at Johannisthal had an activity of 2,220.

Probably the most complete investigation of any American springs was that of Boltwood, in connection with the Hot Springs of Arkansas; the results, however, have never been made public. Some time ago The Journal wrote to the Secretary of the Interior requesting information on this subject. The department replied that "For administrative reasons this report was not published in its entirety," the only official statement being that the waters "are radio-active to a marked degree"—a statement which might have emanated from a patent medicine manufacturer. From statements made by Boltwood (*Am. Jour. Sc.*, 1905) and by Schlundt and Moore, it would seem that the water of at least one spring at Hot Springs has an activity of over 100 × 10^{-10} curies per liter. It would be interesting to know what the "administrative reasons" are which have prevented the publication of the whole truth concerning Hot Springs.

DRUGS WITH THERAPEUTICALLY SUGGESTIVE NAMES

To the Editor:—The following is the copy of a label on one of Merrell's bottles found by me at the company store at Berryburg:

100 PILLS GONORRHEA, 3 GRAINS

Pulv. Cubeos	1¼ gr.
Solid Copaiba	1¼ gr.
Sulph. Iron Exsic.	¼ gr.
Venice Turp.	¼ gr.

Dose 1 to 3.
From the Laboratory of the

WM. S. MERRELL CHEMICAL CO.
Manufacturing Chemists, Cincinnati, Ohio

I should like your opinion as to the sale of drugs by a large drug firm like that of William S. Merrell, which is supported by the physicians of this country.

R. D. STOUT, M.D., Berryburg, W. Va.

ANSWER.—Claiming that physicians demand that they be supplied with "a pill for every ill," most pharmaceutical houses supply not only Pills Gonorrhea, but also Pills Spermatorrhea, Pills Leukorrhea, Pills Dysmenorrhea, etc. On examining the price-lists of the larger pharmaceutical houses we find that Pills (or Tablets) Gonorrhea having essentially the composition given by our correspondent appear in the catalogues of Eli Lilly & Co., Frederick Stearns & Co., Parke, Davis & Co., and Sharp and Dohme, while Tablets Gonorrhea having a different composition are listed in the price-list of the H. K. Mulford Company.

The objection to therapeutically suggestive names for medicinal preparations has often been discussed in THE JOURNAL. The practice is an invitation to the thoughtless physician to prescribe without due consideration of the patient's needs and suggests counter-prescribing to the pharmacist. That the naming of remedies after the diseases in which they are to be used is not an economic necessity is best illustrated by the fact that E. R. Squibb and Sons are eliminating such therapeutically suggestive titles from their price-lists.

THE RECTOVESICAL POUCH

To the Editor:—Referring to Abstract 126 in THE JOURNAL, Sept. 27, 1913, p. 1082, I should like to ask if the term "pouch of Douglas" can be applied to the male? Embryologically speaking, there may be a pouch of Douglas in a man, but is this the case from a clinical-anatomic point of view—that is, has a man a pouch of Douglas? I understand that this pouch is formed by the recto-uterine folds of the peritoneum. I have recently had it demonstrated to me that a man could have "hysteria."

FRANK A. WOODWARD, M.D., Los Angeles.

ANSWER.—We know of no authority in English for giving Douglas any claim to the reflection of the peritoneum in front of the rectum in males, but the Germans are more generous and connect his name with that region in both sexes. Of the two patients referred to in the abstract, one was a *Wirthschaftsbesitzer*, the other a *Bauer, and the sentences in question* in the original German are: Zunächst rechter Pararektalschnitt zur Entleerung und Drainage des Douglasraumes and reichliche Spülung aller Teile der Bauchhöhle wobei fäkulente Massen, namentlich aus dem Douglas, ausgeschwemmt werden.

CATHETERIZING THE NEW-BORN—PROPER TIME OF CIRCUMCISION

To the Editor:—1. How long should we wait before catheterizing a new-born baby when it does not micturate from birth, and how many hours can we wait before repeating?

2. If the foreskin of a new-born baby is such that a circumcision is required, at what age is it advisable, in cases in which it does not obstruct micturition?

L. T. A. HOTTENDORF, M.D., Bloomington, Idaho.

ANSWER.—1. The first question calls attention to a bad practice which seems to be somewhat wide-spread, namely, catheterizing a new-born baby. It is unjustifiable, harmful and not sanctioned by the best authorities. Absence of micturition in the new-born is due to lack of urine in the bladder. The renal secretion is usually scanty for the first two days and often less than one ounce. The kidneys frequently contain infarcts of urates and uric acid. The proper management is to give water by the mouth or by enemas to supply a solvent and help to "wash out" the kidney. Warm baths may also be of advantage.

2. A large healthy child that is gaining in weight may be circumcised in the second week after the navel has healed. A puny baby should not be circumcised until it has begun to gain. It is generally possible to release the foreskin by the dilating and breaking of the adhesions to the glans. This operation may require more care for three or four days than a circumcision, but it has its advantages.

"THE WONDERS OF RECENT PATHOLOGIC RESEARCH"

To the Editor:—I have been asked to furnish material for a paper entitled "The Wonders of Recent Pathologic Research," to be read before the local branch of the Woman's Federation, and I herewith pass the request on to you.

FRED LEE MORSE, M.D., Lake Odessa, Mich.

ANSWER.—The following popular articles may be of service:

Big Battles Against Disease (The Conquest of Germs), *Outlook*, Dec. 24, 1910.

Fletcher, W.: The Need of Physical Exercise in the Treatment of Tuberculosis, *Wisconsin Med. Jour.*, June, 1910.

The Snare of the Loaded Rectum.—A loaded rectum is another source of difficulty. Some swelling may be felt behind the uterus and vagina, and we must beware of believing and especially of saying—that there is a tumor there until a finger has been introduced into the rectum. A patient's confidence in her medical attendant is shaken by the extrusion of her tumor into the bedpan.—Arthur E. Giles, in (London) *Clinical Journal*.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POST-GRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

HOSPITAL REFORM IN GREAT BRITAIN

Great Britain is at present years ahead of this country in some lines of constructive activity which can be regarded as socialistic or not, depending on the point of view. The national insurance act, providing state medical attendance for about fourteen million persons, has been commented on frequently in previous issues. This is regarded by some as plain socialism, by others rather as state activity for self-protection. That it has prepared the way for the consideration of other forms of state benefit is beyond question. In a recent issue of the *British Medical Journal* appears an article by the chairman of one of the principal divisions of the British Medical Association, advocating a voluntary medical service, which would be supported by the state and which would furnish professional services at a fixed price per week, as well as paying disability and old-age pensions. As a corollary of this proposition, the hospital situation in rural districts is also discussed. Starting out with the proverbs that "health is wealth" and that "prevention is better than cure," the writer concludes that it is to the public interest to secure the highest possible skill among the largest possible percentage of doctors, and that, as this is true, physicians should not only be assured the means and the possibilities of acquiring knowledge and skill through proper training and medical schools, but, after graduation, they should be in a position steadily to increase their knowledge and skill by access to hospitals in which proper facilities for treatment are available. Criticisms of the present situation are that the existing hospitals are becoming more and more centralized, that they are limited principally to the larger cities and that the number of physicians who can secure the necessary training and experience as members of the staff is limited. The result is that the practitioner who locates at a distance from a properly equipped hospital not only does not increase his knowledge and skill by experience, but does not even retain what he has, on account of lack of opportunity to use it. The result is that, with the exception of those men whose location or ability secures them appointments on the staff of some hospital, physicians soon become rusty in their knowledge and limited in their usefulness. The remedy for this situation would be the multiplication of small hospitals, in proportion to the density of population, erecting them in the densely populated outlying districts of cities, as well as in country communities, placing them in open, healthy places convenient to main lines of travel, allowing every physician to send patients to any available hospitals and to continue treating them while in the hospital, requiring every patient to pay for his care, and compensating every physician in proportion to his hospital attendance. The results which the writer anticipates from such a plan are less damage to patients on account of removal to distant hospitals, increasing ability and efficiency of physicians and increased benefit to the patients. The system, according to the writer in the *British Medical Journal*, would be self-supporting and possibly profit-producing, after deducting the initial expense of building and equipment, which could be obtained by government loans. The capital invested would be soon saved to the community by the improved healthfulness and the shortened periods of recovery in cases of sickness. A state-aided, voluntary medical service working through a system of centralized hospitals would, in the writer's opinion, "prove an incentive to the knowledge and practice of the rules of health which would be a benefit to the community. Hospital treatment would be extended to the middle classes, while hospitals could be used as centers for public lectures on hygiene, rearing of infants, use and abuse of alcohol, etc. Last but not least, the anomaly of the most skilled of the greatest profession being expected to give of their best gratuitously, while every other trade and profession are paid "according to their skill," would cease. Whether the results indicated would be as sweeping as this is open to argument. Whatever may be the social conditions in Great Britain, the public in the United States is probably not ready for a state-aided medical service now and will not be for many years, if ever. But the hospital situation is practically the same in both countries. In this country, as in England, there are too few hospitals. The hospitals in many cases are too highly centralized, they are too largely restricted to large cities, the distance which patients must be carried is, in many cases, too great and the number of physicians having access to these hospitals for the treatment of patients and for the acquirement of professional skill is too small. The development of small hospitals in the small towns and in the rural communities, and the substitution of a number of hospital units in various parts of the larger cities, in place of a single institution of enormous size and cost, are some of the most important and necessary of reforms.

CHECKING UP ON THE HEALTH DEPARTMENT

The disastrous flood in the early part of 1913 not only caused destruction of property in Dayton, Ohio, but also left the city in a bad sanitary condition. By prompt and energetic action, however, epidemics were prevented and the general health of the citizens was not seriously affected. In the course of the rehabilitation of the city, many reforms, governmental and otherwise, were instituted, one of them being the adoption of a modified commission form of government, the principle of which is that the direction of a city's affairs is a business proposition which demands the application of business principles by a business manager. A bureau of municipal research[1] was also established, and among its first problems was the promotion of the health of the city. In order to have a correct basis on which to work an expert from the School of Public Service of the New York Bureau of Municipal Research was employed to make a survey of public health with regard to the efficiency of the health service of the city. One of the most important conclusions of the report is—and well it applies to almost every city in the land—that the want of a better regulation of health and sanitation was not owing either to ignorance of conditions or to lack of efficiency on the part of the local board of health, but "largely and chiefly to the mistaken policy which leads to an insufficient appropriation for the needs of the department; to lack of cooperation by some departments of the city government, and largely to the apathy of the people in matters pertaining to public health." Beginning with headquarters, the report shows that the "health office is badly lighted, poorly arranged and inadequately equipped," and that, as a result, the efficiency of the department is diminished fully 25 per cent. Lack of full-time officers is also given as a cause of decreased effectiveness. Referring to the question of appropriations, it is said that during 1912 a sum a little in excess of twenty-one thousand dollars, or about thirteen cents per capita, was expended for health conservation, while the appropriation for such purposes in a city the size of Dayton should be at least eighty or eighty-five cents per capita. As a consequence of, or at least under this inadequate expenditure, three epidemics of contagious and preventable disease occurred in 1912 which, on account of closure of schools, financial loss on account of sickness and death, etc., cost the city, as estimated, approximately two hundred thousand dollars, or practically ten times the amount of the health appropriation. When a proposition such as this comes up to the new business manager of Dayton, if he applies even ordinary business principles, it should not be difficult to predict his recommendation. The report of the expert takes up all phases of the health service of Dayton and makes constructive suggestions in regard to its betterment. Conditions in Dayton are cited, not to show the deficiencies of its health department, which was no doubt better than those of many other cities, but to emphasize once more the apathy of the people and their representatives in local government in regard to health matters, and the ridiculously inadequate appropriations for the work of sanitation and disease prevention. No expenditure or investment could possibly bring larger or more satisfactory returns.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Regular, State Capitol Bldg., Little Rock, November 11-12. Sec., Dr. W. S. Stewart, Suite 404 Citizens Bank Bldg., Pine Bluff; Homeopathic, Little Rock, November 11. Sec., Dr. Ida J. Brooks, E. 10th St.; Eclectic, Little Rock, November 11. Sec., Dr. C. E. Laws, 712 Garrison Ave., Ft. Smith.

CONNECTICUT: Regular, City Hall, New Haven, November 11. Sec., Dr. Charles A. Tuttle; *Homeopathic*, New Haven, November 11. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.; Eclectic, New Haven, November 11. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

FLORIDA: Jacksonville, November 12-13. Sec., Dr. J. D. Fernandez.

MAINE: City Hall, Portland, November 11-12. Sec., Dr. Frank W. Searle, 776 Congress St.

NEBRASKA: Lincoln, November 12-13. Sec., Dr. H. B. Cummins, Seward.

NEVADA: Carson City, November 3. Sec., Dr. S. L. Lee, Carson City.

SOUTH CAROLINA: Columbia, November 11. Sec., Dr. A. Earle Boozer, 1806 Hampton St.

TEXAS: Bender Hotel, Houston, November 11-13. Sec., Dr. W. L. *Crosthwait, Suite 1003, Amicable Bldg., Waco.*

WEST VIRGINIA: Hotel Chancellor, Parkersburg, November 10. Sec., Dr. S. L. Jepson, Wheeling.

New Mexico July Report

Dr. W. E. Kaser, secretary of the New Mexico State Board of Health and Medical Examiners, reports the written examination, held at Santa Fe, July 14-15, 1913. The number of subjects examined in was 13; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 2, both of whom passed. Four candidates were licensed on presentation of satisfactory credentials and one through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery	(1913)	93.7
Barnes Medical College, St. Louis	(1909)	82.5

LICENSED ON PRESENTATION OF SATISFACTORY CREDENTIALS

College	*Year of Graduation*
University of Louisville	(1912)
Tulane University	(1897)
Baltimore Medical College	(1891)
Vanderbilt University	(1894)

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
College of Physicians and Surgeons, St. Louis	(1909)	Oklahoma

South Dakota July Report

Dr. P. B. Jenkins, secretary of the South Dakota State Board of Health and Medical Examiners, reports the oral and written examination held at Pierre, July 8-9, 1913. The number of subjects examined in was 13; total number of *questions asked. 100; percentage required to pass, 75.* The total number of candidates examined was 16, of whom 15 passed and 1 failed. *Three candidates* were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Colorado	(1913)	88, 91
College of Physicians and Surgeons, Chicago (1911) 84; (1912) 79, 89; (1913) 90, 90.

* No grade given.

The following questions were asked:

ANATOMY

1. Describe upper extremity of humerus, including attachments of muscles. 2. Name cavities of the heart and describe the valves. 3. Name salivary glands and locate orifice of their ducts. 4. Give foramen of exit from cranium, distribution and function of the pneumogastric nerve. 5. Name muscles of the eyeball and eyelids, and give their nerve-supply. 6. Through what vessels does blood pass in going from the external saphenous vein to right index-finger? 7. Name muscles on back of leg. 8. Describe the pharynx. 9. Describe gross anatomy of the liver. 10. Describe the thyroid body.

CHEMISTRY

1. Distinguish between "chemical" and "physical" changes in matter and give an example of each. 2. (*a*) Define an acid. (*b*) Give formula of one inorganic acid and show how this formula fulfils the conditions stated in your definition. (*c*) Give the name and formula of one organic acid. 3. (*a*) Should a physician *order* iodid of potash and corrosive sublimate in the same solution, what chemical and physical changes would take place in the mixture? (*b*) Would the resulting products be harmful to the patient *and*, if so, which? 4. Complete the following equations: $MnO_2+H_2SO_4 =$; $2KI+FO_2=$; $3H_2O+P_2O_5=$; $C_2H_5OH+H_2SO_4=$. 5. Write the graphic formula of marsh gas *and* (*b*) illustrate by graphic formulae its relation to wood alcohol. 6. (*a*) What are carbohydrates? (*b*) Name three substances belonging to *this group*. 7. (*a*) Iodin—Give its (1) valence, (2) method of preparation, (3) *test for iodin.* (*b*) Give name and formula of one of its organic and one of its inorganic compounds. 8. How would *you know that* a given white powder was calomel and not ordinary bismuth? 9. On what chemical *fact* does Fehling's test for sugar depend? 10. (*a*) *Give the*

most important constituents of normal gastric juice. (b) What is the action of normal gastric juice on: (1) proteids, (2) fats, (3) carbohydrates in the ordinary course of digestion?

PHYSIOLOGY

1. Give reaction of the following and state cause of reaction: Gastric juice, blood, urine, and pancreatic juice. 2. Describe briefly the physical and morphologic changes of the leukocytes. 3. What are carbohydrates and what part do they play in the general metabolism? 4. Describe briefly the physiology of the clotting of blood. 5. Define anabolism, osmosis, dialysis and rigor mortis. 6. State some of the conditions which produce variations from the normal temperature of the body. 7. State briefly what is meant by the vasomotor nervous system. 8. Describe the fetal circulation. What changes in the circulation take place at birth? What is the physical condition of the child if such changes do not take place properly? 9. Describe the physiology of menstruation. 10. What is meant by secretions? What is the difference between external and internal secretions? Give examples of each.

PATHOLOGY

1. Describe *Trichina spiralis*, giving life cycle, and morbid anatomy of trichiniasis. 2. Mention two or more conditions that prevent the passage of urine from the male bladder, and describe the process which causes one of these conditions? 3. Mention six varieties of calculi and describe the formation and composition of one variety. 4. What are the signs of death? Sketch the method of doing a complete necropsy. 5. Give the pathologic changes occurring in acute bronchitis? 6. Mention the lesions of typhoid fever. What is a typhoid carrier and how recognized? How is antityphoid vaccine prepared 7. Describe the healing of an uninfected wound. 8. Give the characteristics of a malignant growth. Mention at least four varieties which affect the breast and describe one. 9. Discuss anaphylaxis. 10. Describe the morbid process occurring in a tuberculous hip which is untreated, resulting from bony ankylosis.

PRACTICE

1. Define: (a) Ulcerative stomatitis. What remedy is specific for this dis[illegible] pupil. In what disease does it occur? [illegible] d) Anuria. Hematuria. Polyuria. (c) [illegible] in which it occurs as a late complication. 2. Define: (a) Nephrolithiasis and cholelithiasis. (b) Landry's paralysis. (c) Name the various valvular diseases of the heart. (d) Enteroptosis. (e) Dysphagia. Name some diseases in which it occurs. 3. Diagnosis—Define: (a) Tonic and clonic spasms. (b) Hemoptysis and hematemesis. (c) Sibilant and sonorous râles. (d) What is tic douloureux and how would you treat it? 4. What are the physical signs of pulmonary solidification and pleuritic effusion 5. Differentiate: Follicular tonsillitis and diphtheria. 6. Name the day of eruption in small-pox, chicken-pox, measles and scarlet fever. 7. Give diagnosis of intestinal obstruction and name three types. 8. Treatment. Give treatment of nephritis and name both types. 9. Being called to a case of pulmonary tuberculosis in its early stages what symptoms would you find, and what measures would you employ? 10. Pellagra. What are its symptoms and how would you treat them?

THERAPEUTICS

1. Explain the action of diphtheria and tetanus antitoxin as prophylactic and curative agents. 2. Write a *prescription* in Latin, without abbreviation, containing three ingredients which you would use in the treatment of acute *pharyngitis*. *3. Write a prescription* in Latin, without abbreviation, containing four liquid ingredients; state conditions for which it is intended and give directions for its use. 4. Name three *official preparations* of ammonium and give their therapy. 5. Hyoscyamus: Its *active* principle, physiologic action and therapy. 6. Belladonna: Its active principle, physiologic action and therapy. 7. *Digitalis: Its* active principle, physiologic action and therapy. 8. Give an example of a prescription showing a chemical incompatibility and describe the incompatibility. 9. Give the *physiologic action* of nitroglycerin and indications for its use. 10. Name the chlorids of hydrargyrum, therapy, symptoms and treatment of poisons.

OBSTETRICS

1. Describe the changes that take place in the organs of the mother during *normal pregnancy.* 2. *Give the classification* of contracted pelvis. 3. Describe the sutures, fontanels and protuberances of the presenting fetal head. 4. What is kyphosis and its influence *on* labor? 5. Give the diagnosis of tubal pregnancy before rupture. 6. Mention the different *methods* of *dilatation* of the cervical canal for delivery of the fetus. 7. Give the indications for version. 8. What are the dangers in *forceps* delivery? 9. Describe the physiologic lochia. 10. Describe briefly the operation trachelorrhaphy.

SURGERY

1. Give symptoms and treatment of chronic purulent otitis media. 2. Name conditions which may cause inability to pass urine, with *symptoms of each. 3. Give symptoms,* [illegible] ent of Pott's disease in the dorsal region. 4. [illegible] treatment of acute glaucoma. 5. Give sym[illegible] of a fracture of a rib. What complications [illegible] symptoms, diagnosis and treatment of cholelithiasis. 7. Give symptoms and signs of thoracic *aneurysm.* 8. *Define* surgical shock; give symptoms, signs and treatment. 9. A *patient having received* a severe *blow* over left temporal region, is unconscious for a time, paralysis *coming* on late. Discuss the possibilities. 10. Give symptoms, diagnosis and treatment of carcinoma of the *rectum.*

MATERIA MEDICA

1. Bismuth, betanaphthol, camphor and aspirin. The official preparations and dose of each. 2. Give source of sugar of milk, hexamethylenamin, phenol, pepsin and glycerin. 3. Name the alkaloids of nux vomica. 4. *Belladonna.* The official preparations and doses. 5. Cocain, codein, colchicum, colocynth. *The official* preparations and doses. 6. Define extracts. Give five official extracts with average dose of each. 7. Name three *drugs* which may produce a rash and describe such rash. 8. Write a prescription for thirty-six pills, *for an adult,* containing iron, quinin, strychnin and arsenic. 9. Name three external and three internal antiseptics and give strength in which they are generally used. 10. What are *antitoxins?* Name three. Give average dose and how administered.

Book Notices

MARRIAGE AND GENETICS. Laws of Human Breeding and Applied Eugenics. By Charles A. L. Reed, M.D., F.C.S., Professor in the University of Cincinnati. Cloth. Price, $1. Pp. 183. Cincinnati: The Galton Press, 1913.

In spite of the enormous amount of material recently published on marriage, sex hygiene and kindred topics, this book has a definite place and mission, and is certain to attract the attention and careful study of all those sincerely interested in social betterment. Not only on account of the high professional standing and personal prominence of the writer, but also on account of the manner in which the subject is presented, Dr. Reed's book will be accepted by the medical profession as one of the best discussions of marriage and eugenics which the physician can place in the hands of his patients. Its objects, as set forth in the introduction, are to "overcome the ignorance which in too many instances keeps innocent victims from protecting themselves and their offspring from disease and degeneracy," "to avert many of those conditions that destroy the possible happiness of the marriage state, and convert the bridal chamber into the anteroom of the divorce court." The carrying out of this purpose has made it necessary for the author to consider the laws of human breeding and to explain them in terms comprehensible to the lay reader. This has been accomplished by the formulation of ten fundamental laws of race perpetuation, which the author designates as "the decalogue of human breeding." The discussion of these subjects comprises the first half of the book, which consists of an introduction, stating the problems involved in general terms, and a discussion of the general laws of genetics, in chapters on life, continuity of human life, sexual efficiency, character units, inheritance, heredity, the human norm, growth and reproduction, food and fecundity, and natural selection. The second division is given to a consideration of social diseases under the heading of "Race Poisons," while the third and last part of the book, designated as "Applied Eugenics," discusses the details of such physical examinations and conditions as are necessary to detect unfitness for marriage, also a summary of the various characteristics transmissible from parents to offspring, and the conditions under which such transmission occurs. In spite of the enormous amount of ground covered, the book is concise and compact. It is, therefore, well adapted for the general public, as it omits all discussion over controversial points. Specially praiseworthy is the entire absence of the sermonizing and moralizing that characterizes many popular books on similar subjects. The facts regarding heredity, eugenics and degeneracy are given in plain, simple language, perfectly comprehensible to any one of average intelligence. The book is a valuable contribution to the popular literature on the subject and cannot fail to be of enormous social service.

DISEASE OF THE EAR. By Philip D. Kerrison, M.D., Professor of Otology, New York Polyclinic Medical School and Hospital. Cloth. Price, $5. Pp. 588, with 333 illustrations. Philadelphia: J. B. Lippincott Company, 1913.

This book is an index of the manner in which the subject of otology has developed in recent years. It is filled with information presented in concise and direct form with no unnecessary padding. Each subject seems to be given adequate treatment. The anatomic and physiologic aspects of the aural and surrounding structures are clearly and beautifully described and illustrated by numerous splendid drawings which cleverly illustrate the points aimed at. Surgical procedures are equally well described, and in matters of diagnosis and treatment the author displays the ripe judgment of large experience. It is equally satisfactory in the manner in which the more common and more simple affections of the aural apparatus are described, and in the more technical matters pertaining to the detection of impairment of the sense of hearing and the function of equilibrium and the intricate operations on the mastoid and the middle and internal ear. Chapters are included on tuberculosis of the ear, auditory nerve lesions of syphilis, and those following the use of salvarsan, a number of which have been reported. Serum and vaccine therapy in the treatment of aural diseases are also covered briefly, as are aural disturbances due to dental lesions, deaf-mutism and the question of adenoids. In an appendix, aural disease in relation to life insurance, artificial aids to hearing, the manner of recording histories, and various formulas for sprays and other applications are found. Unnecessary mention is made of a number of proprietary preparations, some of which are decidedly out of place in a book that makes a pretence of being scientific.

Modern Progress and History. Addresses on Various Academic Occasions. By James J. Walsh, K.C.St.G., M.D., Ph.D., Dean and Professor of the History of Medicine at Fordham University School of Medicine. Cloth. Price, $2 net. Pp. 450. New York: Fordham University Press, 1912.

Physicians pay far too little attention to the history of their profession. The average physician knows little regarding medical knowledge, theories, or conditions of previous generations. Much of the inability of physicians to explain and counteract the fads and cults which are constantly springing up is due to their lack of knowledge of the rise and fall of many similar movements. A comprehensive review of the history of medicine with sketches of some of the great leaders and pioneers in scientific work should be one of the first things presented to the medical student.

Physicians of all ages and classes who are really interested in their profession will find many things to hold their attention in Dr. Walsh's book. It contains eleven addresses delivered on various occasions and all bearing on educational or scientific questions. The first chapter, "Prescriptions, Old and New," contains many interesting examples of old and curious prescriptions. The second chapter, on dentistry, shows the development of this art in early times and its progress to the present day. The chapter on "Professional Life and Community Interests" can be read with profit by every medical student. While every reader may not agree with Dr. Walsh in his general proposition that modern progress does not represent as great an advance over the accomplishments of previous generations as is generally supposed, no thoughtful reader can fail to find these essays both interesting and stimulating.

Therapeutics of the Gastro-Intestinal Tract. By Dr. Carle Wegele. Adapted and Edited with Additions on the Diagnosis of the Diseases of the Esophagus. By Maurice H. Gross, M.D., Attending Gastro-Enterologist to the Har Moriah Hospital, and I. W. Held, M.D., Attending Physician to the Har Moriah Hospital. Price, $3 net. Pp. 329, with 54 illustrations. New York: Rebman Company, 1913.

The editors have undertaken the task of producing an American edition of Wegele's book, because in their opinion it is an especially conscientious and thorough treatise on the subject. In addition to translating and arranging the original material, they have added points of diagnostic interest in connection with the various diseases discussed, chapters on the esophagus, Roentgen-ray diagnosis of the stomach and intestinal diseases, and on the basis of their own researches, a chapter on the comparatively new subject of the duodenal tube. In this complete form the book should be of great use to those engaged in general practice, in that it gives concisely the therapy of many conditions whose care is extremely difficult. The literature includes all material published up to the time of going to press.

Diet in Health and Disease. By Julius Friedenwald, M.D., Professor of Gastro-Enterology in College of Physicians and Surgeons, Baltimore, and John Ruhräh, M.D., Professor of Diseases of Children in College of Physicians and Surgeons, Baltimore. Fourth Edition. Cloth. Price, $4 net. Pp. 857. Philadelphia: W. B. Saunders Company, 1913.

Since the last revision in 1909 so many changes in opinions on diet and so many new facts have been added to the subject that a revision of this volume has been thought necessary. New tables are added and many of the chapters are entirely rewritten. A section on "Mechanism of Digestion" is also included. The chapter dealing with infant feeding contains practically all that is new and accepted on this subject. The value of the book as a handbook for the practitioner on a difficult subject needs no comment.

Nierenphysiologie und funktionelle Nierendiagnostik im Dienste der Nierenchirurgie und der internen Klinik. Von Dr. Victor Blum, Privatdozenten für Urologie an der K. K. Universität Wien. Paper. Price, 4 marks. Pp. 121, with illustrations. Leipsic: Franz Deuticke, 1913.

The author has gathered the material on this subject up to the latter part of 1911. From a consideration of the various functional tests of the kidney, he concludes that modern scientific study of kidney lesions demands that functional tests be made constantly throughout the course of various kidney diseases. Apparently much material has been brought forth on this topic since the treatise was written. In view of this fact, it can form nothing more than a reference book for those interested in the subject.

Practical Bacteriology, Blood Work and Animal Parasitology. Including Bacteriologic Keys. By E. R. Stitt, A.B., Ph.G., M.D., Medical Inspector, U. S. Navy. Third Edition. Cloth. Price, $1.50 net. Pp. 408, with 110 illustrations. Philadelphia: P. Blakiston's Son & Co., 1913.

This manual continues to improve with each edition. Much has been added to the chapters on bacteriology and the work on protozoa has been completely revised. The chapter on immunity contains good discussions concerning the preparation of vaccines, agglutination tests, Wassermann reactions and anaphylaxis. A new chapter has been added on disinfectants and insecticides which gives particular application to methods of carrying out these important health procedures.

A Reference Handbook of Gynecology for Nurses. By Catherine MacFarlane, M.D., Gynecologist to the Woman's Hospital of Philadelphia. Second Edition. Leather. Price, $1.25 net. Pp. 156, with illustrations. Philadelphia: W. B. Saunders Company, 1913.

A large amount of information is contained in this little book. Especial attention is given to the preparation for operations and the assistance which a nurse should give. As its name denotes it is a convenient handbook for ready reference.

Medicolegal

Liability of Parents for Medical Services Rendered to Adult Children

(Crowell vs. Donoho (Mo.), 153 S. W. R. 1082)

The Kansas City Court of Appeals affirms a judgment for the defendant in this suit on an alleged contract of employment to recover the reasonable value of services rendered by the plaintiff, as a physician and surgeon, to an adult daughter of the defendant. The court says that at the time the services were performed the defendant was a widow, one member of whose family was an unmarried daughter over 18 years of age, who fell ill. The plaintiff was called into the case in consultation, and recalled to perform an operation for appendicitis. Afterward a second operation was performed, and still later a third. The defendant paid the plaintiff's bills for the consultation and first operation, but he was not paid for the last two operations, and this suit was brought for the recovery of the reasonable value of his services in performing them. The defendant testified, and the court found, that the payments made by the defendant for the first two visits, though paid out of the defendant's funds, were made for the patient at her request, and were charged against her inheritance, the defendant being administratrix of her husband's (the patient's father's) estate. The plaintiff's theory of an implied contract of the defendant to become liable for his services must rest on the facts that the patient was a member of the defendant's family and that the plaintiff's compensation for a part of the services rendered was paid by the defendant apparently out of her own funds, though, in reality, out of funds belonging to the patient.

The defendant was under no legal obligation to provide her adult daughter with the services of physicians, and had she called the plaintiff into the case that fact, of itself, would not have raised an implied promise on her part to become responsible for the plaintiff's employment. The rule is well settled that a mere request from a father to a physician to attend a child of full age, and for whom he is not bound to provide, and though sick at the father's house, raises no implied promise on his part to pay for such medical services. Still less, says the court in *Crane vs. Baudouine*, 55 N. Y. 256, may a promise be implied when there has been no special request by the parent to the physician, and no more than an acquiescence in his calls.

It was the duty of the plaintiff to know or to learn the true legal status of the patient, and what were her true legal relations to the defendant. If the court should hold that a parent could not be present in the sick-room of his adult child and exhibit usual parental interest and anxiety, without becoming liable to an attending physician called in by another at the patient's request, it would do violence to a wise and humane rule of universal recognition that has for its object the proper care of the sick and helpless.

The only fact remaining on which an implied promise of the defendant might be founded with any show of reason was that of the payment on behalf of the patient of the plaintiff's first two bills. It is said in *Morrell vs. Lawrence*, 203 Mo. 373, that a contract should be implied when the circumstances or conditions may be such as to lead the physician to believe, and to charge the father with knowledge that the physician does believe, that the father is undertaking to pay for the services to be rendered. In that case the father called the physician under circumstances, as pointed out in the opinion, clearly indicative of a purpose and assurance on his part that he would pay for the services; but here the plaintiff was called under circumstances that pointed to the patient as his only employer. The patient was too ill to attend to business affairs, and naturally would be expected to select her mother as her agent. Had the defendant paid the plaintiff in money, he would not have been justified in believing that she was using her own money and intended to be regarded as his employer, or as acting in any other capacity than her daughter's agent. Certainly the mere fact that for convenience she gave him her own bank checks was no indication of a purpose to vary the ordinary legal relationships obtaining in such instances. It is a very common thing for an agent to make disbursements for his principal's account in such manner, and the plaintiff was not entitled to draw any special conclusions from the method of payment employed.

The plaintiff appeared to have taken too much for granted. His cause was predicated on presumptions he had no legal right to indulge. The court does not say that the parent of an adult child may not become bound to pay for medical services rendered the child on an implied promise, but it does hold that such promise must rest on facts and circumstances that would be incompatible with any other inference than that the parent intended to be regarded by the physician as his employer. There were no circumstances in this case indicative of such intention, and the court concludes that the trial judge committed no error in rendering judgment for the defendant.

Evidence of Fall Being Primary Cause of Operation—Information Obtained by Subsequent Examination of Removed Parts Privileged

(*Jones vs. City of Caldwell (Idaho), 130 Pac. R. 995*)

The Supreme Court of Idaho holds that when a woman walking on the sidewalk of a city fell through a hole in the walk, and it was thereafter found necessary for her to undergo a surgical operation, and there was doubt and conflict in the evidence as to whether the operation was caused primarily by the fall or by a previously existing diseased and affected condition of the parts operated on, and expert testimony introduced was indefinite and uncertain as to the primary cause which rendered the operation necessary, the fact that the operation was considered necessary by the attending physicians soon after the accident occurred, and that the operation was actually performed, were circumstances which the jury had a right to consider in concluding that the fall was the primary cause of the operation and of the consequent damages sustained.

When the attending physician deems a surgical operation necessary on his patient, and another physician or surgeon is called to assist in the performance of the operation, and actually performs the operation or assists therein, and subsequently, on a trial which brings in issue the facts and circumstances which led up to and rendered necessary the operation, any information acquired by the attending physicians at the operation or subsequently acquired by examination of the parts removed by the operation is privileged information under the provisions of Section 5958 of the Revised Codes, *and cannot* be given in evidence without the consent of the patient, Subdivision 4 of Section 5958 providing that "A physician or surgeon cannot, without the consent of his patient, be examined in a civil action as to any information acquired in attending the patient, which was necessary to enable him *to prescribe or act for the patient*." The fact that certain information was gathered from examination and inspection of the injured or diseased parts removed by the operation a considerable time after the operation had been performed and the physician had acted and prescribed for the patient, does not change the privileged character of the information and permit the physician to testify concerning the same.

In this case the city contended that the operation which resulted in the removal of the fallopian tube had been performed, the tube had been removed, and that it was no longer necessary to make an examination of the removed portion, and that the information acquired from the examination was not necessary to enable the witness to prescribe or act for the patient. Literally and technically speaking, this might be true; but such a construction of the statute would rob it of its true spirit and the purpose and intent thereof. Had the physician not been called on to perform this service in his professional character, he would never have been able to acquire the information about which the city sought to have him testify. He acquired it as a physician and surgeon and in no other capacity; and he acquired it as physician and surgeon for the plaintiff, and by reason of his employment in his professional capacity to serve the plaintiff.

Liability for Negligence in the Administration of an Anesthetic—Competent Evidence and Burden of Proof

(*Spain vs. Burch (Mo.), 154 S. W. R. 172*)

The Springfield Court of Appeals reverses a judgment rendered for the plaintiff in this suit for damages for the death of his wife, caused, as was alleged, by the malpractice of the defendant, as a physician, in administering to her an anesthetic. The court does this, remanding the case for a new trial, because there was not, in the record as presented, sufficient evidence to carry the case to the jury on the ground of negligence in not making a proper examination of the physical condition of the patient to ascertain whether or not her physical condition was such as to make it safe and proper to administer the anesthetic to her; but the court is not prepared to say that there was not sufficient evidence to take the case to the jury on the ground of negligence in not using due and ordinary care in administering the anesthetic, and in watching and caring for the patient while administering it, and while she was under its influence.

The court says that it recognizes the rule that it is not sufficient that a physician possess ordinary skill, and that he use proper and approved medicines and appliances in treating the patient, but also that in treating a particular case he must in that case use such reasonable skill and diligence in applying or administering the medicine and means used. The question to be determined was whether or not the defendant did, in this particular case, use ordinary skill and diligence in administering the anesthetic to the deceased.

Nitrous oxid was the anesthetic administered, through the Teters apparatus, in an examination for hemorrhoids. The examination was made with the assistance of another physician, called in for that purpose, and a woman office assistant. It occupied no more than from three to five minutes.

The evidence of a large number of dentists and physicians, familiar with and skilled in administering this particular anesthetic, was to the effect that if a person is in apparent good health that no examination whatever is usual or necessary; that the danger from the use of this anesthetic is almost a negligible quantity, so far as the physical condition of the patient is concerned. This, however, would not prevent the case going to the jury, provided there was any substantial evidence offered by the plaintiff that ordinary skill and diligence demanded a more careful examination, or one nearer the time of the operation, than that made by the defendant the previous afternoon.

When physicians and dentists are alike used as experts on the question of the proper use of this anesthetic, and it is shown that dentists use it more often than physicians, and are often more proficient and skilled in its use than an ordinary practitioner of medicine, the usual and customary methods of using it by dentists, skilled in that respect, is a legitimate source of inquiry, and such evidence should not be excluded. The skill and proficiency by which a physician administering an anesthetic is to be judged is not to be measured by the usual and ordinary skill possessed by other physicians only, but extends to that possessed by other persons, whose occupation and study give them an equal or better knowledge of the right methods of its use than is possessed by a general practitioner of medicine.

While the fact in this case was that death occurred during the time of administering the anesthetic to this patient, yet that fact alone would not support a verdict for the plaintiff. There must be a causal connection amounting to negligence between the accident and injury. The burden was not on the defendant to show the cause of the accident. The burden was on the plaintiff to prove the negligence affirmatively.

Nor would the fact that the jury had a right to disbelieve the testimony of the defendant, as to his having made, on the previous afternoon, a careful examination of the organic functions of the deceased, help the plaintiff on this point. It is true, as the plaintiff contended, that when an issue of fact is controverted, and oral evidence must be relied on to show that fact, the jury has a right to find against the oral testimony, although it is not contradicted. But this doctrine has not been, and should not be, carried to the extent that, when the burden is on the plaintiff to show the failure to do any act, and the defendant's evidence that he did do it is uncontradicted, then the jury may not only disbelieve his evidence, but may take such disbelief as supplying the lack of affirmative evidence required of the plaintiff.

Autopsies and Public Health.—Closely connected with the problem of correct vital statistics is the question of medical competency. Many death certificates do not give the true cause of death because of the carelessness, neglect or intent of the physician; many, however, and these are numerous, are faulty because of the ignorance of the physician as to the real cause of death. Definite proof in many instances can be furnished only by autopsies. This brings us to a subject in connection with which it is entirely within the facts to say that the advancement of medical science and the promotion of public health are greatly hampered in the United States by the groundless though understandable prejudice of the general public against the extension of the privileges of hospitals in the matter of performing autopsies. This prejudice arises largely from ignorance of the importance of post-mortem examination and from popular confusion of autopsies with anatomic dissections. Unfortunately, there is a continuous effort on the part of zealous but misguided individuals and organizations to increase this prejudice by misrepresentation of the facts. The great value of autopsies, not only to the medical profession but also to the members of the general public whom that profession serves, is beyond question. If we wish to add to our store of medical knowledge, if we wish to turn out good physicians, if we are to have reliable mortality statistics there must be more post-mortem examinations in the hospitals.—Corwin and Mayo, in *The Outlook.*

STATE MEDICAL SOCIETY OF WISCONSIN

Sixty-Seventh Annual Meeting, held at Milwaukee, Oct. 1-3, 1913

The President, Dr. A. J. Patek, Milwaukee, in the Chair

Educational Reform in Medicine

Dr. A. J. Patek, Milwaukee: A wave of educational reform in medicine has swept over the country, reducing the number of medical institutions from 166 in 1907 to 110 in 1913, as the first step in that direction. I recommend the appointment of a committee to investigate the evil of fee-splitting in Wisconsin, and report at the next annual meeting; also the appointment of a committee of five for the study of the cancer problem in Wisconsin, with full scope to make the investigation as broad as it may wish, the expense to be borne by the society. The passage of the workmen's compensation act in the state will bring the physicians into closer union with industrial enterprises, and will, to a degree at least, eliminate the ambulance chaser.

Consideration of the subject of eugenics has evolved a state law compelling a medical attest of the health of one of the contracting parties, forbids consanguineous marriages, bars from marriage the epileptics, insane and those having transmissible diseases, and provides for sterilization of habitual criminals, insane, feeble-minded and epileptics in public houses and asylums, all subject to reasonable restrictions.

Intraspinous Medication in Paresis and Tabes

Dr. W. F. Lorenz, Mendota, Wis.: Intraspinous medication is a simple procedure. The Swift-Ellis method of using blood-serum has been irritating, and caused alarming symptoms. The direct injection of a dilute solution of neosalvarsan in doses of 0.0006 gm. in the male, and 0.0003 gm. in the female, caused no untoward symptoms. The direct use of neosalvarsan has apparently as much effect as the Swift-Ellis blood-serum. Intraspinous medication is a valuable adjunct in the treatment of early paresis.

DISCUSSION

Dr. L. M. Warfield, Milwaukee: In a series of experiments at the Milwaukee County Hospital we did not use the Swift-Ellis method, thinking it would be more advisable to put the salvarsan directly into the spinal canal in dilute solutions; experiments were made to find the correct dosage, in which the salvarsan proved a tremendous irritant to the spinal meninges, and we have been injecting 0.0004 mg. in 10 c.c. of fluid, and the patients have shown a marked improvement. The most valuable features of the examination of the spinal fluid are, first, the cell count; second, the globulin content.

Dr. W. F. Becker, Milwaukee: The treatment by salvarsan does not yield so good results in the parasyphilitic cases, tabes and paresis as it does in direct cerebral syphilis or postsyphilis; but the returns are coming in very fast, and everything seems favorable to the establishment of a satisfactory method of treatment.

Anesthesia

Dr. W. E. Bannon, La Crosse, Wis.: Anesthesia as generally administered has not been accorded sufficient care, and is often grossly abused by incompetent anesthetists; gas, oxygen and novocain anesthesia in the hands of experienced and competent anesthetists, and with a skilled operator, is a safe and satisfactory anesthetic for most cases of major operations; the successful use of nitrous oxid, oxygen and novocain requires, on the part of the surgeon, greater skill in operating and more careful manipulation of the tissues.

and definite knowledge of the nerve supply to regions to be blocked with the novocain, and cooperation between the anesthetist and operator. Preliminary small doses of morphin are of more benefit than harm; much lighter ether anesthesia than is usually given is sufficient for most surgical procedures.

DR. J. L. YATES, Milwaukee: I made a series of experiments on rabbits with morphin, morphin and scopolamin, nitrous oxid and oxygen, ether, chloroform and cobra venom. The observations forced the conclusion that there is no such thing as a safe anesthetic, and with it the realization that so long as poisons have to be given, the least amount of the least noxious should be administered—nitrous oxid, expertly given, often with a little ether vapor, and always mixed with sufficient oxygen to prevent cyanosis, or ether, is safest in the hands of an untrained anesthetist.

The Local Reaction Following Intradermal Injections of Tuberculin as a Guide to Tuberculin Therapy

DR. O. E. LADEMANN, Milwaukee: The administration of tuberculin consists in the application of the intracutaneous tests as defined by Mantoux as a guide to dosage. A local skin reaction consisting of redness and tenderness, measuring from 4 to 6 cm., appearing within twenty-four, forty-eight or seventy-two hours at the site of the injection, is a dose which apparently gives a pronounced local reaction in addition to stimulating the defensive powers and yet shows no evidence of a constitutional disturbance.

DISCUSSION

DR. C. H. STODDARD, Milwaukee: The cases which at the present time offer the greatest chances for control from the use of tuberculin are the surgical cases, the laryngeal cases, and those cases in which cavities are not as yet formed, and tubercle bacilli are not being thrown off. There is a growing skepticism in regard to the benefits of tuberculin treatment. I am willing to abandon it if something better is brought forward.

Osteitis Fibrosa Cystica of the Lower Jaw

DR. J. F. SMITH, Wausau, Wis.: It is difficult to differentiate these cases from sarcoma. The Roentgen ray is a valuable diagnostic agent. Amputation, resection and other operations formerly resorted to are entirely unnecessary, when we recognize the benign character of the growth. It is a mistake to inject bismuth paste or any foreign material into the cavities; a small muscle flap should be transplanted into the cavity, and the wound closed primarily.

DISCUSSION

DR. C. A. EVANS, Milwaukee: It is important to diagnose this disease, the cases being rare; a bone cyst may be looked on as a benign tumor, as far as treatment is concerned. An exploratory incision should be made in every case before a radical operation. The Roentgen ray is an invaluable help in the proper diagnosis.

The Modern Treatment of Syphilis

DR. L. SCHILLER, Milwaukee: The complement-fixation reaction is necessary in order positively to determine anything concerning the disease after the active symptoms have disappeared, and the physician is now able to determine the presence or absence of syphilis, regardless of the statements of the patient. The next advance in the treatment is the discovery of salvarsan as an efficient remedy, notwithstanding its rather stormy progress.

DR. C. F. HOOVER, Cleveland: In spite of the long clinical career that mercury has had, it is only since the Wassermann reaction, the discovery of the spirochete and the production of salvarsan that we actually know how to use mercury. The only real field for salvarsan is in those patients who cannot tolerate an adequate amount of mercury.

DR. O. FOERSTER, Milwaukee: The vital point in the present-day treatment is the possibility of sterilization of the central nervous system, and the prevention of later occurrence of tabes and paresis. One-half of the patients treated three years ago with salvarsan show absolutely normal conditions. The effect of salvarsan is more definite and more lasting than that of mercury.

DR. C. A. BAER, Milwaukee: The changes in the cerebrospinal fluid appear very early in the disease, and that is the time to institute a very strong, heavy attack.

Extrasaccular or Sliding Hernia

DR. V. F. MARSHALL, Appleton, Wis.: Extrasaccular or sliding hernia of the large intestine or bladder has a peritoneal covering which is but partial; the condition is more common than was at first believed; it owes its development to an embryologic origin; relapses are frequent and its cure may tax the ingenuity of the surgeon to his utmost. A patient with hernia of sixteen years' duration left the hospital sixteen days after the operation, having made an uneventful recovery.

DISCUSSION

DR. EDWARD QUICK, Milwaukee: In the operation we should be careful not to injure the blood-supply of the intestine which is contained in the hernia. Sometimes it is very difficult to isolate the contents of the hernia and the sac from the structures of the cord, and it has been found necessary by some operators to sacrifice the testicle in completing the operation.

The Serum Diagnosis of Pregnancy

DR. C. M. ECHOLS, Milwaukee: Fifty-seven tests were made according to Abderhalden's method. The test will probably never be simple enough for the general practitioner to carry out, but there is reason to believe that when done in properly equipped laboratories, Abderhalden's method will in the course of a year or so take its place with the Wassermann and Widal reactions in point of reliability.

DISCUSSION

DR. L. A. WARFIELD, Milwaukee: I have tried out the test in a limited number of cases at the Milwaukee County Hospital; but recently gave it up and confined myself to experiments on the detection of what are supposed to be amino-acids and products of proteolytic digestion in the urine. Can we diagnose the functional insufficiency of the kidney by means of this dialyzing test? If we can find a test which is simple, and which will enable us to prognosticate the onset of toxemia of pregnancy, we shall have advanced a tremendous step in the protection of the pregnant woman.

DR. DANIEL HOPKINSON, Milwaukee: The test requires the greatest of care, and if it were possible to substitute some form of complement fixation, it would be more reliable.

The Effect of Athletic Sports on the Heart

DR. C. R. BARDEEN, Madison, Wis.: The increasing amount of cardiovascular disease noted in this country by life insurance companies and others makes it important for the physician to make himself acquainted with the chief causes responsible for these conditions so that he can protect his patients. Overexertion in competitive sports, especially in schoolboys, is one factor. From 5 to 10 per cent. of freshmen entering the state university have cardiac hypertrophy with dilatation attributable to athletic sports. While in most cases there is good compensation, in many there are mitral murmurs and a myocardial irritability which not only keeps these students out of college sports but to some extent hampers their scholastic work in college. Practically all college students taking part in the major sports have hypertrophied hearts. While in many cases compensation is good, in a large number there is a myocardiac irritability sometimes accompanied by mitral murmurs which indicate somewhat serious lesions. In the past two years there have in addition been four cases of acute cardiac dilatation among the relatively few members of teams in the major sports to one case among the far greater number of students not members of teams. In the latter case the dilatation occurred while the student was running in the gymnasium.

Problems in Bone Surgery

DR. J. M. HITZROT, New York: In regeneration of bone my experience both clinical and experimental shows that in the healing of the bone after fracture, the periosteum and the endosteum are the chief factors in the process of repair, and that the cortical bone has a relatively slight function, if any, in the formation of the new bone tissue. The best graft is one covered by periosteum and with endosteum on its inner surface. There is a wide variation in the results obtained by the free transplantation of the periosteum, which depends on a number of factors which influence bone formation in the periosteum, such as age, the presence of blood and fibrin, which can readily be demonstrated, and certain other as yet undetermined factors which seemingly cause a failure of bone production by the periosteum under apparently identical conditions. The endosteum is as important a factor in the regeneration of the transplanted bone as it is in the healing process in fracture.

DELAWARE STATE MEDICAL SOCIETY

Annual Meeting, held October 13-14, 1913

The President, Dr. L. A. H. Bishop, Dover, in the Chair

Officers Elected

The following officers were elected for the ensuing year: president, Dr. William B. Orr, Lewes; vice-presidents, Drs. T. P. Davies, Farnhurst, and William Marshall, Milford; secretary, Dr. G. W. K. Forrest, Wilmington; treasurer, Dr. S. C. Rumford; delegate to the American Medical Association, Dr. H. W. Briggs, Wilmington.

Next meeting to be held Oct. 13-14, 1914, in Wilmington.

Disease of the Gall-Bladder and Bile-Ducts

Dr. L. A. H. Bishop, Dover: Suppurative cholangeitis is due primarily to an obstruction of the common bile duct due to a stone, with resulting dilatation of the gall-bladder and bile-ducts. The infective agent is usually the *Bacillus coli communis*.

Surgical Treatment of Tuberculous and Other Infected Joints

Dr. J. J. Jones, Wilmington: Tuberculous joints are encountered most commonly among children from 3 to 5 years of age. Forty per cent. of cases involve the hip and 10 per cent. the knee. The other joints most frequently affected are the ankle, shoulder, elbow and wrist. As a general rule the tuberculous condition is found in the short bones. It is often thought that when we find a tuberculous joint or bone we should remove the affected portion, but with a little care a great deal can be done to save these parts. My practice is to inject an iodin solution at various points around the infected joint, and, if it is necessary to cut away any tissue, to fill up the opening with powdered boric acid and tincture of iodin, about 30 minims of the tincture to the ounce of powdered boric acid. I open up every knee-joint in which fluid is found. Any general practitioner can do this. After the fluid has been removed the main thing is to prevent its return. The patient should be kept at rest and given general treatment. The joint is kept in a wet bichlorid dressing and bandaged tightly for about four days in order to prevent the return of fluid. Two hypodermic injections of morphin are usually necessary on account of pain.

DISCUSSION

Dr. George I. McKelway, Dover: I think it is bad teaching that in every such case of fluid in the knee-joint the joint should be opened. We all see cases which recover promptly with no subsequent trouble, simply by absolute rest in the plaster-of-Paris bandage for one to two weeks. I think it is a very great mistake to say that any general practitioner can safely open the knee-joint. The men who do most of this sort of surgery caution that the most absolute and scrupulous asepsis is necessary in operating on the joints or bones. Everything should be done with instruments and parts not even touched with the gloved finger because of the exceeding liability to infection.

Dr. D. W. Lewis, Middletown: I take exception to Dr. Jones' advice to open all joints in which there is fluid. I consider it bad practice always to do that and also for those to do it who are not accustomed to it.

Dr. J. W. Steele, Dover: I do not agree with Dr. Jones' practice of opening up the joint. In a recent case with effusion into the knee-joint I gave the patient half a dozen cantharides blisters about the size of a nickel and told him to place one of these blisters on the knee every third night, treating it until the entire knee was circled. By the time this was done under absolute rest the fluid had almost completely absorbed.

Dr. A. Robin, Wilmington: Three years ago I saw Dr. Jones of Liverpool operate on the knee-joint. He takes extreme precautions in preparing for the operation and never cuts without extraordinary care. In tuberculous troubles it has been found that tuberculin in larger doses than usually employed brings wonderful results. In bone diseases no diagnosis should be made unless a careful roentgenographic study has been made.

Dr. J. J. Jones, Wilmington: In answer to criticisms about opening the knee-joint, I was speaking of tuberculous and infected joints. When you have an infected joint with a large quantity of fluid in it, it should be removed, for it will destroy the synovial membrane and cartilage and eventually may destroy the bone. No one would dare open the knee-joint without having everything thoroughly sterile.

Serum Therapy

Dr. William H. Kraemer, Wilmington: In one case, in a man 46 years of age, in which cystoscopic together with microscopic examination showed tuberculous cystitis, I used tuberculin. The tuberculin injections were kept up for eight months, at the end of which time the symptom of pain in the bladder and frequency of urination had been greatly relieved.

DISCUSSION

Dr. William H. Kraemer, Wilmington: The reason I have been so determined to have the normal temperature before giving tuberculin is that, as I understand it, the idea of giving tuberculin is to establish a reaction of the body against the infection, and, if the patient is throwing out of his own accord sufficient toxic substances to produce a high temperature in the body, I feel that giving him tuberculin would only add to the reaction and that it would not bring about any favorable results.

Dr. G. I. McKelway, Dover: Tuberculin does good in tuberculous gland infections. The reason is that they are simply tuberculous infections; they are not mixed infections. Tuberculin does no good in advanced cases of tuberculosis because the infection is a mixed infection. You have not only a tuberculous condition to deal with, but what it is fair to call abscess in the lung from pyogenic organisms on which tuberculin has no effect and on which nothing will have any practical effect. The secret of using tuberculin is to use too little rather than too much. The usual mistake is that men are impatient for results and think that if a little does good a little more will do better.

The Roentgen Ray as an Aid to the General Practitioner

Dr. Henry A. Cleaver, Wilmington: The Roentgen ray is in no sense a panacea for disease either as to diagnosis or as to treatment. It is one of the most powerful aids, but requires specialized technic and training. It will never displace the clinical methods of examination. The diagnostic features are in the foreground and the element of treatment is much in the experimental stage. The future of the Roentgen ray lies largely in respect to treatment. For the patient there is always danger unless the man who is manipulating the machine knows it and knows it thoroughly. The man who has experience is the best judge when to stop. There is entirely too much promiscuous roentgenoscopy, especially with the apparatus which are designed to give impressions or results. The machines oscillate to two extremes which either will not do the work or else will burn the patient.

AMERICAN ROENTGEN RAY SOCIETY

Fourteenth annual meeting, held in Boston, Oct. 1-4, 1913

The President, Dr. Henry K. Pancoast, Philadelphia, in the Chair

Officers Elected

The following officers were elected for the ensuing year: President, Dr. Sidney Lange, Cincinnati; vice-presidents, Dr. D. D. Talley, Richmond, Va., and Albert Soiland, Los Angeles, Cal.; secretary, Dr. W. F. Manges, Philadelphia; treasurer, Dr. Leonard Reu, Buffalo; executive committee: Dr. Alfred L. Gray, Richmond, Va., chairman; Dr. George C. Johnston, Pittsburgh, and Dr. Roland Hammond, Providence, R. I.

The next annual meeting will be held in Cleveland, Ohio.

Adoption of a Standard Nomenclature for Roentgen Ray Work

On the recommendation of the Committee on Nomenclature, the society adopted the following terms for use in connection with all work in which the Roentgen ray is the agent employed:

Roentgen: To be pronounced rent-gèn.

Roentgen ray: A ray discovered and described by Wilhelm Konrad Roentgen.

Roentgenology: The study and practice of the Roentgen ray as applied to medical science.

Roentgenologist: One skilled in roentgenology.

Roentgenogram: The shadow picture produced by the Roentgen ray on a sensitized plate or film.

Roentgenograph (verb): To make a roentgenogram.

Roentgenoscope: An apparatus for examination with the fluorescent screen excited by the Roentgen ray.

Roentgenoscopy: Examination by means of the roentgenoscope.

Roentgenography: The art of making roentgenograms.

Roentgenize: To apply the Roentgen ray.

Roentgenization: Application of the Roentgen ray.

Roentgenism: Untoward effect of the Roentgen ray.

Roentgen diagnosis; Roentgen therapy; Roentgen dermatitis: These terms are self-explanatory.

The secretary was instructed to send a list of these terms and definitions to medical journals, medical publishers and lexicographers.

Journal of the Society

The Publication Committee announced that hereafter the society would publish a monthly journal, to be known as the American Journal of Roentgenology, to contain not only original articles, but abstracts of current literature in English and foreign languages dealing with roentgenologic subjects. The editor is Dr. Preston M. Hickey, 32 Adams Avenue, West, Detroit, Michigan.

The Value of Roentgenography in the Prognosis of Bone Lesions

Dr. Roland Hammond, Providence, R. I.: In bone *tuberculosis*, improvement is noted in the general condition of the patient before any change is apparent in the bone. This improvement is shown roentgenographically by the deposit of lime salts in the diseased area and in the adjacent bones. In unfavorable cases the bone undergoes a marked atrophy until its shadow is often hardly to be distinguished from the surrounding soft parts. In these two classes of cases the Roentgen examination confirms the clinical findings. There are other cases, however, in which roentgenography is an invaluable guide as to the future conduct of the case. The clinical symptoms may be unfavorable, but roentgenographic examination shows that the bone is not sufficiently healthy to permit of function in the joint. In one of the cases cited the patient's condition was excellent, and the employment of apparatus was about to be omitted. A roentgenogram was made as a precaution, and showed marked disease with no signs of healing. Soon after this the patient became worse and died in three months.

The Pituitary in Its Relation to Epilepsy

Dr. G. C. Johnston, Pittsburgh: I examined the pituitary region in every case of epilepsy obtainable, especially those in which no symptoms of pressure in the region of the pituitary (as evidenced by changes in the eye-grounds and visual fields) were present. I was very soon compelled to divide the cases into primary cerebropathies, pituitary tumors and epilepsy. In the majority of cases, little if any information was obtained by roentgenography of the first class, but there remained a second class of patients, who with an uneventful history, no injury, the ordinary children's diseases, previous good health, somewhere between the ages of 15 to 35, began to have attacks of petit mal, gradually increasing in severity and frequency.

As our investigations began to include this type of cases, we noticed decided departures from our conception of the normal in the topography of the sella turcica. These changes were but rarely found in the types of chronic epileptics, but were found with a regularity that gave rise to intense interest in the second class of cases above described, namely, those who with previous good histories, between the ages of 15 and 35, began to develop epilepsy. The changes consisted for the most part in an overgrowth of the anterior and posterior clinoidal processes, which in addition to an increase in area and length are slowly folded over and down on the pituitary gland, enclosing it within a bony basket. In addition to this process which is evidently one requiring a considerable length of time for its accomplishment, there is very often noticeable a decided difference in the size of the pituitary fossa and therefore of the gland itself. The fossa is thus largely or completely roofed over in some cases, the anterior and posterior clinoidal processes not only meet but overlap. The *frequency with* which this condition has been found in this class of cases is quite striking and suggests an etiologic relationship.

5 Urinary Lithiasis in Infancy. A. N. Collins, Duluth, Minn.
6 *Gastric Secretion of Infants at Birth. A. F. Hess, New York.

4. **Anatomy and Physiology of Infant Stomach.**—As a result of their investigations the authors conclude that there is no definite *normal* type of stomach in the infant. It is horizontal rather than vertical in position when compared with the adult type, and follows certain rather definite forms. They distinguish (1) the ovoid; (2) the tobacco pouch; (3) the pear-shaped stomach with base above and to the left. The shape of the stomach, it is said, does not even depend directly on the amount or character of the food ingested, but rather on the quantity of gas *which it* contains or acquires. Furthermore, its limits are greater than we were accustomed to believe, extending to the liver on the right and at times filling the entire *transverse* space from one abdominal wall to the other.

Of particular interest from the standpoint of diagnosis is the position of the pylorus. In the majority of cases this is found comparatively high and behind the pyloric third; at times its position cannot be determined even though we clearly see that the food and bismuth has passed out of the viscus.

This is especially true in the tobacco pouch form, in which the pylorus is forced posteriorly. The authors observed a change in form from the tobacco pouch to the bagpipe variety after the intestines have been emptied. The Rieder type was observed only once, occurring in a six-months-old infant. It appeared first as the bagpipe form, changed to a Rieder and then to a retort form.

The question of contained gas, or introduced gas, is an interesting one. In some cases the gas seems to act as a buffer, preventing the overdistention of the stomach with food. As a rule, the broader or more protuberant the abdomen of the infant, the greater the amount of gas the stomach contains. One of the most noteworthy observations made related to the rapid passage of food out of the pylorus; in a number of cases bismuth was seen in the duodenum one minute after the food had been introduced into the stomach by gavage, the average time being five minutes; in one case of the tobacco pouch, or retort form, the action was not unlike that of a siphon; after the greater part had passed through the pylorus the emptying action became slower. Except in the instances in which semisolid food (farina and bismuth) or cream were fed, the viscus tended to empty itself with unsuspected remarkable rapidity.

The authors question the advice of those who recommend placing all infants on four-hour feeding intervals, since a large number of stomachs practically empty themselves within an hour. In abnormal cases, as in infants having chronic disturbances of nutrition, the stomach began to empty itself very rapidly, and the emptying time was even shorter. Pisek and LeWald also attempted to corroborate the suggestive experiments of Cowie and Lyon on the pyloric opening and closing reflex. It was impossible to record or obtain roentgenograms of the action of the pylorus itself, because the pylorus and the first part of the duodenum are rarely visible, but the retarding action, for example, of alkalies, which they record, was well shown. They were able to verify the work of Cannon, Grutzer and Sick, that foods in the stomach do not tend to intermix.

6. **Gastric Secretion of Infants at Birth.**—According to Hess, newborn infants regularly secrete a considerable amount of hydrochloric acid before they are given any food. Among fifty-two infants varying in age from ½ hour to 18 hours, only one did not have hydrochloric acid in the stomach; in all but one instance free acid was obtained. The hydrochloric acid varies greatly in amount. Exceptionally it was found almost lacking on repeated tests (congenital hypochlorhydria or hyposecretion), or very profuse (congenital hyperchlorhydria or hypersecretion). In almost all cases acid was obtained by Hess throughout prolonged tests, in spite of the fact that food was not given to stimulate secretion. In one instance 17 c.c. of highly acid juice was aspirated in one hour and fifty minutes. Rennin, pepsin and lipase were also obtained in the (unfed) new-born. Hess claims that prevailing physiologic views cannot account for the gastric secretion immediately after birth. It is not the result of mechanical stimulation by means of the catheter, as the juice was obtained immediately on the introduction of the tube, without an intervening latent period. It may be prenatal in origin. Nor is it clear what stimulates the continued secretion which was obtained for hours. Experiments showed that the saliva is not the exciting agent; the effect of sucking could not be determined. Comparative tests of the same infants at birth and later, during the first week of life, showed that the stimulus to gastric secretion may be greater in the new-born infant which has not been fed. This chlorhydria of the new-born, Hess states, is not usually associated with increased tonicity of the pyloric sphincter, as the duodenal catheter can readily be passed through the pylorus. Even when 0.4 per cent. hydrochloric acid is instilled into the gastric cavity the catheter can be readily passed into the duodenum. However, the high acidity may at times be related to the pylorospasm or to duodenal ulcer met with in infancy.

Although gastric secretion is so marked in the newborn, duodenal and pancreatic secretion is very scanty. Nor can this secretion be readily stimulated by allowing hydrochloric acid to enter the duodenum. Evidently the mechanism of pancreatic secretion is not as easily activated in the newborn as in later infancy.

14 *"Auricular Flutter," with Report of Two Cases. F. T. Fulton, Providence, R. I.

7. **Typhoid Infection.**—The following represents a summary made by Cummins and Brown of cases illustrating atypical conditions and complications. Among 149 patients treated since September, 1909, there have been 11 deaths—7.3 per cent.; with meningitis, chronic nephritis and purulent appendicitis, each 1 case; intestinal hemorrhage, 2 cases; perforation and possibly embolism, each 3 cases. There were 3 paratyphoid cases. Relapses developed in 9 cases, of which one appeared as late as four weeks after leaving the hospital. The longest febrile period of relapse was thirty days and the shortest, nine days. One patient developed a second attack of typhoid fever after a six-year interval. The earliest intestinal hemorrhage occurred on the third day. Two cases were fatal and of 11 others, 4 were severe and 7 were mild. Pleurisy with effusion (organism?), meningitis and pneumonia (*B. typhosus*), neuritis in leg, neuritis in shoulder, periostitis of tenth rib and perforating duodenal ulcer were each noted in one case. The ulcer patient was operated on on the twenty-ninth day, but the lesion was not determined as typhoidal. Two patients presented an initial appendicitis, the operation being followed by the development of typhoid fever. Another patient during the course of typhoid infection developed the symptoms of perforation; operation was performed and a ruptured appendix was disclosed. Phlebitis of the leg developed in 7 cases, and of these there were 4 in the second week, 2 in the fifth week and 1 in the third week after discharge. Thrombosis or embolism was suspected in the lungs in 4 cases and in the mesenteric veins in 3 cases. These occurred from the sixth to the thirty-fifth days, and were not severe, except in 2 cases of pulmonary embolism. One patient died promptly, and the other, occurring on the thirtieth day, resulted in gangrene from which the patient was convalescent on the one hundred and ninety-first day. Chills and fever were noted in 13 cases of which phlebitis of the leg was the etiologic factor in 3. Malaria may have been a factor in another case. Chills occurred during the first week in 4 cases, second week in 2 cases, third week in 4 cases, fourth week in 2 cases and sixth week in 1 case.

8. **Absorption of Protein Without Digestion.**—Van Alstyne's experiments demonstrate that protein may be absorbed unaltered through the intact epithelium of the gastro-intestinal tract. Conditions which interfere with normal digestive function, such as ligaturing a portion of the intestine, or the whole stomach, or the isolation of a portion of the intestine as a Thiry-Vella fistula, markedly increase the amount of protein absorbed. The amount of protein absorbed without digestion under physiological conditions is too small to be of any significance as a factor in nutrition. Edestin and egg albumin when injected intravenously into a dog do not remain in the circulation in a condition to sensitize guinea-pigs for a long period; in our experiment for three days. On the other hand, horse serum may be detected in the dog's circulation for a period of at least forty-nine days. The absorption in the duodenum differs from that in other portions of the intestine in that the ligation of the duodenum does not facilitate absorption of unaltered protein.

13. **Blood-Pressure in Tuberculosis at High Altitude.**—From a study of six hundred cases Peters and Bullock draw the following conclusions: The blood-pressure is increased at elevations of 6.000 feet. The blood-pressure of both normal individuals and consumptives is higher at 6,000 feet than at sea level. The pressure tends to increase up to certain limits with continued residence. From a prognostic standpoint the blood-pressure findings are of great value in tuberculosis. There is no relation between the degree of involvement and blood-pressure, but there is a constant relation between the degree of toxemia and blood-pressure.

14. **Auricular Flutter.**—A man of 48 suffering from progressive chronic nephritis with paroxysmal dyspnea and considerable edema, suddenly developed an irregular heart action after nearly three months in the hospital. This lasted for a month, when the rhythm suddenly became normal. There were no noticeable symptoms with the onset or end of the attack but the edema was considerably more marked while the condition persisted. Cheyne-Stokes breathing was present at the time of the return to the normal rhythm. Digitalis in moderate doses of the tincture was being administered during most of the time of the irregularity. The tracings indicate that the irregularity was due to a very rapidly beating auricle, associated with irregular ventricular responses.

A man aged 54, with gradually increasing dyspnea and edema for a year, came under observation with chronic nephritis and an enlarged heart in stage of decompensation, and a pulse of 136 to 138 uninfluenced by posture or exercise. Auricular waves were present in the venous tracing at the rate of 272 per minute, indicating a 2:1 block. With rest in bed improvement was steady but the pulse was not slowed until after eight days of digitalis, when it became irregular, the latter being due to an increased grade of heart-block. Six weeks later the auricle was found to be in fibrillation.

The two cases reported by Fulton present certain points of similarity. Both patients were near the end of the fifth decade of life. In each case there was some arterial hypertension, some chronic disease of the kidneys, some cardiac hypertrophy with cardiac insufficiency associated with dyspnea and edema. In one instance the onset of the abnormal rhythm and the reestablishment of the normal rhythm occurred while the patient was under treatment in the hospital. Tracings were not taken immediately before the rhythm returned to normal, so whether it passed through the stage of fibrillation is uncertain. The duration of the abnormal rhythm was about a month. In the other case, the auricle was in flutter when the patient came under observation. It passed into fibrillation about six weeks later and has remained in that state.

Boston Medical and Surgical Journal

October 16, CLXIX, No. 16, pp. 557-591

15 *Relationship between Gynecologic and Neurologic Diseases. W. P. Graves, Boston.
16 Pellagra in Massachusetts. J. B. MacDonald, Hathorne, Mass.
17 *Surgery of Biliary Passages from Jan. 1, 1901, to Jan. 1, 1911, at Massachusetts General Hospital. W. Whittemore, Boston.
18 Pathologic Lesion of Whooping Cough. F. B. Mallory, Brookline, Mass.

15. **Gynecologic and Neurologic Diseases.**—Graves emphasizes that there exists no mysterious or peculiar nerve connection between the female genital organs and the central nervous system, and that disturbances in the former cause manifestations in the latter by the irritation of pain and discomfort.

17. **Surgery of Biliary Passages.**—Whittemore has traced 467 patients. Two hundred and sixty-two had a cholecystostomy performed for cholelithiasis; 139 have remained perfectly well; 56 have had a recurrence of symptoms; in twenty cases the symptoms have recurred once or twice and the patient has remained well since. Forty-seven are dead. Of these cases traced, 21 per cent. had recurrences. Fifty-nine had a cholecystostomy for cholecystitis; 29 have remained perfectly well; 16 have had recurrences. One patient, who is now well, had several recurrences, and 13 are dead, showing 27 per cent. of recurrences in the fifty-nine cases traced. Eighty-nine patients had a cholecystectomy for cholelithiasis; 63 have remained well, 5 have recurred, one recurred once or twice, is now well, and 20 are now dead. In the 89 cases traced, 5.6 per cent. show a recurrence. Twenty-five patients had a cholecystectomy for cholecystitis. Nineteen have remained well, in two the symptoms recurred, and four are now dead; 8 per cent. of recurrences in the twenty-five cases traced. Of 14 patients with cholecystostomy and choledochotomy, 9 have remained well, 2 recurred and 3 are dead. Seven had a cholecystectomy and choledochotomy. Two have remained well. 5 are dead. Five cases of choledochotomy traced, 2 remained well, 1 recurred, and 2 are dead. Two patients having a cholecystostomy and duodenotomy have been traced, 1 has remained well, 1 is now dead. One case has been traced that had a cholecystectomy and duodenotomy, and this patient is dead. Two patients that had a cholecystenterostomy have been traced; 1 has remained well, 1 died. Out of a total of 467 patients traced, having had these various operations, 246 have remained well, with no recurrences; 82 have recurred and are apparently no better following the operation. This shows a percentage of 17 per cent. of recurrences. Twenty-two patients have had one or two attacks of colic and have remained well since then; 97 are now dead.

Twenty-five patients having had a cholecystostomy for cholelithiasis at the first operation have had secondary operations. Eight had a cholecystostomy for cholelithiasis done. Of these eight, 1 has had a further recurrence of symptoms, 4 have remained well, 1 died at home and 2 have not been traced. One patient had a cholecystostomy for cholelithiasis and choledochotomy at the second operation. This patient died following the operation. Seven patients have had a cholecystectomy at the second operation; 3 have remained well, 1 died following the operation, 1 died at home, 2 have not been traced. Six patients had a choledochotomy at the second operation; 4 have remained well, the other two not traced. One patient had a choledochotomy and a duodenotomy; this patient died following the operation. Two patients had adhesions broken up at the second operation. Both these cases have had recurrence of symptoms. Ten patients having a cholecystostomy for cholecystitis at the first operation have had a second operation. Two of these had a cholecystostomy for cholelithiasis at the second operation. One has remained well, 1 was not traced. One patient had a cholecystostomy for cholecystitis and a choledochotomy at the second operation; this patient not traced. Two patients had a cholecystectomy at the second operation; 1 remained well, 1 died following the operation. One patient had a choledochotomy at the second operation, and this patient has remained well. Two patients had a cholecystenterostomy at the second operation. One died following the operation; the other was not traced. Two patients had adhesions broken up at the second operation; 1 died following the operation, 1 not traced. Only one patient returned for a second operation who had a cholecystectomy for stone, and no patient returned who had a cholecystectomy done for cholecystitis. The patient that returned for a second operation had a choledochotomy done and has remained well since.

At the present time 97 patients who were operated on are dead. Thirty-three have died at home since leaving the hospital and the other 64 died following the operation. Twenty of these died from peritonitis, 10 from hemorrhage, 12 from shock, 6 from pneumonia, 6 from septicemia, 3 from kidneys ceasing to functionate, and 2 from subdiaphragmatic abscess. In five cases Whittemore was unable to determine any cause for death from reading the records. Of the 33 that died at home, 8 died with further symptoms of disease of the bile passages, 1 from abscess of the liver, which was found at autopsy, and 1 from cancer of liver and gall-bladder, also found at autopsy. Two died with recurrence of the old symptoms, 4 died following a secondary operation which was performed outside the hospital. The others died from pneumonia, tuberculosis, apoplexy, nephritis and following childbirth, and in 10 cases Whittemore was unable to find out the cause of death.

36 Pellagra. A. Davidson, Los Angeles.
37 Traumatic Hysteria. J. T. Fisher, Los Angeles.

35. Intensive Strychnin in Trifacial Neuralgia.—Orbison's paper contains the clinical records of five cases of trifacial neuralgia (one case being multiple neuritis plus trifacial neuralgia), in which the treatment consisted of strychnin exhibited in large or massive doses. All of these cases contain a record of infection. This seems to Orbison to be the important indication for the exhibition of strychnin. In contrast to these, and for the purpose of calling attention to the fact that strychnin is not held to be a specific in every painful condition of trifacial distribution, Orbison cites five cases as examples of other and separate types of trifacial nerve pain in which rational therapeutics seemed to indicate different and differing methods of treatment, and in which the results have been likewise happy. Of the latter five, one was of hyperemic headache secondary to ovarian dyscrasia and cured by appropriate surgical measures and organotherapy; the second was a typical indurative headache that was speedily cured by the application of correct massage and moist heat to the indurations, together with internal administration of salophen and the iodids; the third was a combination of migrain with psychasthenia that was cured by the "training camp" method; the fourth, an incipient arteriosclerosis and fatigue neurosis, in which rest, hydrotherapy and thyroid extract were the curative measures; the fifth is a typical migrain associated with an unsuspected syphilis in which salvarsan is being exhibited because the presence of syphilis was demonstrated by a positive Wassermann of the spinal fluid. This case is still under observation. The strychnin treatment was given by mouth or hypodermically in 1/40 to 1/30 grain doses hourly for four hours morning and evening.

40. Causes of Continued Fever in Children.—The most common causes of continued fever in childhood are classified by Phillips as follows: 1. General infectious diseases such as typhoid, malaria, tuberculosis, influenza, septicemia syphilis. 2. Infections of the nose with its accessory sinuses, the ear and tonsils. This would include nasopharyngitis, infections of the antrum of Highmore, the ethmoidal and sphenoidal and frontal sinuses, otitis media with or without mastoiditis, and chronic tonsillitis. 3. Oral infections, particularly pyorrhea alveolaris. 4. Glandular inflammations, such as cervical adenitis or inflammatory conditions of the mediastinum and retroperitoneal glands, tuberculous peritonitis. 5. Diseases of the lungs and pleura, especially empyema bronchiectasis and abscess of the lung. 6. Chronic endocarditis and pericarditis with effusion. 7. Chronic appendicitis, constipation, colitis, starvation. 8. Infections of the urinary tract and vagina, pyelitis, nephritis, cystitis, gonorrheal vaginitis. 9. Diseases of the bones and joints. 10. Anemic conditions—pernicious anemia, Hodgkins' disease, leukemia, infantile scurvy. 11. Heat congestion due to insufficient radiation as seen in premature infants. 12. Chronic diseases of the brain and meninges—brain abscess, meningitis.

51 *Antityphoid Vaccination. G. V. Rukke, St. Louis.
52 Degeneration Common to Alcoholism and Inebriety. T. D. Crothers, Hartford, Conn.

47. Artificial Pneumothorax in Lung Tuberculosis.—Gray is of the opinion that artificial pneumothorax offers much in selected cases and that no progressive case should be given up without at least considering this operation. He thinks it is better to sacrifice a partially destroyed lung than to await its almost certain destruction, because it is possible to save a fair percentage of otherwise hopeless cases.

51. Antityphoid Vaccination.—At Jefferson Barracks, a recruit depot, Rukke says they have completed 11,007 cases of prophylactic administrations of typhoid vaccine. This means 33,021 injections. Of these cases, eighty-seven were admitted to hospital as having a reaction sufficiently severe to excuse them from work. As all recruits are vaccinated for small-pox at the time of enlistment, a large number of the admissions were suffering both from vaccinia and typhoid prophylactic. Again, as prevention of epidemics is an important part of the work, infectious diseases are imported continuously. A great number of these eighty-seven admissions were admitted on account of the temperature rise on suspicion of measles and other infectious diseases. Rukke believes it to be a conservative estimate that 50 per cent. of the admissions which were diagnosed as reaction following typhoid, would not have been admitted if the patient had not had vaccinia, or had not been taken in on account of the suspicion of measles or other infectious disease.

Rukke and his colleagues have seen no serious result in any of the 33,021 doses, and so far he has heard of only one, a case of neuritis in an officer, probably due to accidentally striking a nerve with the needle. Occasionally a man the day after the prophylactic becomes weak and faint while at drill and has to fall out, but usually in a few hours is able to go on with his work, not necessitating admission to hospital or any treatment. Children bear the prophylactic well. They have administered it to children as young as 3 years. They encourage all families on the post to have their children protected, and, to a great extent, they avail themselves of the opportunity. Children do not react so severely as adults. Usually the child is cautioned not to go out in the sun, otherwise it continues its play as if nothing had happened. The dose for a child is in proportion to its weight, the basis being a man of 150 pounds. Better a little more than less the exact proportion. As the child is immunized in proportion to its weight, and its weight increases rapidly, it is advisable to repeat the immunization oftener than in adults. The immunization appears to last at least two years, probably more.

56. **Research Studies in Psoriasis.**—Nine of forty-eight cases of psoriasis. 18.7 per cent. studied by the authors, yielded positive Wassermann reactions. using an alcoholic extract of luetic liver as antigen. With antigens of cholesterinized alcoholic extracts of human and beef heart, over 28 per cent. of twenty-two cases reacted positively. From a clinical study of the patients whose serums were studied, the positive tests cannot all be attributed to syphilis. although this might be true of a few of them; on the other hand, some significance must be attached to them, which future research alone can reveal. Using for antigens aqueous and alcoholic extracts of psoriasis scales and of a large number of cultures of organisms isolated from lesions, complement fixation was not found to occur with ten serums from active cases of psoriasis. These result would indicate that either the true antigen was not present in the extracts of scales and cultures used. or that the psoriasis antibody, if it exists, was not present in the serums in sufficient amount to inactivate complement with the extracts used in this study. Sixteen different organisms were isolated from fifty-seven cultures from twenty-four cases of psoriasis. No organism was found which could be regarded as bearing an etiologic relationship to the disease.

An unidentified diplococcus "X" was found in five psoriatic lesions and in one blood-culture and is deserving of further study. The use of anaerobic methods and special culture media, composed of the scales and secretions of psoriasis, did not show the presence of any special parasite. Numerous growths of scales in moist chambers showed the presence of diplococci, but no unusual organism or fungus. Investigation with the ultramicroscope discovered the presence of a motile bacillary body in seventeen out of nineteen cases of psoriasis. In eighteen other dermatoses these were found in three instances. These bodies are being further studied. Cultures and microscopic examinations of fluid secured by blister over psoriasis lesions, yielded indifferent and inconclusive results. Inoculation experiments on monkeys, including the implantation of buttons of psoriasis skin, scales, serum and defibrinated blood, were negative in one to six months after inoculation.

68 Wassermann Reaction among Negro Insane of Alabama. R. R. Ivey, Tuscaloosa, Ala.

63. **Cure of Arthritis Deformans.**—On the basis that the presence of a septic focus in the seminal vesicles produces an arthritis, Fuller has performed seminal vesiculotomy 346 times with good results. Whereas in acute cases a cure of rheumatic complications following operation is rapid, it is natural in connection with chronic ones that the end result should be slower. In both phases of the disease, the operation, by draining the septic focus, puts an end to systemic toxemia. In the chronic cases, the toxemia may produce certain secondary lesions or results, which remain after the sepsis has disappeared, and it is not until these secondary lesions have vanished that a cure is usually reckoned. In Fuller's first series of thirty-five cases results were not as uniformly good as those attending later operations, for the reason that septic foci in these early cases were not treated surgically as radically as in the later operations. This was observed chiefly in connection with chronic cases which call especially for radical surgery.

66. **Polycythemia and Possible Relation to Duodenal Ulcer, Etc.**—The material studied by Friedman consists of twenty-five patients, twenty-three males and two females. The ages ranged from 19 to 57 years. All of the patients complained of the usual symptoms of chronic indigestion and of attacks of pain. The paroxysmal pain dated back mostly for years, and in a large number constant pain was also complained of. Many complained of night pain; some of hunger pain, others of both. A large number of them were users of bicarbonate of soda, which remedy they took at night on account of pain or on retiring in order to avoid night pain. Jaundice could not be elicited from a single history. Objectively there could be demonstrated in all the cases tenderness of different intensity to right of the epigastrium, in the continuation of right parasternal line somewhat above the navel; in but a few instances tenderness was found also somewhat to left of navel, and in one patient there was also tenderness in the appendicular region. In none of the patients was either liver border palpable. or spleen enlarged. or gall-bladder palpable. There were no tender spots characteristic for gall-stone disease or for gastric ulcer. Hyperacidity was noted in all, except for one case of hypoacidity and for another of heterochylia. The presence of occult blood could be demonstrated with the guaiac test only in a small number of cases, though with benzidin more frequently. A complete analysis of the feces of three patients showed pancreatic insufficiency. One of these cases came to autopsy and was proved to be chronic interstitial pancreatitis. Urine was negative, except for a large sediment of phosphates in some and transient glycosuria in two.

81. Relation of Teeth and Eyes.—MacWhinnie cites two cases to show that there is a very intimate relation between the teeth and the eyes. He insists that roentgenoscopy be made in all obscure eye troubles. In one case an abscess at the root of the left cuspid caused a very annoying eye trouble. In the second case there was an abscess at the root of the first molar which caused the visual disturbance.

British Journal of Children's Diseases, London

October, X, No. 118, pp. 433-480

1 *Two Cases of Chyliform Effusion. H. A. Lediard.
2 Four Cases of Relapsing Pneumonia in Young Children. R. R. Armstrong.
3 Case of Cutaneous Diphtheria. W. B. Jack.

1. Chyliform Effusion.—The first case cited by Lediard was one of chyliform ascites (tuberculous). The patient was 18 years of age. When aged 5½ an attack of abdominal pain first came on, resembling peritonitis, followed a month later by a second attack with similar symptoms, and recovery was associated with emaciation. At the age of 7 there was a slight threatening of the old abdominal pain. For the next eight years the boy was of delicate health. When Lediard first saw him the swollen abdomen contrasted markedly with a thin, pale face and limbs destitute of fat and poor in muscle. The face was expressive of prolonged physical depression rather than of pain, the disposition was quiet, the habits studious and the appetite capricious. The costal margin was much displaced by prolonged pressure from below, the abdomen was moderately tense and had a fluctuant wave all over. The anterior abdominal wall showed distended veins, and when he coughed fluid passed down the left inguinal canal into the scrotum. The enlargement of the abdomen had been remarked six years before Lediard saw him. Dulness on percussion was found for a limited area above the umbilicus; elsewhere bowel seemed to float above the fluid. Temperature was 101 F. There was no vomiting or cough, but diarrhea was a prominent symptom. The urine was free from albumin and sugar; bile-pigment was present in small amount, but no jaundice of the skin was noted.

From the history and from the physical examination a diagnosis of tuberculous peritonitis was arrived at and drainage of the abdomen recommended. Four days later visible pulsation of the heart was seen in the second and third interspaces, the liver was displaced upward, and the patient complained of the tightness of his clothes. On account of the rapid respiration and cardiac displacement, an incision was made above the umbilicus, with the result of striking a milk-white fluid at once. Six pints were removed and a drainage-tube inserted, but the abdomen was not explored. After the tapping fluid was not felt again in the scrotum, proving that the fluid was free in the peritoneal cavity. Abdominal drainage was instituted and death ensued three weeks later.

The necropsy showed that tuberculous disease was widely distributed throughout the body. The peritoneum, omentum, mesenteric lymph-nodes, liver, spleen, kidneys, lungs and brain all showed, either with the naked eye or with the microscope, a deposit of tubercle. As regards the lymphatic system in the abdomen, the receptaculum was apparently obliterated in a mass of glands and fibrous tissue, and the different lymphatics showed a very marked distention. Obliteration of the *receptaculum and evidence of dilatation of the lymph*-vessels behind the obstruction were the main features in the pathology, the morbid material was tubercle, and the method of chyliform ascites was by transudation. No perforation was found. Death was due to tuberculous infection of the membranes of the brain, after a long period, during which the disease was limited to the abdomen. The second case was one of chyliform ascites associated with Hodgkin's disease.

7. Liver Abscess.—In one case cited by Rolleston intrahepatic suppuration was evidently due to infection, conveyed by means of exploratory puncture, from a right-sided empyema. An exploring needle was inserted in the sixth intercostal space in the axillary line and in the eighth intercostal space in the line of the inferior angle of the scapula, but no fluid was withdrawn from these two punctures. Next day the trocar of an aspirator was inserted into the eighth space in the line of the inferior angle of the scapula, and in the sixth space in the posterior axillary line, but only a small quantity of blood and serum was withdrawn. From the fifth space in the anterior axillary line about 1 oz. of thick pus was aspirated with difficulty; it contained a Gram-positive coccus. At 8 p. m. 1 inch of the eighth rib was resected below the inferior angle of the right scapula and the pleura opened and solid lung was found; the wound was plugged. One inch of the sixth rib in the anterior axillary line was then resected, and about a pint of creamy, odorless pus was evacuated from the fissure between the upper and middle lobes. After this the temperature continued to oscillate between 103 and 97 F.; the pulse varied between 140 and 100, and the respirations between 44 and 24. It was obvious that there was retained pus although the discharge was free, but the patient's condition rendered further operative interference undesirable.

Death occurred from sudden collapse. A necropsy was performed. The right pleural cavity contained two distinct abscess cavities of which one had been drained and the other had not been opened. The liver, which weighed 4 pounds 12 ounces, was enlarged and was adherent to the diaphragm. Over the anterior and diaphragmatic surface of the right lobe there was an area the size of the palm of the hand projecting from the surrounding liver tissue. It was obviously an area of suppuration and showed a small puncture on a level with the fifth rib. Section revealed a large multilocular abscess, several of the loculi near the puncture being full of blood-clot. The puncture opened directly into a space containing blood-clot and pus. The second case was one of small latent solitary hepatic abscess in an infant.

10. **Bedbugs and Leprosy.**—A total of 105 bedbugs fed on lepers and thirty-five caught in the beds of lepers and examined by Thomson for leprosy bacillus gave no evidence that these insects harbor or transmit the disease. A further total of 107 bedbugs were examined as controls; twenty-five of these were caught in dwellings in Liverpool; the remainder were caught in the Spanish wards in Ancon Hospital in Panama. The controls also gave negative results. The Ziehl-Neilsen stain was used throughout. Full details of this investigation will be published later.

13. **Differentiation of Rheumatoid Arthritis.**—Though King admits that osteo-arthritis and rheumatoid arthritis may be due to infection, he says it is usually easier to trace this infection and certainly easier and more hopeful to treat it by vaccine in the latter than in the former. Among sources of infection pyorrhea alveolaris and gonorrhea are the most common. Auto-intoxication from toxins of the alimentary canal is also a potent cause. With regard to the affection of the temporomaxillary joints, King says it is an interesting point to notice that while it is frequently seen in rheumatoid arthritis, and almost always in the infective cases, and associated with spondylitis deformans, it is seldom seen in osteo-arthritis, in which spondylitis deformans alone is often met with. He suggests that osteo-arthritis should be differentiated from rheumatoid arthritis; that neither of these conditions should be considered a distinct disease, and seeing that either of them may be due to an infective process, it might be well to form a third group and speak of it merely as an infective arthritis.

15. **Arterial Pressure in Thoracic Aneurysms.**—From the result of treatment of forty patients Mackinnon is convinced that potassium iodid does not reduce the blood-pressure in aneurysm, although it relieves pain in many cases. Relief of pain can also be induced by other means, notably by the injection of sterilized solution of gelatin, a method of treatment first introduced by Lancereaux in 1904. Dr. Rankin, of the Seamen's Hospital, used this method in many cases, and Mackinnon had the privilege of examining the blood-pressure in these cases while undergoing treatment. In no single instance, however, had the gelatin any effect in reducing the blood-pressure, but there was very marked relief of pain in almost every instance where such symptom was a prominent feature at the commencement of the treatment. Mackinnon found that the blood-pressure in aneurysm is usually about normal. In about 65 per cent. of cases there is a difference in the pressure in both arms. In 30 per cent. of cases this difference is very marked and is a valuable aid to diagnosis. Reduction of the blood-pressure is a great relief to the patient and helps toward the cure. The lower the pressure, providing the pulse is regular and of normal rate, the better the prognosis.

38 *Glycogen Content of Mucous Membrane of Fallopian Tube. V. J. McAllister.

36. **Inversion of Uterus.**—The only treatment of chronic pathologic inversion worthy of consideration, according to Stark, is the removal of any tumor present and either hysterotomy or hysterectomy. Hysterotomy is the operation of selection when the patient is a young parous woman. It is contra-indicated and hysterectomy must be performed (1) if a malignant tumor is present; (2) if there is either thickening and hardening of the uterine wall or softening and atrophy of the musculature, and (3) if there are dense peritoneal adhesions binding down the uterus or fixing bladder or rectum. And finally, Stark concludes, if hysterectomy is decided on, the abdominal rather than the vaginal route ought to be selected for the performance of the operation.

38. **Glycogen in Tubal Mucosa.**—The material examined by McAllister comprised the fallopian tubes from twenty-nine gynecologic and obstetric cases of different kinds. The operations were for uterine rupture, fibromyoma, carcinoma ovarii, pregnancy complicated by fibroids, salpingitis, metritis, carcinoma of cervix, tubal pregnancy, pregnancy in a case of phthisis and ovarian cyst. McAllister found glycogen present in the epithelial cells of the mucous membrane of seven of the tubes examined. The first tube in which it was found was from a patient with metritis. The next case in which the tube mucous membrane was found to contain glycogen in large amount was one of extensive uterine fibromyoma complicating a five months' intra-uterine pregnancy. The glycogen appeared in the form of minute granules in the protoplasm of the epithelial cells and also on their free border lying in the tube lumen. In a case of carcinoma of the portio vaginalis uteri the endometrium was glycogen-free, the patient having ceased to menstruate a week previous to operation. The tube mucous membrane and the muscle fibers close to the lumen of the tube, as well as the lumen itself, showed its presence in considerable quantity. The cancer cells contained glycogen here and there in the form of minute grains.

In a case of uterine rupture at full term the mucous membrane and the muscular tissue close to the lumen of the isthmial portion of the tubes contained glycogen in considerable amount. The corpus luteum was glycogen-free. In a case of hysterectomy for fibromyoma the glands of the endometrium were packed with glycogen, while the tubes were glycogen-free. In a case of early tubal gestation, in which the plicae in the tube contained numbers of decidua cells, only a few of the latter showed mere traces of glycogen. Neither muscle fibers nor mucous membrane showed glycogen. In a case of uterine rupture at full term decidua cells found in one of the tubes (isthmus) contained mere traces of glycogen; the muscle fibers showed a good deal, while the epithelial cells of the mucous membrane were nearly glycogen-free. The isthmial tubes belonging to a two months' pregnant uterus showed no trace of glycogen. In an early case of salpingitis operated on a week after cessation of previous menstruation there was no glycogen in the tube except in the polymorphonuclear leukocytes.

In a case of carcinoma colli the endometrium contained some glands which showed considerable glycogen content, as also did the superficial epithelial cells. The majority of the glands were glycogen-free and so was the tube. In a case of hysterectomy for fibromyoma ten days after the cessation of the preceding menstruation the entire tube was glycogen-free. In a case of early isthmial tubal pregnancy with rupture, the ampulla epithelium contained much glycogen. The actual site of the pregnancy was not examined. The muscle fibers were also rich in glycogen. In a case of salpingitis with extensive infiltration of the plicae and presence of many plasma cells, operated on four weeks after previous menstruation, there was no glycogen present except in the polymorphonuclear leukocytes. In a case of tubal abortion and hematocele operated on two months after last menstruation the tube was glycogen-free. In a case of hysterectomy for myoma about three weeks after cessation of previous menstruation, the endometrium was typically premenstrual and the glands very rich in glycogen. The tube mucous membrane contained no glycogen, the muscle fibers a little.

In a case of salpingitis with intense infiltration, glycogen was absent, except in the leukocytes, where it was plentiful.

In carrying out this investigation McAllister had two chief aims in view, the first being to discover whether the mucous membrane of the tube ever contained glycogen and the second to discover whether, in the case of a positive finding regarding the presence of glycogen, the glycogen content was subject to a cyclic variation in relation to menstruation, as is the case with the endometrium. The first question he answers definitely in the affirmative, as in seven of the tubes examined glycogen was present in considerable amount in the cells of the mucous membrane. The investigation further shows that pregnancy is not essential to the presence of the glycogen. The second question requires further investigation but the results cause McAllister to state that undoubtedly the glycogen content of the mucous membrane of the tube undergoes considerable variations, and that, at a time when the endometrium presents all the signs of secretory activity and the epithelial cells of its glands are loaded with glycogen, the mucous membrane of the tube can be glycogen-free, and, vice versa, when the endometrium is free from the glycogen, the tube mucous membrane may contain it in considerable amount.

42. **Auricular Flutter.**—A man aged 62 came under Hay's observation with a large heart and peculiar arrhythmia. For ten years the heart had been known to be increased in size and occasionally irregular in its action. The auricular rate was 300; the ventricular 50 to 60, and coupled. A month later a 3 to 1 Cheyne-Stokes respiration and alternation of the pulse were noted. Large doses of digitalis produced a high grade of heart-block, but the auricular flutter persisted and is still present. The general condition of the patient is much improved. A small dose of digitalis daily is required to moderate the frequency of the ventricle. Hay has records of a man of 46 extending over a period of about seven years, demonstrating the presence of auricular flutter with a 3 to 1 ratio and occasional irregular action of the heart. When first seen alternation of the radial pulse was pronounced; this disappeared entirely while under observation. Later a 4 to 1 ratio was observed. Then in 1908 under the influence of squills the auricular flutter changed to auricular fibrillation, which in its turn gave way to a normal sequence of contraction. The heart continues to contract normally, and the patient, much improved, is earning his living.

55. **Radium in Treatment of Prostatic Cancer.**—Pasteau and Degrais comment on the extremely grave prognosis of cancer of the prostate even when removed at the first signs of trouble. The immediate results of the operation are bad and recurrence is the rule. Only about a dozen cases of prostatectomy for cancer were on record up to 1911, and the outcome of the operative cases since that date has shown no improvement. This being the case, the results of radium treatment seem to be particularly encouraging. They have applied it in fifteen cases of supposed cancer of the prostate. Two physicians were among the patients and these, realizing the gravity of their condition, displayed great perseverance in taking the course and the results in these cases were better than in any of the others. Material benefit was realized in every case, the more pronounced, the longer the course.

Three of the patients required an operation for rebellious cystitis later and in each the prostate was found materially reduced in size and of normal consistency. An illustrated description is given of the narrow tube holding the radium; the tube is pushed nearly to the tip of the catheter, just short of the opening near the tip. The radium should never be introduced with the bladder empty. They generally rinse out the bladder first and leave a certain amount of fluid in it. The radium is left in place for three or four hours, at intervals of from three to six days, suspending the treatment for nearly a month after five or six exposures. They reiterate in conclusion that there can be no question that radium has a positive action on cancer of the prostate. The exposures can be made by way of the rectum or urethra, or through an opening in the perineum or bladder. The cancer may be influenced to such an extent that the hitherto inoperable growth may be excised. The radium may at least arrest the tendency to hematuria and in favorable cases may cause the entire tumor to subside, the swollen lymph-nodes in the vicinity retrogressing also.

56. **Rectum as Receptacle for Urine.**—Lemoine reports a case of cancer of the bladder in which he implanted the ureters in the rectum after removal of the bladder, and then later made a new bladder by bringing down the sigmoid flexure between the serous and mucous membranes of the rectum, leaving the rectum free to serve as a bladder without contamination from stool. The lower end of the rectum was sutured to the bulb of the urethra. It thus emptied through the urethra and through a drain introduced through the perineum at its lowest point. The operation did not prove a success in the case reported, the sigmoid loop working up and the lower part of the rectum becoming necrotic so that the patient succumbed the eighteenth day. There was no trace of peritonitis, and Lemoine thinks the principle of utilizing the urethra in this way as the outlet for the rectum-bladder deserves attention.

73. **Emetine in Treatment of Hemoptysis.**—Flandin was impressed by the prompt disappearance of blood from the stools in cases of amebic dysentery treated by hypodermic injection of soluble salts of emetine. This suggested the possibility of the drug's proving effectual in treatment of hemoptysis, and the results have more than justified this anticipation. He applied the remedy by the same technic as for dysentery (compare The Journal, March 27, 1913, p. 917), injecting into the thigh 1 c.c. of distilled water containing 0.04 c.c. of emetine hydrochlorid. The result of the injection was surprising, the hemorrhage from the lung stopping immediately. No disagreeable sensation was experienced, no palpitations, dizziness or nausea. In some cases there was no longer a trace of blood in the sputum, but usually there are occasional blackish clots for a time. In the more threatening cases the hemoptysis may return and consequently he repeats the injection twelve hours later and once on the following day to a total of five. With the exception of one case of galloping tuberculosis, the tendency to pulmonary hemorrhage was definitely arrested in all his eight cases as also in twelve others in the experience of other physicians. He determined the arterial pressure before and after the emetine and was unable to note any appreciable change in this or in the coagulation of the blood or the blood-count. The measure seems to be entirely harmless and has succeeded when all others have failed.

76. **Chondrectomy for Emphysema of the Lungs.**—Roubachow traces the history of Freund's operation and tabulates the cases on record in which it has been applied. He thinks there is no doubt that when the chest wall loses its elasticity from hardening of the cartilages the lung does not expand and retract normally but persists distended and an emphysematous condition results. By mobilizing the chest wall, especially by resecting the costal cartilages, the wall regains its elasticity to a certain extent. Freund called attention as long ago as 1858 to the predisposition induced in the apex by degeneration of the first costal cartilage, rendering narrower the upper part of the chest wall. Degeneration of the cartilages lower down causes dilatation of the chest wall; in both types the wall loses its elasticity. Roubachow has found twenty-six cases on record in which chondrectomy has been applied with excellent results after intervals surpassing a year; also in twenty-five cases under observation for less than a year; in six other cases the improvement was only of brief duration; in four others there was improvement but it was not evident until after a certain period; in six cases no benefit was derived, and eight surgeons have reported nine fatalities.

77. **Primary Cancer of the Jejunum-Ileum.**—In about 40 per cent. of such cases the cancer develops in such a way as to obstruct the intestine earlier and more completely than with cancer of the large intestine, but this very fact enables radical treatment to be applied more promptly. In sixteen cases in which a radical operation was done before complete occlusion, thirteen of the patients were cured; the mortality was only 18.7 per cent. In ten patients operated on after occlusion had developed, only three were cured, the mortality being thus 70 per cent. Resection was done in twenty-six cases compiled here and analyzed from various points of view.

100. The Urea Index with Prostate Trouble.—Legueu states that he has calculated the urea coefficient according to Ambard's formula in 900 cases, and has found it of the greatest help in estimating conditions in the urinary apparatus. The findings throw light on kidney functioning and no other functional tests, etc., can approach it in the wealth of information it furnishes. The formula is based on the law that there is a constant proportion between the proportion of urea in the blood and the square root of the figure representing the amount of urea eliminated in the urine. (A previous article on the subject by Legueu was summarized in The Journal, May 13, 1913, and the formula was given in The Journal, 1912, lix, 229 and 818.) Taken in connection with the clinical picture and investigation of the factors of the dropsy-inducing nephritis, it proves a valuable guide whether to operate or not for prostatic disturbances. He cites a number of instances to show the importance of the information thus derived, the operation or the course of the cases confirming in every particular the correctness of the deductions based on Ambard's formula.

105. Easy Bacteria Count.—Rosenthal uses a centrifuge glass the tip of which is drawn out into a graduated capillary with a rubber screw cap. A drop of mercury is placed in the cap and the bacteria assembling in the capillary on centrifuging can be measured above the mercury. The method is approximately accurate and is particularly useful for comparing the bacteria counts between different diseases or cases or at different periods in the same case or from different cultures.

109. Diphtheria Bacilli in the Urine.—Freifeld states that diphtheria bacilli can still be cultivated constantly from the urine of a girl baby who had diphtheria at the age of ten months, six months ago. The diphtheric throat process was so mild that its true nature was not recognized but the bladder then became involved and there has been periodical expulsion of scraps of false membranes ever since. The bladder process is mild also; the vagina and urethra are not affected. He has not been able to find any record in the literature of this localization of a diphtheric process in the bladder mucosa. Diphtheria antitoxin was given when the bacilli were first found in the urine but it seemed to have no effect. Freifeld has examined the urine of ten other diphtheria patients and found the bacilli in the urine in four; the latest examination was made four weeks after the beginning of the diphtheria.

110. Deception in Tests for Vision.—Segelken was examining a man for a position requiring normal visual capacity. With one eye covered with a clean folded handkerchief which the man took from his pocket and pressed over the eye, the vision with each eye in turn seemed satisfactory. Segelken discovered just in time, however, that the folded handkerchief had a round hole cut through all the thicknesses, which were basted together.

119. Present Status of Transplantation of Organs.—Stich gives an interesting review of what has been accomplished in this line to date, his conclusion being that the matter is still in the tentative stage.

120. Hot Baths in Bronchitis and Pneumonia in Young Children.—Arneth emphasizes that air and more air is the imperative need in treatment of respiratory affections in young children. He also urges the extreme necessity of changing the position of the child every hour or so. The prone position aids mechanically in draining away the secretions as the pneumonic processes are usually most intense at the back of the lung. In treatment he has long made a practice of cold packs and baths but has changed to hot baths of recent years, finding them superior in every respect, especially for weaker children who chill readily at the surface while the febrile temperature accumulates in the center. The hot baths draw the heat to the surface, and he has never witnessed any injurious effect from their use. The higher the temperature, the weaker the child and the more defective the peripheral circulation, the more frequent the baths, up to five a day. With a temperature of 39 C. (102.2 F.) he gives the bath for ten minutes. The water is kept at 41 C. (105.8 F.) adding more hot water as it cools. These hot baths are easy of application while the temperature goes down under them to a remarkable extent. The reduction is most marked in thirty to sixty minutes afterward. A temperature over 40 or 40.5 C. (104 or 105 F.) does not contra-indicate the baths for infants or very young children, but with more robust and older children merely warm baths may be preferable.

He concludes the hot bath with a cool douche for which the conditions are extremely favorable as the back of the neck and chest are intensely hyperemic so that the reflex gasp can be elicited most readily. One nurse holds the child's head with both hands, protecting the mouth and nose against aspiration of water, and raises the child out of the hot water until the back of the neck is exposed; a second nurse then dashes a dishful of cold water fresh from the faucet over the back of the neck, just once. The child gasps for breath, exerting all the auxiliary muscles. It is then laid back in the hot water and the cold water is dashed on the chest. The whole procedure lasts only a few moments, after which the child is dried and wrapped in warmed clothes. No aftersweating is observed and the child is ready to eat. No unfavorable action on the heart was ever detected even with much debilitated infants. On account of the excellent action in every respect of the hot baths, he continues them once a day into convalescence if the child still coughs, even when there is nothing pathologic to be detected in the lungs. He makes a practice of applying the hot baths not only in febrile bronchitis, bronchiolitis and bronchopneumonia, but also in prophylaxis in cases of nasal catarrh, only that with this he refrains from the cold douche and wraps the child warmly to induce sweating. Omitting the cold douche, he applies the hot baths also in various affections of infants, with or without fever, when the peripheral circulation is defective. Great care must be taken that the child's bed is well warmed to prevent secondary loss of heat after the bath. In conclusion, he reiterates that the hot bath with the concluding dash of cold water must be regarded as a specific method of treatment for bronchitis and pneumonia in young children. It reduces the fever, acts as a revulsive and stimulates expectoration and deeper breathing, and thus prevents or puts an end to atelectasia and stagnation of the secretions, while it has a marked soothing, refreshing and sleep and appetite-promoting action and shortens the course of the disease. He gives a number of curves and tables to illustrate the effect of the hot baths.

148 *Results of Operative Treatment of Pleural Empyema in Children. F. Werner.

129. **Cyst in Femur.**—All but one or two of the twenty articles in this number of the *Zeitschrift* issue from Russian hospitals. In Bergmann's case a solitary cyst developed in the femur after an oblique fracture.

130. **Chronic Cystic Mastitis.**—Bertels states that he has encountered fourteen cases of this affection in the last three years and describes the history, findings and probable mechanism in these cases, in six others in his experience, and in six somewhat similar cases in men. A transformation into cancer was evident in seven of the female cases and in a few of the men.

132. **Operative Treatment of Epilepsy.**—The result in four of the eleven cases reported were extremely satisfactory. The epilepsy followed acute poliomyelitis in several of the cases. With the jacksonian type, there is little hope of benefit from the operation if it is delayed until the brain tissue has hardened at the spot and become atrophied. It is not always necessary to excise the nerve-center involved; in one of the cases complete recovery followed merely draining the edema of the arachnoid and making a valve-opening in the dura and skull to relieve the pressure, leaving the facialis center untouched; there has been no recurrence of the epilepsy since. The patient was a boy of 3½ who had been having up to eleven seizures a day following a fall eighteen months before. In the seizures the boy fell backward suddenly, lost consciousness, and there was first a tonic spasm of the right facialis and then clonic twitching, with spasms in right arm and leg, the seizure concluding with twitching in the left facialis domain and left arm and leg.

137. **Prostatic Hypertrophy.**—Engelmann tabulates the details of ninety-one cases in which he applied the Bottini technic and thirty-one with transvesical prostatectomy. In the first group 76.6 per cent. were cured and 11.1 per cent. materially improved; no effect was apparent in 3.3 per cent. and 8.9 per cent. succumbed to preexisting infectious complications. In the thirty-one prostatectomy cases, 80.6 per cent. were cured; 19.4 per cent. died but in only one case could the operation itself be incriminated in the fatality. In this case the bladder had been sutured at once and urine seeped out through the wound. In all the cases afterward he made a point of draining through the abdominal wound. The improvement in the total material has been permanent in all but three patients; these required brief catheterization anew years later. He advocates prostatectomy in all cases of severe infection of the urinary passages as it permits more effectual draining. If the kidneys are much diseased, however, a radical operation of any kind is contra-indicated.

140. **Incarcerated Hernia.**—Gussew concludes from analysis of his 420 cases of incarcerated hernia that the mortality can be reduced only by the more frequent restriction to local anesthesia, by improving the operative technic, by sending the patient to the hospital sooner, and by refraining from attempts to reduce the hernia by taxis. His mortality was 27 per cent. of the total cases and also 27 per cent. of the operative cases outside of those in which taxis had been attempted. An ascaris protruded from the wound the sixteenth day in one case, the patient a woman of 54.

142. **Volvulus of the Large Intestine.**—Jankowski devotes seventy-eight pages to this study of the prognosis with volvulus of the large intestine, as observed in fifty-three cases in the last ten years. The volvulus involved the cecum in five cases, the sigmoid region in the others. In the cecum cases the patients were men between 30 and 40; all were operated on and two recovered. The outcome in all cases of volvulus depends on the promptness with which conditions are corrected by an operation. When intestinal occlusion is diagnosed, he gives the patient a high oil enema and follows at once with a laparotomy if the enema fails to relieve. He generally siphons out the contents of the stomach, too. In twenty-four of his cases the sigmoid flexure had become twisted into a knot with the small intestine and only two of these patients survived. There was an interval of nearly four days before the operation in several cases and the intestine had twisted completely around, 300 degrees and more, thus injuring the wall beyond repair. In about half the cases there had been preceding attacks of pain in the region. In twenty-four cases the torsion was not over 180 degrees and 75 per cent. of these patients recovered. One in this group was 82 years old; the mesosigmoid was sutured to keep it from twisting again.

146. **Discolored Cerebrospinal Fluid.**—Schwarz emphasizes the importance of a yellow tinge to the cerebrospinal fluid in case of trauma affecting the head as it decides the question as to intracranial hemorrhage. Other features of the fluid may also point to the source of the hemorrhage. Xanthochromia may accompany other morbid conditions but it is of less diagnostic import then.

148. **Operative Treatment of Pleural Empyema in Children.**—Werner reports 178 cases of pleural empyema in the last ten years. The mortality was only 11.5 per cent. in the sixty-one idiopathic cases while it was 21.1 in seventy-one following

pneumonia; 33.3 per cent. in the six measles cases, and 38.5 per cent. in the thirty-nine scarlet-fever cases. The mortality was the highest with mixed staphylococcus and streptococcus infection. In regard to age, the mortality was 28.6 and 48.1 per cent. in infants up to 1 and 2 years old; it dropped to 19.6; 11.3, and 18.2 per cent. at the ages up to 5, 10 and 15. The operation was generally resection of one rib and drainage; the mortality after this was 15.9 per cent., while it was 17.8 per cent. in twenty-eight cases in which two ribs were resected. The balance is all in favor of the lesser intervention; healing was complete in only sixteen days in one case.

160 *Summer Diarrhea of Infants. (Sommerdurchfall des Säuglings und seine Ursachen.) A. Epstein.

149. **Acute Congestion of the Liver.**—Ortner found nothing in a man of 52 to explain the recurring attacks of severe pain back of the sternum and in the upper abdomen; it suggested intermittent claudication. There was moderate dilatation of the heart and signs of chronic mild myocarditis and mild arteriosclerosis; the urine was normal. While he was still puzzling over this case another patient applied with the same clinical picture, but this one stated that his attack of pain came on after climbing a hill. Ortner then had the first patient climb the hill and this brought on the attack. Both patients recovered entirely on staying in bed for a few days. During the attack the liver was found extremely enlarged, reaching from the fifth intercostal space to the umbilicus, the mechanical conditions amply explaining the pain back of the sternum. The urine was concentrated, with considerable urobilin. The same clinical picture was soon presented by a third patient; the paroxysmal attack following the test hill-climbing was so severe that the patient went to bed without returning to report at the physician's office. The whole trouble was evidently extremely severe acute congestion in the liver, and Ortner thinks that this is a wise effort on the part of Nature to relieve the strain on the weak right heart from the physical exertion. Nature drives the blood into the liver and relieves conditions in the heart as from a venesection, giving the heart a chance to recuperate.

151. **Acute Necrosis of the Pancreas.**—Haberer emphasizes the importance of the after-care following an operation for necrosis of the pancreas, insisting that the operation itself is a minor part of the treatment. We must bear in mind that the peritoneum with acute necrosis of the pancreas is far from normal, and it cannot be entrusted with the tasks usually imposed on it under other circumstances after an operation. The tampon and the drain should be left undisturbed much longer than in other conditions. The drain must be introduced at the lowest point without fail, and be merely packed around, the ends free, not covered with the tamponing gauze. He has had seven patients with acute necrosis of the pancreas; two were not seen until the fourth or fifth day and the pulse was good and not accelerated. He consequently assumed that the heart was not suffering seriously and that the patients would pull through without an operation, which proved to be the case. He advises this expectant treatment in all such cases not seen until late, but otherwise, under all conditions he advocates prompt operative treatment as this alone offers any guarantee of safety, whether the trouble is circumscribed or diffuse. An operation is also indicated in the advanced stages as a last resort when the pulse is much accelerated, showing the severe toxic condition. He emphasizes further the necessity for examining the biliary passages in all cases of necrosis of the pancreas and, in case a tendency to cholelithiasis is evident, the suitable operation on the bile apparatus should be done without delay, restricting it to what is absolutely necessary.

He reports the case of a young woman of 25 at the fifth month of her first pregnancy who developed acute necrosis of the pancreas. She was slender, the vascular system was normal, and alcoholism and syphilis could be positively excluded. She had been previously apparently healthy except for a mild attack several years before, now retrospectively diagnosed as a gall-stone colic. The diagnosis was obscured by uncontrollable vomiting and by pains in the appendix region. The pulse was accelerated, and the sudden collapse was ascribed to perforation-peritonitis of appendicitic origin. The median laparotomy, however, revealed the acute necrosis of the pancreas, and the gall-bladder was found clogged with stones. It was removed, while the pancreas was slit its entire length, tamponed and drained. The pulse kept high for a day or so, the temperature slightly above normal for a week, but the patient made a good recovery. The last of the drains was not removed until the end of the fifth week. The pregnancy was apparently not interfered with and seems to be progressing normally, now at the seventh month. Haberer has operated in five cases of acute necrosis of the pancreas but was able to save only two of the patients. In both these cases he operated at the same time on the bile apparatus.

155. Reviewed editorially.

160. **Summer Diarrhea of Infants.**—Epstein argues that a number of causes cooperate in the production of summer diarrhea, but admits that it is possible for infants to suffer from heat-stroke the same as adults. Excessive heat not only leads to the spoiling of milk but it produces favorable conditions for infections. At the same time, his own experience has been that with good hygiene the mortality need be no higher in the heated term than at other times. In reviewing his experience he states that during the year 1880, 35.5 per cent. of the 484 children who died out of the 2,978 admitted to the old foundling hospital in his charge, succumbed to intestinal trouble. In 1900 the new building was occupied, and at once the mortality dropped. In the thirteen years since, 820 have died of the 18,311 infants admitted; 27 per cent. of the deaths occurred January to March; 31 per cent., April to June; 22 per cent., October to December, and only 20 per cent., July to September. During the intense heat of July and August. 1911, only four infants died and none from gastro-intestinal trouble; two were feeble prematurely born, one died of erysipelas and the fourth from meningitis.

161. **Chloroform and Other Causes of Necrosis of the Liver.**—In the opening article in this "Borderland" journal, Fischler describes experimental and clinical experiences which confirm the assumption of the close connection—actual affinity—between the liver and the pancreas; injury of the latter involves also the liver cells. The liver is evidently the place where ferments are destroyed, especially trypsin. When more than the normal proportion of trypsin gets into the bloodstream, either from overproduction or lessened destruction, there is liable to be necrosis in the central liver cells. He states that in his experiments on dogs he always used chloro-

form with a little morphin and never had any trouble until in a recent series of experiments with an Eck fistula, twelve dogs died and in each necrosis of the central liver-cells was evident. He also reports the case of a man with a lymphosarcoma originating in a retrogastric lymph-node, the growth encroaching on the pancreas and leading to fat-tissue necrosis. At necropsy the central liver cells showed the same type of necrotic lesions as had been found in the dogs. No chloroform had been given in this case. These facts and other evidence presented demonstrate, he says, that exclusion of the portal vein cannot alone be responsible for the necrosis of the liver. Also that animals with an Eck fistula are not more susceptible to chloroform than others. Also that the susceptibility for chloroform is proportional to the repeated or prolonged administration. He insists that sufficient attention has not been paid to this point hitherto, and yet injury from the chloroform predisposes the liver to necrosis, although the latter can develop without chloroform. When it occurs with chloroform, it is merely the last straw rendering manifest the injurious effect of trypsin on the parenchyma of the liver; the liver yields when the various burdens and injuries imposed on it reach a certain limit. One practical conclusion from his research is the necessity for refraining from the use of chloroform when there is the slightest suspicion of abnormal conditions in the pancreas or in the liver. He mentions with approval that the Americans refrain from giving chloroform in pregnancy, assuming that it is liable to injure the liver. Practical experience has thus preceded the theoretic bases for this. He gives the details of his experiments, with colored plates of the findings in the liver.

162. **Movable Cecum.**—Hausmann states that there are various forms of movable cecum; the mesentery may be exceptionally long or exceptionally short. There is no characteristic clinical picture even when the anomaly is causing symptoms. The pains may be in the right half of the abdomen or in the epigastrium and the trouble may be confounded with almost any affection liable to cause pain in the right half of the abdomen.

164. **Local Predisposition to Apical Processes.**—Bacmeister succeeded in inducing in young rabbits conditions analogous to the abnormally narrow upper aperture of the thorax which has been incriminated in the development of apical tuberculosis. He passed a wire loosely around the upper part of the thorax, thus binding the animal's chest as it grew and increased in size, and the condition thus produced favored the development of an apical process when the animals were infected with tubercle bacilli. The apical process developed both by blood-borne and air-borne infection but only when there was already some old tuberculous focus elsewhere in the body. It is possible that the relative immunization in this case determines the character of the apical process. His research thus confirms anew the importance of an unduly narrow upper part of the chest as a factor in apical processes. whether it is the result of anatomic narrowing of the upper aperture or of the individual's stooping attitude, from habit or from the nature of his work. Tubercle bacilli finding their way into the apex are normally swept out again by the lymph-stream; the above mechanical conditions interfere with this lymph-flushing. The lymph-passages may also be obstructed by inhaled dust, and this likewise predisposes to the development of apical tuberculosis in the shoulder-bound.

165. **Spastic Contraction of the Stomach.**—Holzknecht and Luger give illustrated descriptions of sixteen cases of this kind and expatiate on the unexpected frequency of gastrospasm and the necessity for differentiating between it and hypertonicity of the stomach, which is accompanied always by normal or increased peristalsis. With gastrospasm there is no peristalsis. Hypertonicity always affects the whole stomach, while gastrospasm may be circumscribed. as with hour-glass stomach: regional, hitherto observed only in the pyloric and middle parts: or the whole stomach may be contracted. Gastrospasm may simulate the clinical picture of an ulcer while the radiologic findings suggest cancer, especially when the spastic contraction is confined to the pyloric region, in which case it resembles remarkably a ring carcinoma in this region.

The gastrospasm always entails great disturbance in motor functioning; the stomach may be evacuated with unusual rapidity on account of insufficiency of the pylorus (principally with duodenal ulcer, caustic corrosion of the stomach and duodenum and gastric phlegmon). In other cases the pylorus may be contracted so that evacuation is impossible. This occurs principally with disease in the bile passages and with the extreme hypertonicity in morphin cases. Gastrospasm can be best studied by roentgenoscopy or endoscopy, but the only means to differentiate it is by the changes in the picture observed at different times and by the subsidence of the spasm under the influence of atropin or papaverin. In one of the cases illustrated the spasm relaxed and the roentgenoscopic findings became normal during the ten or fifteen minutes the patient was being examined; in another case the subsidence occurred as completely but more gradually. In another case the stomach appeared normal; an hour later there was total gastrospasm; and this subsided anew in another hour. In four cases the findings were entirely different on different days. In other cases the spasm relaxed under the influence of atropin. In one instance the stomach did not empty itself for twenty-four hours, but under the atropin there was no residue after two hours. As the hypomotility in this case thus changed to hypermotility, although the gastrospasm still persisted to a certain extent, it seems possible that atropin acts electively on the pylorus and thus might prove effectual in treatment of abnormally long retention in the stomach.

170. **Induced Fluorescence as Aid in Radiotherapy.**—Krukenberg comments on the drawbacks of radiotherapy by the methods in vogue, especially that it is impossible to focus the rays on the actual point that needs them. Quantities of rays go astray in the adjacent tissues or are lost by the filtering required to prevent injury of sound tissues. Great advance would be realized if we could generate the therapeutic rays directly in the disease focus, and he thinks that this may be practicable. Of the substances which generate new light-rays when submitted to the action of the Roentgen or radium rays, those used in the fluorescent screen are available. Still more powerful is calcium tungstate ($CaWO_4$) which is insoluble in water, alcohol and physiologic salt solution, and thus is pharmacologically inert. Animals injected with this tungstate become luminous after exposure to the Roentgen rays. An intensively luminous spot appears in the rabbit ear after injection of a small amount of the tungstate followed by exposure to the Roentgen rays, and this spot persists brilliantly luminous for thirty days. The photograph of an animal that has been injected in this way shows an intense dark shadow at the site of the injection even as late as forty days afterward. Krukenberg injected into a mammary cancer 0.4 c.c. of calcium tungstate suspended in physiologic salt solution, after which the breast was exposed to the Roentgen rays (⅔ erythem dose) on three successive days. On the fourth day the breast was amputated. The tumor tissue showed marked processes of degeneration and necrosis in and around the point of the injection while nothing of the kind was evident elsewhere in the tumor. The intensity of the necrosis diminished with the distance from the site of the injection. Further trials of the method in rabbits with experimental tuberculosis demonstrated that the tungstate plus Roentgen-ray exposures seemed to have materially retarded the progress of the tuberculous process.

183. A Serum for Anthrax.—Detre announces the production of a *successful curative serum* for symptomatic anthrax obtained by immunizing a horse with cultures of the bacilli. Details of the development and use of the serum are given. The serum seems to be strongly bactericidal and contains agglutinins which agglutinate anthrax bacilli in very minute dilutions. This specific agglutinating power can be utilized in identifying the bacilli of symptomatic anthrax.

193. Immunity to Tuberculosis.—Hollos believes that, contrary to the *generally* accepted opinion, the children of the tuberculous inherit a certain degree of immunity. Children of tuberculous parents are more frequently affected than children of healthy parents simply because they are so much subjected to infection. Individuals are especially disposed to tuberculosis if their body cells are incapable of the production of immune bodies, and this is noticeably true of the children of alcoholics. *Symptoms of intoxication* show that the patient is capable of reacting and are also a measure of his sensitiveness to the toxin. When the organism ceases to react with such symptoms the prognosis is unfavorable. The more sensitive the patient is, the smaller must be the dosage of either tuberculin or immune bodies and the longer the interval between doses. If a patient under treatment who has not shown *symptoms of intoxication* begins to show them, this is evidence that the effort to arouse immunity is successful and that the organism is beginning to react, thus making the prognosis more favorable.

207. Wertheim's Operation for Uterine Cancer.—A table is given showing the clinical symptoms, microscopic findings and results in 100 cases of uterine cancer in which the operation was done by Wertheim's method. Two were cancer of the body of the uterus. *One of these has had* no recurrence for twenty-one months to date. The other has not been heard from. Of the carcinomas of the cervix, twenty-seven were mild and seventy-one severe cases. The primary mortality was fourteen; ten of the patients are in good health after *five* years; *fifteen* after three or four years and three after one or two years. Recurrence followed in twenty-three cases; thirteen have died since without local recurrence and there is no report from twenty.

222. Radium in Treatment of Cancer.—Latzko and Schüller describe with a colored plate of the findings seven cancer cases in which radium treatment was applied. The results, they state, justify the conclusion that if the exposures are made with all the precautions learned from the general experience with radiotherapy to date, the *radium therapy* is an inestimable advance in the treatment of malignant disease. Operable cancers should be excised, but in the inoperable cases, radium is liable to improve conditions to an extent hitherto considered impossible, bordering close on an actual cure. This result can be realized, however, only with the longest possible applications of the *largest possible* doses. The tissues after the exposures show the same changes as after corresponding Roentgen-ray or mesothorium exposures.

228. Bile in Direct Treatment of Gastric Ulcer and Hyperacidity.—The idea occurred to Glaessner that the benefit from a gastro-enterostomy may be due in part to the bile which finds its way into the *stomach through* the *artificial* opening. Experiments with bile and gastric juice both in the clinic, in the test-tube and on animals, confirmed this assumption. He found that the acidity of the gastric juice is modified by the bile and that it neutralizes the pepsin and thus *inhibits* the corrosive action of the gastric juice on a *gastric* ulcer. He gives the details of thirty-three *cases of* various stomach affections in which he administered small amounts of cholic acid as the equivalent of bile, from 0.4 to 0.6 c.c. of cholic acid. He generally *gave* it in the form of an emulsion of 0.2 gm. sodium cholate in 0.2 gm. oil, enclosed in a *gelatin* capsule, the patient taking from two to five of the capsules. Or he used in each capsule 0.1 gm. cholic acid or 0.2 gm. sodium cholate. Marked benefit was realized in a number of cases; in some the pathologic condition was transformed and the patients seem to be now permanently cured of their old stomach trouble connected with the hyperacidity.

234. **Operative Treatment of Thyroid Insufficiency.**—Von Jauregg says of thyroid grafting that this method of treating hypothyroidism has no present and has little if any future. But he relates a number of significant clinical and experimental facts which suggest the possibility that an operation on the thyroid—even when it is not enlarged—might have an influence on the functioning of the gland, diverting it into a more normal course. He thinks the method is worth a trial in myxedema with goiter, in endemic cretinism and infantile myxedema. If the thyroid is enlarged, part of it might be resected; if not, the isthmus might be severed, or both might be done in endemic cretinism as with this the isthmus portion of the thyroid is the part generally enlarged. Among the experiences related to sustain this suggestion is Poncet's success with exothyropexy in the case of a girl of 14 with typical myxedema. Her physical growth was scarcely that of a child of 8, and the mental development below this. The thyroid was abnormally small and he lifted it out of its bed and kept it exposed for a time, covered only with gauze. The wound was allowed to heal up after a month or so and the child developed much better afterward, the mental condition materially improving. This was also observed in Neudorfer's case, a complete transformation in character and in mental and physical development following an operation on a goiter in a youth of 19 extremely backward in both body and mind; similar benefit had followed an operation on a brother for goiter. Cathcart has also reported the subsidence of myxedema after partial thyroidectomy in a woman with a goiter. Von Jauregg has also observed a complete transformation after a partial operation on the thyroid gland in two dogs with pronounced cretinism and goiter.

238 *Causes of Psychic Abnormalities of Children. (Ueber die endogenen und exogenen Wurzeln der Dissozialität Jugendlicher.) E. Lazar.

236. **Recovery from Leishman's Anemia.**—Leishman's anemia has been regarded by most authors as an incurable disease. Caronia gives case-histories of eight recoveries, and cites six others, making fourteen in all. He believes, however, that the recoveries were due to natural immunity and the vitality of the organism rather than to any specific treatment. Various methods of treatment were used, the most effective being arsenical preparations, including salvarsan and cacodylate of iron.

238. **Causes of Abnormal Psychic States in Children.**—Lazar describes cases of various forms of abnormal tendencies in children, such as violence, sexual perversion, pyromania, exalted and depressed emotional states and criminal activities of different kinds. These may be the result of congenital predisposition or the expression of mental or nervous disease. But the fact should not be overlooked that even such abnormal tendencies may be overcome in many cases by bringing the child up in the proper environment. Treatment should be directed to early detection of the abnormal predisposition and to prevention of its development by rational training.

239 *Vaccine Therapy in Infectious Disease of the Urinary Passages. O. Wulff.
240 Advantages of Electrolysis in Treatment of Bladder Papillomas. R. Oppenheimer.
241 Egyptian Hematuria in Babylon. P. Richter.

239. **Vaccine Therapy in Urology.**—Wulff writes from the surgical clinic at Copenhagen in charge of Rovsing to laud the efficacy of autogenous vaccines in treatment of affections of the urinary passages. One hundred patients were given this treatment but only those of whom accurate and prolonged records were kept are discussed here. In one group of twenty-three patients the trouble began suddenly with pains in the loins, high fever, sometimes chills or pyuria. In the majority there had been recurring attacks like this for some time before the vaccine therapy had been applied. The acute febrile attack was arrested at one stroke by the vaccine, and the tendency to recurrence was cured at the same time. Wulff explains these cases as the result of some infectious focus outside of the urinary passages; when the bacteria from this focus get into the blood-stream from any cause this brings on the acute attack as the bacteria reach the kidneys and set up trouble there. After the invasion of the blood-stream ceases, the kidney trouble lets up, either healing completely or lapsing into a latent phase to flare up anew with new reenforcements of bacteria. The vaccine therapy puts an end to this, either by destroying the primary focus or by modifying the system in such a way that it is able to resist the bacterial invasion. He has had similar experiences with vaccine therapy of typhoid, but he has not been able to find in the literature any account of similar experiences with the prophylactic-curative action of vaccine therapy with infection of the urinary passages. The cure seems to be complete in twenty-one of the twenty-three patients in this group although their urinary trouble was of many years' standing in a number. In two of the cases the patients had recurrence of the trouble later, but in a much milder form and the tendency gradually abated entirely, the final effect thus being the same in all. In one streptococci had been found; in all the other cases the colon bacillus was responsible for the infection. This group included also four cases of pregnancy pyelonephritis. In two of the twenty-three cases, however, no effect from the vaccine therapy was apparent; the recurrence in these cases was always coincident with the onset of menstruation but no gynecologic affection could be discovered.

In a group of nineteen patients with a more chronic infectious trouble of the urinary passages, all were improved or cured but one. Albumin and pus disappeared from the urine but bacteriuria sometimes persisted. In the cases with kidney calculi or an infected wandering kidney, the outcome was, naturally, less favorable; only 53 per cent. of the seventeen patients in these classes were improved or cured. Excluding these groups, Wulff had 91 per cent. cured or materially improved of the other forty-six patients, while in a parallel group of forty patients treated with the ordinary measures, without the vaccine, only sixteen out of forty were materially benefited.

Albumin was found in the urine in 76 per cent. of the total patients before the vaccine therapy and the proportion dropped to 28 per cent. afterward; pyuria dropped from 100 per cent. to 41 per cent., but bacteriuria dropped from 100 per cent. only to 71 per cent.—showing that the effect of the vaccine therapy is less marked on bacteriuria than on the presence of albumin and pus in the urine. The opsonin index was repeatedly tested but was not found a reliable guide in any way in these urologic affections.

244 *Prophylaxis of Puerperal Fever. (Verhütung der durch Spontaninfektion verursachten Wochenbettfieber.) P. Zweifel.

244. **Prevention of Puerperal Fever.**—Zweifel states that at the gynecology clinic in his charge at Leipsic he has succeeded in materially reducing the number of cases of puerperal fever, and he ascribes this success to his method of wiping out with a dry sponge the clots left in the rear of the vagina and rinsing out the vagina with a fluid which restores the element lacking in pathologic vaginal secretions. This lacking element, he says, is lactic acid; it occurs in

the form of free acid in the normal vaginal secretions, to a maximum of 5 per thousand. With normal secretions and boiled water rinsing the vagina through a Fergusson speculum, the fluid is whitish, while there is a yellow tint when the secretion is pathologic. It is thus possible at a glance to distinguish the pathologic cases and commence the lactic-acid rinsing out of the vagina. He keeps up the prophylactic irrigation once a day for at least ten days. This lactic-acid method has been applied since 1909 to all pregnant women near term with a pathologic yellowish secretion, and the morbidity has dropped from 28.6 per cent. to 7.6 per cent. As nothing has been changed in the methods of procedure during this period except adding the prophylactic lactic-acid douche, the testimony speaks strongly in favor of the measure. He orders 100 c.c. each of (fermentation) lactic acid and of distilled water; 10 c.c. of the mixture to 1 liter of water gives the correct dilution of 5 per thousand. He suggests that as the lactic-acid douches have proved their usefulness, it might be well to introduce them generally without regard to pathologic conditions or not, just as the measures for prophylaxis of ophthalmia neonatorum are applied to all indiscriminately. This is the more rational as the 5 per thousand lactic-acid solution can never do harm. He warns against the danger of full baths just before delivery, and describes some cases in which severe puerperal fever followed for which no cause could be discovered except the penetration of the bath-water into the vagina. In one such case a woman took a bath in her boarding-house after the membranes had ruptured, just before entering the maternity, and severe puerperal fever followed, lasting for several months before the final recovery; no internal examination was made in this case and the perineum had been supported only with gloved hands wound with a cloth dipped in mercuric chlorid solution.

250 Therapeutic Pneumothorax for Out-Patients. (Sull'applicazione ambulatoria del metodo Forlanini nella cura della tubercolosi polmonare.) L. Cherubini.

249. Hemostasis in Operations on the Liver.—Tenani calls attention to the effectual prevention of any bleeding in resection of the liver by the technic he has worked out. His experiments were done on dogs and rabbits, and the results amply confirm the advantages of the technic for clinical use. He braids together four or five catgut threads, size 3 or 4, weaving them just loose enough to permit a needle threaded with catgut to be worked through at various points. The liver exposed, he cuts two strips of the braided catgut to correspond to the width of the liver where it is to be resected. One of the strips of braided catgut is laid across the top and the other across the bottom of the liver, just beyond where it is to be resected, and an assistant holds the four ends, thus drawing the strands of catgut taut across the liver above and below. The needle threaded with catgut is then passed through the lower strand, up through the liver tissue, and is drawn out through the upper strand. This is repeated at intervals of half a centimeter across the whole width of the liver; the loose ends are held two by two with forceps until all the loops are in place, when the two ends are knotted together over the support of the catgut braid both on the upper and under aspect of the liver. The organ is then cut across and there is no hemorrhage from the cut surface, nothing to require even the least tamponing. The catgut braid strips are left undisturbed and they gradually become absorbed without causing any disturbance. He drew the omentum down to cover the raw surface in his experiments, and he thinks this is an excellent adjuvant measure, as also his practice of injecting a small amount, not over 5 or 8 c.c., of liquid petrolatum. When the animals were killed the raw surface of the liver was found entirely healed with no trace of bleeding or infection. The petrolatum tends to prevent the development of adhesions while it is not a culture medium for germs like olive oil or similar substances, and it has no irritating action on the peritoneum.

257. Scarlet Fever.—Kramer reviews his experience at the Rotterdam contagious disease hospital with 910 cases of scarlet fever in the last four years. He states that in the last four months of 1912 there were 2,411 cases of scarlet fever at Amsterdam, with eleven deaths, while during the same period there were 358 cases at Rotterdam, with twenty-one deaths, the mortality thus being respectively 0.46 and 5.87 per cent. There was complicating otitis in 8.6 per cent. of his total 910 cases, and nephritis in 7.7 per cent. The diazo reaction was not found reliable in differentiation. In 2.1 per cent. of the cases the disease returned or relapsed, once during the second week after supposed recovery and in three, seven and five cases in the third, fourth or sixth week. Thirty-one "return cases" are reported. In five instances the scarlet fever developed after an operation, but in no case did the eruption appear first around the wound. One woman developed scarlet fever the tenth day after delivery; no source of contagion could be discovered. Kramer states in conclusion that he found epinephrin very useful in tiding the patients past the danger point when the adrenals seem to be suffering acutely from the infectious-toxic process. The most serious symptoms observed in the syndrome he attributes to the lack of the normal adrenal secretion, and he gives epinephrin to combat this. Camphorated oil, also, alone or in combination with the epinephrin, proved surprisingly effectual in some of the more serious cases. He does not give any details as to his dosage or technic with either the epinephrin or the camphorated oil.

NEURASTHENIA AN INCREASED SUSCEPTIBILITY TO EMOTION *

HOWELL T. PERSHING, M.D., LL.D.
DENVER

The neurasthenic is always with us, appealing to our sympathy, knowledge and skill to restore him to comfort and usefulness. His sufferings, however he may exaggerate and distort them, are only too real; his disability is often most serious. We are eager to help him, but his symptoms do not yield to the treatment which would relieve similar symptoms due to other causes, while the indications for general treatment are often vague and uncertain. If we knew the fundamental nature of neurasthenia and could direct all our treatment toward its correction, surely we could do better.

For more than twenty years a large proportion of my daily work has been with neurasthenic patients. The aggregate number of cases has been large, certainly more than a thousand, and each case has been carefully examined and studied, and the results have been recorded, in an effort to ascertain the causes and true nature of the disorder. I have not used the method of psychanalysis but I have made a special effort to encourage and assist each patient in telling his hidden causes of worry and fear. I wish to state certain conclusions from my experience which seem to me to be of great practical importance in making treatment more definite and more successful.

As the term "neurasthenia" has been used to denote nervous conditions accompanying very different diseases, it is necessary to define the class of cases to be discussed. Nervousness that is incidental to organic disease of the nervous system, or to an infection such as influenza, typhoid fever or tuberculosis, or to painful local disease, such as gastric ulcer or cystitis, should not be described as neurasthenia; there may be a neurasthenic condition but its importance is secondary to that of the major disease. If after the original disease is cured, however, a neurasthenic condition persists, it is to be regarded as a true neurasthenia. On the other hand, various effects of true neurasthenia must not be mistaken for the original cause. Disorders of digestion, of circulation, of vision, of micturition and of the sexual functions are often mistaken, by both patient and physician, for the original cause, when they are really only a part of the consequences of neurasthenia. A delimitation is also necessary on the side of the purely functional nervous diseases. The patient with incipient melancholia, paranoia or dementia praecox is often superficially neurasthenic, but the underlying condition is different in kind. Hysteric patients are generally neurasthenic, but their emotional crises are of a different type and they suffer also from suggestibility and restriction of the field of consciousness, causing paralyses, spasms, anesthesias or other stigmata not found in neurasthenia.

Neurasthenia, then, is a functional nervous disorder, not dependent on organic disease of any kind, not amounting to insanity, not hysteria, manifested by irritability, early onset of mental fatigue and a great variety of unpleasant and to the patient alarming sensations, chiefly in the head but also in various other parts of the body.

When we study these cases as to etiology, the idea of fatigue, especially mental fatigue, is forced on us. The patient's own story is usually clear on this point. Overwork in college, perhaps two years in one, or a full schedule of studies along with the struggle for self-support, is a common explanation. A merchant or professional man has worked long hours for years without a vacation; a mother has nursed an invalid child while carrying the burden of household cares, and so on. In a smaller proportion of cases without history of previous overwork, an illness, injury or mental shock seems to have caused the neurasthenic condition; but even here the condition, *once established*, is described as chronic fatigue; the patient has no relish for his work, cannot stand exertion, is always tired. Indeed, the existence and causal relation of fatigue generally appear so obvious as almost to justify the banal prescription, "You must drop everything and get away" (in Colorado it is "You must drop everything and get to a lower altitude"), a prescription by no means easy to take, although easily given, happily freeing the prescriber from troublesome care or the admission that there is anything beyond his scope.

A critical examination of the facts, however, will soon show that work and its consequent fatigue cannot be the fundamental factors in causation. When circumstances are favorable, the neurasthenic can often do a large amount of physical or purely intellectual work and actually be the better for it. Dr. Hall of Marblehead, Mass., successfully carries on a work cure for neurasthenics. Moreover, patients are commonly worse on Sundays or other holidays, and are often worse in the morning than in the evening. Of those who completely give up work only a small number seem to profit. Some are temporarily improved but relapse on returning to the usual conditions; many grow worse and worse the less work they do. Even rigorous rest in seclusion often fails and is sure to fail unless the doctor and nurse do far more than relieve the patient of exertion by ministering to his physical wants. The average neurasthenic does not get rested whether he works or is idle. Why not? Because his feelings of exhaustion were originally caused and are still maintained, not by work, but by emotion.

---

* Chairman's Address before the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

The essential fact about neurasthenics is that they suffer a far greater number of emotional disturbances of the harmful kind than average persons in similar situations. They are incessantly being annoyed, grieved and frightened. It is not that their emotions are extraordinarily intense; their greatest anger is mild compared with the savage rage of an alcoholic; their depression is not to be compared with the despair of melancholia; they are incapable of the passionate contortions of major hysteria; but innumerable, constantly recurring occasions, which would be of trifling moment to a normal individual, cause reactions of anger, fear or grief such as would be appropriate only to the few occasions which are really significant. The condition is like anaphylaxis. That part of the cortex in which emotional processes start has become sensitized so that perceptions or ideas, such as might occur in the normal brain with little or even no appreciable effect, excite a storm of outgoing currents to disturb and disorder all the functions of the body. This oversensitive condition of the emotional apparatus may also be described in the technical language of physiology as a lowering of the emotional threshold.

JAMES-LANGE THEORY OF EMOTIONS

The significance of this aspect of neurasthenia becomes clear when it is viewed in the light of the James-Lange theory of the emotions. Observation and reflection extending over many years have convinced me that, for the practical neurologist, it is a true theory, although the pure psychologist may be doubtful about some of its implications. According to this theory every emotion consists of three processes whose order is invariable.

1. The occurrence of the exciting perception or idea.
2. An action of the brain, excited by this perception or idea, which sends efferent nerve-currents to the organs throughout the body, causing a change in the action of the organs.
3. The return of sensory nerve-currents from the disturbed organs to the sensory areas of the cortex, causing a change in the sensations and a consequent perception of the bodily disturbance.

Take as a simple example the case of a person startled by sudden noise. The first stage is simply the perception of the sound; the second is the jerking of voluntary muscles, the involuntary cry, the sudden catch in the breath, and the jump of the heart; the third is the disagreeable sensations caused by these sudden changes in the body. In such cases the bodily effects and consequent unpleasant sensations are generally greatly in excess of what one would expect from the loudness of the sound. They may sometimes be useful in enabling one to escape from a sudden danger, but are generally quite useless and their exhausting effect is far greater, the duration of activity being considered, than that of any kind of work whatever. So it is with the various phases of anger, grief and fear in the neurasthenic. The exciting idea is generally not such as one would expect to have a marked effect, but it starts an emotional process whose second stage involves, directly or indirectly, every muscle-fiber and gland in the body, changing motion, respiration, circulation and secretion, while the third stage includes bad feelings which further alarm and depress. Biologically this disproportion of effect to apparent cause is explainable by the fact that the emotions are largely identical with the preservative and protective instincts, for which there is a predeveloped inherited mechanism, which normally in case of danger causes prompt and vigorous action toward escape, defense or attack, without waiting for reason to give its sanction. In modern life this mechanism is seldom useful, while its needless action, if frequently repeated, is always harmful. It is this primitive, inherited, powerful reflex mechanism which has become oversensitive and excessively active in neurasthenia.

NEURASTHENIA AND PSYCHASTHENIA

Apply these considerations to a typical case of neurasthenia and it is readily explained. Work may have something to do with it, for all work involves fatigue, and it is not to be denied that normal fatigue due to normal work tends to lower the threshold of the undesirable emotions and to inhibit the desirable ones. The effect of work alone is normally slight, however, and is quickly recovered from; a night's, or at most a few days' rest would insure recovery if the work were the only unfavorable factor; but along with the work are occasions for vexation, anxiety and alarm. The neurasthenic through heredity, disease or traumatism has a brain which reacts excessively to these occasions; to the moderate fatigue of useful labor is added the great fatigue of useless emotion; the neurons whose efferent impulses disturb the body become more sensitive, lowering the threshold still further; thus the daily number of emotional disturbances increases. The sensory centers of the cortex in which the emotion ends become more and more fatigued, so the resulting sensations become more and more unpleasant. This change in sensations, especially in those of the head, causes a feeling of changed personality which is strongly suggestive of mental disease, and thus the earlier fears of heart-disease, apoplexy or what not become relatively unimportant before the terrible fear of insanity.

Psychasthenia is also a lowering of the emotional threshold. Its difference from ordinary neurasthenia is in the nature of the exciting cause of the emotional disturbance. In ordinary neurasthenia the exciting causes are the exceedingly frequent occasions of grief, fear and anger, which are perfectly real but so slight that only the abnormally sensitive brain is harmfully affected by them. In psychasthenia the exciting cause of disturbance is merely the mental representation of a cause for emotion which for the patient does not exist at all, but which would be amply sufficient to affect a normal brain if it did exist.

Thus a psychasthenic girl passing a house sees some glasses of jelly exposed on a window-sill. The thought comes, "Some one might put poison into that jelly; what if I should do it?" The mere thought provokes such a feeling of horror that she goes home crying. A few weeks later, she takes part in a cooking-school exercise and is vividly reminded of the ideas concerning the jelly, but keeps control until one of the children who has eaten what she helped to prepare begins to complain of illness. Then the mere idea, which she knows to be utterly false, of having put poison into the food provokes a violent outburst of grief. All normal persons have some emotional reaction to mental representations which they know to be purely imaginary, as in reading fiction or seeing a play. Hamlet comments beautifully on the tears of the player who has been reciting the anguish of Hecuba:

When she saw Pyrrhus make malicious sport
In mincing with his sword her husband's limbs, . . .:

Is it not monstrous, that this player here,
But in a fiction, in a dream of passion,
Could force his soul so to his own conceit
That from her working, all his visage wann'd;
Tears in his eyes, distraction in's aspect,
A broken voice, and his whole function suiting
With forms to his conceit? And all for nothing!
For Hecuba!
What's Hecuba to him, or he to Hecuba,
That he should weep for her?

With normal persons, however, the knowledge that the conceit is imaginary always limits the intensity and duration of the emotional reaction. The theater-goer, the novel-reader, the day-dreamer may really tremble, shed real tears, or contract his muscles in righteous anger, but he restrains himself and quickly recovers emotional equilibrium. Not so the psychasthenic. His emotional centers are so oversensitive that a purely accidental image of himself as suffering a violent death, committing a dreadful crime or being insane arouses an intense horror. The intensity of the experience fixes it in memory; it becomes associated with almost everything, and the harmful emotion becomes habitual. The important fact in such a case is not the nature of the idea, or how it came into consciousness, or whether or not it has been repressed into the cellar of subconsciousness; these may have some importance; but the great fact is the physical condition of the cortex which permits such excessive and uncontrolled reactions.

TREATMENT

Whether the patient is simply neurasthenic or also psychasthenic, each excessive emotional reaction leaves a condition of instability which is a predisposing cause of the next disturbance; thus the disease perpetuates itself and he is caught in a vicious circle of cause and effect. How can he get out of it? Only by such measures as will temporarily lessen the number and the intensity of the emotional reactions and permanently change the condition of the cortex so as to raise the emotional threshold. The success of any of the innumerable remedies proposed is in proportion to the fulfilment of this indication, and this explains why apparently the same method is a brilliant success in the hands of one man and a total failure with others.

The founder of the rest-cure has always had a most extraordinary genius for reforming the emotional life of his patients. Those who employ what they conceive to be his method without some spark of this genius fail utterly and even make their patients worse. So it is with diet. Enough good food, preferably at short intervals, is essential; but it would be better for most neurasthenics confidently and cheerfully to commit all the dietetic sins possible at an average table than to eat in doubt and fear only the ideally perfect combination of foods. The same principle applies to work, exercise, travel, amusements and reading. They will be beneficial if they conduce to confidence and serenity, but harmful if they cause anxiety, fear or irritation.

The task of reforming the patient's emotional habits and restoring a normal balance and control in his cortex is both difficult and complicated. Every bodily or mental change in the patient has some direct or indirect influence which is favorable or unfavorable, but we must select such a combination of the possible favorable influences as will lead to success and at the same time prevent the unfavorable ones as best we may.

I find it convenient to analyze the problem of treatment as follows: 1. What can the physician do to influence favorably the patient's ideas, and thus control his emotions? This includes everything ordinarily denoted by explanation, suggestion and persuasion. 2. What can the patient be taught to do for himself in happily guiding his own mental processes? 3. What can the patient do in training his body to avoid injurious emotional reactions and favor the desirable ones? 4. What can be done by medicines and other agencies to improve the physical condition of the emotional centers.

1. *Influence of the Physician.*—Much may be done to displace false and depressing ideas by those that are encouraging and tranquilizing. This part of the treatment begins when the patient enters the waiting-room. No pictures of the dissecting-room or sick-bed, no specimens or surgical instruments should be there; all the furniture and decorations should be suggestive of comfort and peace. It seems trite to speak of the physician's attitude toward the nervous invalid, of the need of an interested, sympathetic, patient, confident manner. Yet only a few seem to realize how the patient is influenced by it. Something like "the insolence of office" is easily acquired in hospital and dispensary work; neurasthenics are trying patients and the physician easily slips into an attitude of indifference or exasperation. It is difficult to exaggerate the advantage of putting the patient at his ease in the very beginning and making it easy for him to tell his troubles and their real or imaginary causes.

In the anamnesis all the causes of fear and worry should be brought to light, not to magnify but to minimize their importance. I do not believe that these are concealed from the patient himself, but that through fear or diffidence he may conceal them from the doctor, and this is always an obstacle to success. Sexual troubles, whether real or imaginary, should be faced in order to remove them or to show how unimportant they are. The fear of insanity should always be uncovered and then lightly explained as one of the ordinary and almost inevitable symptoms of neurasthenia which does not indicate any real danger and is sure to disappear.

Then comes the physical examination, so careful and complete that the patient feels sure nothing could be overlooked, with reassuring words here and there as one organ after another is found to be sound. In summing up, much satisfaction should be expressed at finding the nervous machinery intact and ready to work well. It may be compared to a good automobile which needs only an adjustment of the spark or carburetor to make it work perfectly, or to an erratic watch which will keep accurate time when the balance-wheel is demagnetized. There must be no hedging in giving a favorable prognosis, but it should be understood that time is necessary to a cure and that after considerable improvement an apparent relapse is sure to occur, which, however, will be only slight and transient if the patient follows directions. The special examinations and reassurances must be patiently repeated as occasions arise. When the patient comes back discouraged and argues that he is no better and that his case is more serious than at first supposed, he really wants to be shown that he is wrong and hopes that the doctor will encourage him. In such cases a gain of a pound or two in weight or any other favorable indication may be quite sufficient to put him again on the right track. To agree with him or to be angry at his foolishness is to lose a golden opportunity.

2. *The Patient's Control over Emotions.*—The patient must be taught to avoid the occasions for unfavorable emotions. He is to shun all controversies, conversations about health or disease and writings on medicine or hygiene whether good or bad. He must absolutely cease studying his own case. His greatest difficulty will be in attempting to control his own trains of thought, especially when morbid sensations suggest them. To this end all harmless measures of diversion are to be cultivated, including both work and play. If reading has been abandoned it is to be resumed, for short periods at first, in spite of apparent bad effects which are due to fear. The patient must treasure up agreeable things to think about and be ready to take refuge in such thoughts whenever his bad feelings are most troublesome and other diversions are impracticable. In directing this part of the treatment a physician can utilize all that he knows of life in both sexes, at different ages and in the various classes.

3. *Physical Control by the Patient.*—With all possible care, nevertheless, there will be a residue of unavoidable exciting causes of harmful emotions. What can be done to minimize their effects? Each emotion disturbs internal organs which are beyond direct voluntary control, but it also has characteristic effects on posture, movement, expression of face, respiration and voice, all of which are more or less under voluntary control. By sufficient exercise of will on the part of the patient, therefore, an emotion, although already started, can be changed. Thus with a clear idea of what he wants to do the neurasthenic can substitute relaxation for tension, full regular breathing for irregular gasps, the expression of deliberate ease for that of anxious hurry, and an agreeable response for a sharp retort. In doing this he makes a great change in the sensations which constitute the third stage of the emotion; he to a considerable extent substitutes the sensations of courage for those of fear, of good humor for those of anger, and so on. But this is not all, the internal organs not under direct control of the will are favorably affected indirectly; thus, regular breathing tends to slow and steady the palpitating heart. It is by this process that we learn to overcome the habit of crying in childhood, that we are cured of stage-fright and that we learn to face trying situations of any kind. Note that it is a process, not merely of repression, but of intelligent substitution which can become habitual and be made to prevent even the violent paroxysms of major hysteria. The patient should be drilled especially in correct breathing, so that when he is threatened with a disturbance he can apply the remedy. Then let him start each day with the pious intention to show no fear or vexation in word or expression, still less in action, to make his breathing regular whenever it is disturbed and to keep his voice agreeably modulated and low pitched.

4. *The Use of Drugs.*—Application of the foregoing principles will greatly help all neurasthenics and for some it alone will be sufficient. We have patients, however, who, in spite of all explanations and encouragement, of all possible shelter from occasions for emotion and of honest attempts to practice the expression of repose, serenity and courage, are still habitually fatigued by emotional disturbances. The emotional centers are chronically irritable. They will gradually improve under the plan already indicated and whatever improves general health will help, but the process is slow In the meantime is there nothing to soothe these irritable centers and so enable the patient to prevent far more of the emotional reactions then he otherwise could? If you can assure him that there is, he will follow your directions with confidence and be more likely to succeed in the mental and bodily training.

The striking effect of certain chemical agents on emotions leads us to believe that in principle, at least, the emotions can be controlled chemically. Witness the depressing effect of the toxins of influenza and typhoid, the soothing effect of opium, and tobacco, the cheer of coffee and the positive exhilaration of alcohol and various ethers. Alcohol would be a priceless boon if its good effects could be secured and sustained without any disadvantage. It is a pity that its bad effects are so great and so certain. Tobacco and coffee may do some good without serious disadvantage, and I think it a mistake to forbid them to a neurasthenic already accustomed to them; but their good effect is not very great. Bromids, so valuable in epilepsy and so much used in various forms of nervousness, seem to me to make neurasthenia worse. The known relation of the internal secretions to emotion, of the thyroid substance to fear, of the testicular and ovarian substances to amorous feeling, and of the pituitary and possibly the pineal bodies to the sexual glands, warrants the hope that remedies of this kind may be of great use; but so far it is only occasionally that they are of service.

The one remedy whose effect is specific, highly beneficial and capable of being sustained without necessarily involving any serious disadvantage is opium. Far be it from me to encourage its needless or reckless use, but neurasthenia is a source of much unhappiness, often exhausting our resources to the uttermost. If it could be cured by a major surgical operation, the attendant danger of mutilation or death would not prevent the operation from being welcomed by many physicians and many patients. It is not wise to reject the most valuable drug now available, provided skill and care can make it safe. Surgeons do not limit themselves to blunt instruments because sharp ones are capable of doing harm, nor do they reject an operation because an unskilful or careless operator would make it a disaster. The following precautions must be taken: 1. Administration is to be only at regular times, never hypodermically but preferably in a capsule, allowing the patient no discretion to increase the frequency of the dose. 2. Other remedies should be combined with it, particularly strychnin and laxatives which will make trouble if the patient exceeds directions. 3. Every prescription should be for a limited number of doses and should carry a prohibition, printed or written in ink, against refilling without special permission. 4. The doses should be small at first, say 0.006 gm. (1/10 grain) of the extract of opium four times a day, and should be cautiously increased, always kept the smallest that will permit a fair degree of progress and later gradually *diminished.*

Used with these precautions, opium lessens irritability, fear and despondency in neurasthenia, just as it lessens cough and pain in other diseases, and by permitting emotional rest it gives the exhausted nerve-centers a chance to recuperate and greatly aids the patient in forming the correct emotional habits which he is being taught. I am sure that I have succeeded with it in many cases in which without it the difficulties would have been too great; I have never known a drug habit to follow its use in this way, nor have I had any difficulty in discontinuing it when it seemed best to do so. The dose need not be large; most patients do best when the maximum dose reached does not exceed 0.02 gm. or 1/3 grain of the extract. Only in a few desperate cases have I reached the larger doses such as would be suitable in melancholia, sometimes being rewarded by complete success, sometimes failing.

I know that many will think that in this discussion of neurasthenia I have treated slightingly or altogether omitted the most important factors, such as digestive disorders, ocular defects, defective elimination, pelvic diseases, sexual errors and so on. Any one of these factors may be of great importance on its own account or as a complication, but so far as the neurasthenia is concerned I regard them as secondary or incidental, one might almost say accidental. They have been disregarded in order to show more clearly and in their true proportions the essentials of neurasthenia.

Stedman Building.

ABSTRACT OF DISCUSSION

Dr. A. A. Brill, New York: Dr. Pershing is trying to reduce the conception of neurasthenia to some definite symptom-complex. He seemed, however, in the course of his discussion, to take in conditions which go beyond the scope of the definition with which he started. For instance, despondency and depression do not necessarily belong to neurasthenia, unless we take neurasthenia to include almost anything. I was especially interested in the statement that the symptom of fatigue in neurasthenics is more pronounced in the morning. In my own experience I have found that neurasthenics usually feel much better in the morning and become more and more fatigued as the day advances. On the other hand, patients with depression of the manic depressive type usually feel much fatigued in the morning and, as the day goes on, the fatigue wears off. I should be interested to hear some discussion on this point. If time permits, I should like to hear discussed the James-Lange theory as applied by Dr. Pershing to neurasthenia, which I must say I cannot accept. I was pleased to hear that Dr. Pershing included the mental element in the treatment, for to me psychic treatment is most important in neurasthenia. I would caution against the use of morphin in neurasthenics. I never use it in any of my cases.

Dr. Joseph M. Aikin, Omaha: I want to endorse Dr. Pershing's statement with reference to the symptoms of early morning fatigue. Until recent years I regarded that as more particularly a part of the clinical picture of melancholia, in which the depression is so much greater in the early morning than in the later hours of the day. I have, however, in the last three or four years been able to verify the particular symptom of which Dr. Pershing speaks. I am especially pleased that Dr. Pershing does not endorse the use of the bromids in neurasthenia. I have tried them out pretty thoroughly, and do not approve of their use in neurasthenics. Dr. Pershing also voices my experience in rejecting any form of opium whatsoever in these cases. I do not use a hypodermic on a neurasthenic, for any opiate at least, and I avoid, if possible, its employment for any drug whatsoever. There is something in the needle habit that we ought to avoid, even though there be nothing but distilled water in the syringe. What Dr. Pershing presented with reference to laxatives is in line with my experience in the treatment of neurasthenic cases. The less we prescribe laxative medicines or any drugs in the treatment of neurasthenics, the better our results. Intelligent direction as to quality, quantity, time and manner of taking food will give the patient more relief than drugs. If we can get these patients to eat a good variety of food and forget what they are eating, the necessity for laxatives will soon disappear.

Dr. L. Harrison Mettler, Chicago: If we are going to limit the term "neurasthenia" to mere psychic reaction of the emotional type, Dr. Pershing's presentation of the management of neurasthenia is most careful and practical. I am not ready, however, to accept the idea that all of the cases that I have minutely examined and conscientiously denominated neurasthenia are altogether psychic in character, the expression of merely an exalted affective psychosis. Remembering the elaborate and painstaking experiments of Hodge, Vas, Mann, and others in the laboratory, I have remarked a close similarity between the symptomatic revelations in the animals experimented on and the patients in whom I have made the diagnosis of neurasthenia. It is impossible for me to believe that emotional feeling is the basis of these animalistic revelations, as I am asked to believe that they are in the human being. Again, I have always noticed that in the incipiency of almost every infectious disease, long before the disease can be positively and definitely diagnosed, the clinical picture bears a remarkable similarity to that of the fatigue neurosis which we have been wont to call neurasthenia. Here I assume that the trouble is assuredly greater than a mere hyperemotionalism.

To sustain his position, Dr. Pershing adopts the James-Lange theory of emotion, wherein the feeling is said to follow, and not to precede, the cardiac, vasomotor and other disturbances. This theory I have never been able to accept. It is incomprehensible to me that a horrible sight, for instance, should cause the vasomotor apparatus to be disturbed and that this disturbance then causes the feeling of horror. The basis of the horror is not the mere thing looked at, but the ideas springing out of it. Without these ideas the sight would be wholly neutral and awaken no emotion. Once awakened, the emotion in its force and suddenness stirs the cerebral centers, and these reflect their disturbance on all of the organs of the body.

The James-Lange theory might apply in a way to the emotional states of neurasthenia as of any other disease. Abnormal conditions of the body always affect more or less the patient's mental state, but this is not what I understand that these authors intended to convey in their explanation of the emotions. At all events, if I am wrong about this, this application of the theory upholds my contention that neurasthenia is something more than a mere psychosis. I find the psychosis to be the result of some organic disturbance within the body in most of my neurasthenic patients. Psychotherapy alone, useful as it is in hysteria and other pure psychoneuroses, does not help me in the management of neurasthenics. I find that I have to resort to hygienic, physical and medicinal measures of all sorts to restore the patient's bodily health; then the mental state improves *pari passu*.

Dr. D'Orsay Hecht, Chicago: Although I am fully in accord with many of the views expressed by Dr. Pershing in his address, I must confess that I was anticipating something a little different in the attitude toward the general broad conception of neurasthenia as a disease entity. I had hoped to hear an expression of the same regret that I have felt for so long, that we, as neurologists, had too tenaciously clung to the view of neurasthenia as a distinct clinical condition. I, for one, am interested in the passing of neurasthenia as a disease *per se* in the sense in which Beard put it forth. I would even venture to add that, in my opinion, the whole tradition of neurasthenia as a primary condition of irritable weakness should have perished long before ever it was well on its way in medical literature. I have come to believe that in practically all instances of so-called neurasthenia a careful physical examination will reveal underlying pathology, perhaps not obvious pathology, but enough of organic change, however latent or subtle, to render the fatigue phenomenon explicable. If we look at neurasthenic individuals, moreover, as sick primarily in their bodies and not in their minds or their "nerves," we shall have gone far toward a better understanding of an asthenic symptom-complex. Hitherto we have put too much stress on the emotional values in these cases, and have seriously confounded them with the psychoneuroses, with which, I believe, they have little or nothing in common. I sometimes wonder if we are sufficiently careful to determine a small half-hidden focus of tuberculosis, which a tuberculin reaction might reveal. Again, I wonder if polyglandular insufficiencies are sufficiently appreciated to be held accountable for a fatigue syndrome. I wonder whether the rôle of faulty metabolism is well enough understood to be thought of in this same connection. Surely our increasing refinement in the field of serum and vaccine therapy should pave the way not alone for greater accuracy in diagnosis, but also for better success in the *treatment* of these patients, with their reduced vitalities, chronic, vague pains, nervous irritability and other evidences too familiar to recount. It is the physical diagnosis that I regard as important in the type of cases to which we refer, and the more keenly that we regard arteriosclerosis, latent tuberculosis and low grades of sepsis from one source or another, and what, for lack of a better term, we may call the toxemias of polyglandular origin, the less will be our provocation for making the diagnosis of neurasthenia.

Dr. Howell T. Pershing, Denver: I admit that any definition of neurasthenia is only approximate. I must also confess that I have occasionally made the mistake of regarding incipient melancholia, exophthalmic goiter or pulmonary tuberculosis as neurasthenia. As time has gone on, however, and I have done my best to perfect my diagnostic methods, so as to exclude all such conditions, there still remains a large number of cases of what in our present state of knowledge can be called only neurasthenia. Even the finding of some organic lesion does not forthwith exclude neurasthenia. There is a neurasthenic type of patient, with slight organic disease, who is quite different from the average patient with the same disease; the emotional disturbance is so out of proportion to the physical disorder that the neurasthenic condition must be dealt with on its own account.

I admit, of course, that neurasthenia, once established, has a physical basis in the oversensitive cortical centers, and that this may be aggravated by many morbid conditions in various parts of the body; but the essence of my contention is that exciting causes, which we are in the habit of regarding as purely mental, have far-reaching bodily effects, which not only aggravate but also originate and perpetuate the neurasthenic condition. That mere perceptions, mere ideas (the physical basis of which is purely cortical), do produce extensive and profound bodily effects is a matter of commonsense observation. Else, why should a piece of bad news cause sobs, tears, tremor, palpitation, arrest of digestion and loss of weight? Let us by all means study the physical condition of the patient from every point of view and improve it to the utmost. If we narrow our vision to the physical side, however, and do not improve the patient's mental habits we fail. In a case of nervous, that is neurasthenic, dyspepsia, you may wash the stomach, make the diet perfect and give any or all of the aids to digestion, with the result that the patient is still a dyspeptic and may be even worse. Leave the stomach alone, correct the emotional habits and you cure him.

PROGRESS IN PUBLIC HEALTH WORK *

GUY L. KIEFER, A.M., M.D., D.P.H.

DETROIT

The science of medicine has advanced more rapidly than any of its sister sciences. It is equally true that the science of hygiene has made more rapid strides forward than any of the other branches of medicine. Bacteriology and sanitary engineering have had much to do with the great progress of public health work. Most of the advancement has taken place in the past twenty-five years and its pace has quickened constantly during that period. Practical public health work, particularly as applied to municipalities, has undergone such a change that even to one intimately associated with it, the change is almost incredible. Let us take as a theme the analysis of the organization of a public health department and its work as it existed twelve years ago in comparison with the same organization and work to-day.

In 1901, on July 1, the board of health of a city at that time having approximately three hundred thousand inhabitants had a list of employees numbering twenty-four, and an appropriation to be expended in the work of $31,352. On July 1 of this year, the same department in the same city, which to-day has a population of something over five hundred thousand people, numbers its employees at 189, and has an appropriation of approximately $240,000.

The activities engaged in by the twenty-four employees of twelve years ago may properly be divided into the following subdepartments, or subheads:

1. An executive department manned by a health officer and a secretary.
2. A department of vital statistics, consisting of a registrar, one clerk and one night clerk.
3. A department of contagious diseases, consisting of two medical inspectors, two quarantine inspectors, a disinfector and a hospital for the isolation of small-pox patients only.
4. A laboratory in which a single chemist and bacteriologist was employed.
5. A department of milk and food inspection, consisting of two milk inspectors and two meat inspectors.
6. A plumbing and sanitary department, consisting of a chief plumbing inspector, five additional plumbing inspectors, one garbage inspector and one clerk.

All of these departments are still in existence, but have been so much enlarged that they can hardly be recognized. Besides the changes made in these existing departments, however, four new subdivisions have been added, as follows: a housing department, a smoke inspection department, a child welfare department and a department of publicity and public instruction.

It will be interesting now to discuss for a few moments the various departments as they exist to-day in comparison with formerly.

The executive department still has at its head a health officer, who is assisted by a secretary, a clerk and a stenographer.

The department of vital statistics, which is the backbone of every modern and up-to-date bureau of health, has had added to it a vital statistician and an assistant vital statistician. The duties of these officials are too well known to the members of this Section to need further comment. Allow me to say, however, that the board of health here described as it existed twelve years ago did not differ materially from many other similar departments, and that the registrar in the department of vital statistics was expected to keep records of births, deaths, contagious diseases and of everything recorded by that department, save possibly the issuing of certified copies of burial permits and other purely mechanical work of this kind. It occurs to me, and I feel that it should be emphasized here, that the first position to be established in the health board of a small city, or even of a rural community, after the appointment of the health officer, is that of vital statistician. Without careful bookkeeping of births and deaths, without careful accounting of the cases of contagious diseases, the work of the department must necessarily be handicapped.

The largest department in the number of employees and in the scope of its work is the division of contagious diseases, which has grown from a small beginning—the chief duty of which was to place placards and quarantine guards on houses wherein were cases of small-pox, scarlet fever and diphtheria—to a department, the duties of which are so manifold that they are difficult to enumerate and some of which should be grouped under the child welfare department. This department employs four medical inspectors, one chief medical inspector of schools aided by thirty physicians, eleven dentists, of whom four are inspectors and seven are operators, and twenty-seven nurses. Fifteen of these nurses are engaged in medical inspection of schools in the winter, and, to some extent during that period, they give attention to the prevention of infant mortality. During the summer months they devote all of their time to the latter activity, and twelve of them look after the houses in which there are contagious diseases, seeing to it that persons in such houses are properly instructed in the prevention of the spread of the given disease. These nurses take the place of the former quarantine inspector and disinfector, because they are much better able than that officer was to inspect the premises and to disinfect them when necessary, and above all, because they know how to give instruction in the prevention of disease. A number of clinics are included under this head, many of which are for the purpose of giving relief and aid to schoolchildren in whom physical defects of various kinds have been found, and to whose parents the correction of these defects has been recommended. There are five dental clinics, one nose and throat clinic, one eye and ear clinic, one children's tuberculosis clinic, besides a general tuberculosis clinic, a mothers' clinic, the object of which is the prevention of infant mortality, and a venereal disease clinic.

---

* Chairman's Address before the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Many health departments have under their supervision some sort of place usually designated by the public as a pest-house for the reception and care of small-pox; such an institution was maintained twelve years ago, and about six years ago a tuberculosis sanatorium was begun by the erection and maintenance of a small tent-house for the care of two patients. Since that time the sanatorium has been gradually increased until now it has accommodations for eighty-five patients. During the last five years the construction of a beautiful modern pavilion hospital for contagious diseases was started. At present there are completed and occupied, an administration building, a pavilion for forty cases of scarlet fever, and a similar one of equal capacity for diphtheria patients. Under course of construction are two additional buildings, one of which will accommodate at least fifty cases of venereal disease, and the other thirty cases of measles and twenty cases of various other contagious diseases in separate isolation compartments. Money is also available at present for the enlargement of the scarlet fever pavilion so that it may accommodate fifty additional cases of the diseases, and after the completion of all of these additions to the new buildings, together with the tuberculosis sanatorium and small-pox hospital, there will be a capacity of nearly three hundred and fifty beds.

The laboratory has had to be increased to meet the demands of the other departments. The chemist and bacteriologist originally in charge of this work has become the director of laboratories and there are two men busily engaged as his assistants, one of whom devotes almost his entire time to the analytic work that needs to be done in connection with the present department of milk inspection.

The division of milk and food inspection, which twelve years ago was manned by two milk inspectors and two meat inspectors, now consists of a chief dairy and milk inspector, ten assistant inspectors, one clerk and the two original meat inspectors. The change from "milk inspector" to "dairy and milk inspector" is not merely a change in name. In the early years the work done by these men consisted largely in the collection of samples from milk-wagons, many of them being dipped from the old-fashioned milk receptacles from which the retail peddler sold his milk. The necessity of such wagon inspection no longer exists because milk can be sold according to the improved regulation only in bottles. The collection of samples for analyzing has therefore been considerably simplified, and it takes the time of only one or two men to collect sufficient samples to keep track of the distribution of milk, especially since most of the work is done on the dairy farm. Inspections are made throughout the entire year of all of the farms from which milk is sent to the city, and the score card of the United States Department of Agriculture, Dairy Division, is used for this purpose. Whenever a farm is scored, a duplicate of the findings is left with the dairyman, so that he can readily see in which direction improvement is most necessary. A minimum score is required of him, and in this way the quality of the milk coming to the city has been much improved.

Meat inspection has remained to a great extent at a standstill because the solution of this problem is in the establishment of a central abattoir, in my judgment, owned by the city, and until this can be had, meat inspection cannot be made ideal, but must be continued because of the fact that some inspection, even though recognized to be imperfect, is better than none.

The department of plumbing inspection has grown so that now it has on its pay-roll a sanitary engineer, nine plumbing inspectors and two clerks. This department endeavors to pass on plans, so far as plumbing and drainage are concerned, of all new buildings, and to have the plumbing of these buildings inspected when it is installed, and reinspected when the fixtures are placed. Besides this the plumbing inspectors endeavor to look up all complaints of insanitary conditions due to old and imperfect plumbing, and have them corrected.

The housing department is the first of the new divisions and consists of a chief housing inspector and eight assistant inspectors. It is impossible in a discussion of so broad a subject to dwell at length on the necessity for this new activity. On the correction of housing conditions in any city depends to a large extent the reduction of its cases of sickness and its number of deaths. The plain object of such a department is to see that people have better houses in which to live, with more light and improved ventilation, and that they are taught how to keep such premises sanitary after they have been provided. Overcrowding of houses, and particularly overcrowding of sleeping-apartments, is one of the great causes of sickness and one that can be overcome only by a constant campaign of education, kept up by a large number of vigilant and intelligent housing inspectors; that the number employed by this department of the board of health is altogether too small is conceded, but some progress has been made in its growth from nothing to an inspection force employing nine men, and certain it is that the need of improvement of housing conditions has been recognized.

The smoke inspection department is manned by a smoke inspector and one assistant, who endeavor to prevent the emission of unnecessary clouds of black and dark-brown smoke from the chimneys, particularly of industrial institutions. It has been argued in the past that the cessation of smoke means the closing of factories and the lack of prosperity, but it has since been proved that factories of nearly every description can manufacture their goods in just as large quantities without smoke, certainly without so much smoke as to be a nuisance, as they can by the belching forth of quantities of thick, black, unconsumed carbon.

The child welfare department is made up of some of the activities that I have already enumerated under the head of contagious diseases, which should be classed separately. The medical inspection of schools, together with the dental inspection, the nurses that have to do with this work and with the prevention of infant mortality, the little mothers' league classes in the schools, the school-children's clinics, and the mothers' clinic, really constitute the department of child welfare.

Last in the enumeration of the new subdivisions I have placed the department of publicity and public instruction, and this from the point of view of its importance should be placed first. Public health work has come to be recognized as a campaign of education, and the more thoroughly such a campaign can be carried on, the better will be the results. The mere enactment of state laws and city ordinances of various kinds and the attempt at their enforcement with a big stick are methods of the past, and the instruction of the public in matters of public health and preventive medicine has taken their place. This department publishes a bulletin for the board of health, which gives the physician and public such instruction as is considered of the greatest value. It is allowable and quite customary to use the public press as extensively as it will lend itself to this purpose. Public addresses should be made, and are made by the various members of the staff, and in this city for the most part by the health officer. That this department is one of importance is seen by the fact that the American Medical Association has established a speakers' bureau, the object of which is to give the public anywhere instruction in preventive medicine and public hygiene. The calls for such instruction are becoming more frequent, and speakers are asked for all over the country. The result of such work is apparent, inasmuch as it can be readily seen that the public will give their cooperation to the enforcement of sanitary regulations much more readily if they understand them than if they are simply expected blindly to obey the law. In speaking of the department of publicity and public instruction, which has become a necessary adjunct in every bureau of health, I cannot help saying a few words about the public health nurse. Public speeches which are made at the request of a medical society, a civic organization, or a woman's club are of advantage in this work, but they do not compare with the good results to be obtained from the house-to-house inspection which is given by the public health nurse to the people who most need it. Persons of this class are not seeking this instruction and do not care for it, but it is brought to them into their homes, and by one thoroughly competent and one who gains their confidence. Were the attempt made to have physicians instruct persons, particularly mothers and fathers, or any adults, in private houses in the prevention of disease, it would be thought, even in this day of advanced preventive medicine, that the doctor was going beyond his sphere; in most cases he is still called to administer to the sick, and if possible restore them to health, and the instruction as to the prevention of the disease from which the patient is suffering must be left to some one else. This some one else is the public health nurse. Her activities should not be limited to the rendering of assistance to the medical inspectors of schools, to the instruction of mothers in the care of babies for the prevention of infant mortality or even to the instruction in the prevention of tuberculosis. There is no reason why the public health nurse cannot as well visit houses in which there are cases of other contagious diseases, for example, scarlet fever, diphtheria, etc. With our convictions that these diseases are spread by contact, either directly or indirectly, we have abandoned the old theory that it might be dangerous to have a nurse visit these homes for fear of spreading the disease; by giving the intelligent care to her hands and her clothing that she knows how to give, all danger is removed, and her work of instruction may be carried on so that it will reach all classes of cases. It has even been suggested—and the suggestion, in my judgment, is a good one—that the work of the public health nurse should be extended to include housing and sanitary inspection. In some of the smaller cities in Michigan, she has been clothed with the authority of sanitary officer and policeman, and the results obtained by her work have been excellent. This, of course, is again because she instructs first, and, only when absolutely necessary, prosecutes afterward.

Let us look for a moment at some of the results obtained in the work accomplished by a larger and improved health department in the city about which I am writing and see whether or not it pays. Taking from our mortality table the figures of some of the more important causes of death, we find that the mortality-rate from all causes for 1901 was 15.05 per thousand; for 1912 it was 15.42. The death-rate from scarlet fever was 24.3 per hundred thousand for the former year and 11.4 for the latter. For diphtheria, the comparison is 39 and 37; for tuberculosis 124 and 98; for typhoid 20 and 18.8. The only column in which we find an increase in the death-rate is under deaths from all causes, and yet when we consider the growth of the city and figure out the many additional reasons for deaths from all causes in a large city as compared with a smaller one, it will be seen that the actual increase is very slight. In each of the diseases mentioned, there is a decrease in the mortality-rate, and when we figure the actual number of lives represented by the difference in the mortality per thousand, we find that from these four causes alone, 212 lives were saved.

In comparing the infant mortality for 1901 with that for 1912, we are handicapped because births were not reported until a later date, or at least not universally reported, and, therefore, we can base the mortality of infants only on the deaths from all causes, and we find even with this improper method of calculation that for the former year 27.05 per cent. of the deaths from all causes were in infants under 1 year of age, and for the latter year only 25.6 per cent. Taking the infant mortality tables for 1906, the first year during which births were regularly and universally reported (because of the fact that the law imposed a penalty for failure to report and paid a stipend for the report), and basing the number of deaths on the number of births reported, and then comparing them with the same figures for 1912, we find that in 1906, 7,752 births were reported and 1,679 deaths, giving an infant mortality-rate of 216.5, whereas for 1912, the number of births was 15,252, the number of deaths 1,998, an infant mortality-rate of 131. In other words, had the death of infants continued for 1912 at the 1906 rate, there would have been 3,358 such deaths instead of 1,998, and the number of babies saved in the latter year over and above the 1906 rate is the difference between these figures, or 1,360. There can be no doubt that the progress made in public health work has been considerable and that money expended to keep pace with this progress is worth while.

EXPERIENCES OF A HEALTH OFFICER IN PORTO RICO *

ELMER F. OTIS, M.D.
PEÑUELAS, P. R.

William H. Taft, while President of the United States, once said:

> We have ground for national pride in the fact that England, France, Germany (not so much so) and Holland have been engaged in colonial business in the tropics for a hundred years, some of them for two hundred years; and yet it remained for American physicians (especially of the Army) to discover more things in ten years than were discovered in the whole two centuries before that time.

Porto Rico has been able to contribute a portion to the advancement along these lines. While the island was under military rule an example was given of what might be accomplished by organized effort. We are not to be surprised, therefore, that when civil government was first granted the sanitary work was instituted. It was not until two years ago the first of July that the service was organized as a separate department—with a former Army medical officer, Dr. W. F. Lippitt, at the head. At the next meeting of the insular legislature it was reorganized until it now compares favorably with those of the highest standard. At still the next meeting of the legislature, the past winter, the work was enlarged so as to include not only the campaigns against typhoid, tuberculosis, hookworm and mosquitoes, but an institute of tropical medicine was started. The purpose of this new law is to provide thorough instruction for the employees of the sanitary service, and also to educate and enlighten the masses.

A hospital for the care of contagious diseases and those who are suffering from special affections will be erected in each of the seven districts of the island. Health officials and insular doctors will be invited to come to these centers for demonstrations. It is also planned to give special courses in tropical medicine to these men and also to doctors from all over the world who may desire to study these diseases clinically.

The sanitary work is devoted to the following general lines:

1. Routine office duties.
2. Educational efforts.
3. Special campaigns against prevailing diseases, such as tuberculosis, uncinariasis, malaria and epidemics.
4. The Institute of Tropical Medicine.

In addition to the activities of the sanitary department, special mention might be given of the noble work being done by our *liga antituberculosis* in its persistent efforts against the white plague. The government authorities and best medical men are intimately associated with and second the efforts of its energetic officers.

The sanitary department, after summarily obliterating the plague conditions, at once began to wage a campaign against mosquitoes, even though yellow fever has never invaded our coasts since the American occupation. Malaria in certain districts of the island has been more than troublesome, however, and there is already a noticeable decrease in the number of mosquitoes.

Rat-proofing operations have been pushed throughout the several municipalities during the past year. Constant vigilance is exercised in order that we may not be surprised by an epidemic being brought to us, in case some other government may endeavor to hide the real conditions in order that its commercial relations may not be disturbed.

Antityphoid vaccinations are freely administered in every part of the island; while antirabic serums are given on the slightest possibility of the development of hydrophobia. Antidiphtheritic, antitetanic and antistreptococcic serums are available and freely used by physicians.

A special food and drug inspection department is one of our active agents for the safeguarding of the health and lives of the people. Almost daily confiscation of suspicious articles is reported. These articles are then sent to the special laboratory for analysis. Tons of spoiling or infected foodstuffs are sometimes refused a landing. Thus many deaths from toxemias due to poisonous foods have been eliminated. An annoying example of food adulteration was the placing of nitrobenzene in peanut oil as a flavoring, which resulted in sickness and some fatality.

ANEMIA WORK

Efforts against uncinariasis have occupied the attention of our leading men from the start. It can be truly said that, aside from pulmonary tuberculosis, there is probably no one thing that so stubbornly resists all medical efforts as the treatment of the hookworm anemics. The organization and results are effective; but the masses have not yet been able to see the necessity for putting forth the extra effort required, strikingly similar to experiences in tuberculous work.

Thus it is that, whereas at first almost every one was infected with worms, now about half of the inhabitants have been released by persistent medication and care. This simply shows what results may be accomplished in time if the efforts are well organized and the work is pressed forward. In my series of cases recently taken from children of the schools located in varying degrees of altitude and atmospheric humidity, it was revealed that the infection ranged from 13 per cent. in the low, dry barrios to 60 per cent. in the moist coffee plantations on the mountain sides.

SPECIAL EXAMINATION OF SCHOOLCHILDREN

Probably the next problem that will be taken up by the sanitary department will be that of the schoolchildren—the generation of the future. Already orders have been issued from headquarters instructing every health official to make a special study into the physical status of each child, especially as relates to the problem of anemia. While planning this work, I conceived the idea of broadening the scope so as to include a study as to the physical efficiency and defects of each pupil, since these strikingly affect their mental capacities. Accordingly, the study outlined as to the condition of each individual pupil examined was personally made—whether found in the town or the almost inaccessible country schools of the mountain region. By the use of the zero, minus, plus or double-plus signs, a fairly accurate representation of the physical findings was obtained in as short a time as necessary. They were taken in the following order, in tabulated form: age, sex, color, robustness, adenoid tissue, tonsil hyperplasia, teeth, vision, cataract, trachoma, pallor, percentage hemoglobin and examination of feces for ova of *Ankylostoma, Ascaris, Trichocephalus* and sundry other infestations. The observations outlined may be noted in the accompanying tabulation, while the details will be left to a fuller report after the work has been more thoroughly worked out.

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

PEÑUELAS SCHOOLCHILDREN

Total enrolment	1,134
Number examined	1,044
School sessions:	
Rural	18
City (town)	8
Percentage feces infested with hookworm ova	38
Maximum infested in one school	60
Minimum infested in one school	13
Percentage infested with other parasites	72
Maximum infested in one school	89
Minimum infested in one school	52
Average percentage of children showing evident pallor	54
Average percentage hemoglobin	81.5
Maximum hemoglobin	92
Minimum hemoglobin	35
Percentage defective teeth	67.5
Percentage tonsils and adenoids	84

Suffice it to say that one is strongly impressed at the overwhelming percentage of eggs found (other than those of hookworm); and that they seem to bear a certain relation to the uncinariasis and also to the degree of pallor. The large percentage of *Ascaris* is closely followed by that of *Trichocephalus.* Then came tapeworms, pinworms, distomas, flukes and amebas at times. One cannot but wonder if, after all, the worms represented by the large number of eggs that are to be found do not have a harmful influence, if only by their presence. It is not an unheard-of thing for an infant to pass a mass of roundworms as large as one's two fists, wriggling, squirming worms.

It has been well said, "It is readily conceivable that the animal parasites also may secrete [and I may also add "excrete"] toxic or otherwise active substances which are not without moment to their hosts." An important contribution on this subject was made by Dr. Flury. He has shown that "the tissues and excreta of these worms contain numerous compounds capable of inducing local hyperemia, inflammation and necrosis." Some of these extractives also produce a hemolytic action. This may perhaps help to explain why the color does not always quickly return when the ankylostomas are thoroughly expelled from the intestine.

YELLOW FEVER

Mention was made of our active campaign against the mosquito in order to prevent the possible invasion of yellow fever. The history of sanitation under our military government in Cuba was striking. Deaths from malaria dropped from 350 to 10 annually. At the same time the yellow fever did not so respond; and the natives began to talk of the superiority of their customs over the newly imported ideas on sanitation of the "Americanos." As soon as a certain mosquito, however, was discovered to be the carrier of the infection, the whole matter promptly terminated. In Panama, under military control, like results were obtained, but much more quickly.

The relative efficiency of the purely military to the civil form of government in sanitary matters is striking in those tropical possessions where the combination of determining factors is so diversified. It is generally conceded that the results obtained in every community from special sanitary work have been due to the fact that the authorities were given "a free hand"; this is in proportion to the extent that the leaders in the government think as medical men, and it is influenced in proportion to the political bias of those in power. Hence, the results accomplished under any civil government will be relatively slow as compared with those under military rule. It is indeed well that our government made its "records" before the Canal Zone is placed under civil rule. What was accomplished in three months in the Canal Zone (the eradication of yellow fever) it took three years to accomplish under the military protectorate of Cuba. Likewise a proportionately longer time will have to elapse before the "popular sentiment" of the Porto Ricans can be aroused to a realization of the importance of quarantine and rigid sanitation—although surprising results have already been accomplished for the amount of effort put forth.

While we feel thankful for the results already accomplished in Porto Rico, still we may expect even greater gains when we are assisted by the latest organization of the department and the beneficial effects of the Institute of Tropical Medicine, with its hospitals.

ABSTRACT OF DISCUSSION

Dr. J. W. Trask, Washington, D. C.: In studying the prevalence of diseases we are at times apt to overlook the fact that the number of deaths registered may in no wise show the prevalence of a disease; nor, for that matter, its real importance as a public-health problem. Take as an illustration malaria in the continental United States. The registration of deaths from this disease is in many localities quite undependable. In one state there were twelve deaths registered during a certain year. It developed, as a result of considerable correspondence, that in all probability not one of the twelve deaths had been due to malaria. The same thing is, in some measure, true in many other diseases. Often we cannot tell from the registered deaths the prevalence of a disease. Another illustration of this, familiar to you all, is small-pox as it exists in this country. It has of late years been a common experience to have recorded in the neighborhood of seventy-five or one hundred deaths from small-pox during the year. If we were to attempt to ascertain the prevalence of the disease from the mortality record it would be necessary to assume a known case fatality-rate, and if we took the rate which is common in most parts of the world, namely, 15 or 16 per cent., we should come to the conclusion that there had been in the country five or six hundred cases of small-pox, whereas, from the reports of cases we know that there had been from thirty to fifty thousand cases at least, and that the fatality-rate had been much below 1 per cent., and in some states as low as one-fifth of 1 per cent. We also get into difficulties and arrive at incorrect conclusions if we assume that we can take this general fatality-rate of, say, one-half of 1 per cent. as a basis to estimate the prevalence of the disease from the recorded deaths.

We know the fatality-rate of comparatively few diseases, and the probabilities are that in comparatively few diseases is there such a thing as a definite fatality-rate. The fatality-rates of many diseases vary with the season or locality and sometimes with the outbreak or other conditions not as yet known.

The registration of deaths is a necessity, for many and sufficient reasons, in every self-respecting community, but the prevalence of most diseases can be shown only by the recording of the occurrence of cases, for the occurrence of cases, not the deaths, shows the occurrence of the disease.

Dr. E. F. Otis, Peñuelas, Porto Rico: This question is a very important one to us; and for that reason we are trying. so far as possible, to get our laboratory to examine the patients before they die and to know in the central office what the diagnosis is—how many typhoids are found in a certain epidemic, and more especially, how many actual cases of malaria are found in a certain district by the microscopic findings of the blood-smears. Stress should be laid on the fact that in order to get results we must educate the people so that they may cooperate with us in our efforts to bring about sanitary reforms; because sanitation under legal pressure is slow and hard work. This is in contradistinction to sanitation under a military régime, so beautifully illustrated in the Canal Zone.

URETEROVESICAL CYSTS

AN OPERATIVE PROCEDURE FOR THEIR RELIEF *

JOHN R. CAULK, A.M., M.D.
ST. LOUIS

Ureterovesical cysts, cystic dilatations of the lower ureter or intravesical ballooning, a lesion, which in the precystoscopic days was considered more or less of an anatomicopathologic curio, is being more frequently observed and studied as time progresses. Until 1898 Englisch was able to collect but sixteen authentic cases, and Adrian, 1905, reported fifty-two cases collected from the literature. These observations were mostly necropsy findings or accidental discoveries during the course of vesical operations. Of the fifty-two cases which Adrian collected, only twelve were diagnosed correctly during life. Since the advent of the cystoscope and a more thorough training in the interpretation of cystoscopic pictures, this condition is becoming more generally recognized.

The literature seems to show that these dilatations are more frequent in females than in males. Englisch in his series reports ten cases in females and six in males. It may occur at any age, some authors stating that it occurs, as a rule, at a younger age in females that in males. Cases have been observed in patients ranging from six weeks to sixty-two years of age. In the opinion of some authors, these sacs, because they occur in the new-born, must frequently be of congenital origin, especially since they are often associated with other developmental abnormalities, such as faulty insertions of the ureter, double ureters, harelip, cleft-palate, etc. Others are even more emphatic as to the congenital nature of these cysts, asserting that, even though certain inflammatory conditions, such as changes due to the passage of a calculus and ulcerations, have been assigned as predisposing causes, the lesion, nevertheless, is always congenital. This assertion, however, impresses me as being too sweeping.

The cysts may be unilateral or bilateral. It seems certain that many of the cases are acquired and are secondary to inflammatory processes. Whether congenital or acquired, the two most important factors in the production of these formations are obstruction and the disposition of the ureteral insertion into the bladder. Congenital obstructions of the lower ureter are not particularly infrequent. In many cases they are considered to be due to a plugging with epithelium in fetal life or gluing together by exudates. The acquired obstruction may be due to inflammatory changes of the ureteral orifice secondary to the passage of calculi, to ulcers in its region, to ureteritis from a renal lesion, such as tuberculosis, or to contractions following faulty implantations after a ureterovesical anastomosis. The second factor, the manner of ureteral insertion into the bladder wall, is also extremely important. The ureter normally runs obliquely through the bladder wall and is protected throughout its intramural course by the firm bladder muscles, except for the short distance through which it passes under the vesical mucous membrane to end in its corresponding orifice at the side of the trigon. In cases in which this submucosal distance is long, dilatations of the lower end of the ureter seem more frequent, and, as a rule, the longer this distance, the larger the cyst; hence, if an obstruction occurs at such an orifice, it is easy to conceive how a sac will form following the planes of least resistance, namely, toward the bladder.

Such cystic dilatations may assume different forms and shapes, the most frequent form being that of a papilla with the opening of the ureter at its tip. Other forms, such as the triangular, finger-like, cherry-like, round and ovoid, have been described. The size may vary from a dilatation which is scarcely appreciable to one which may completely cover the trigon and extend down to the internal orifice of the bladder and cause symptoms of obstruction.

The ureteral orifice may open at any part of the cyst; more frequently, however, and especially in larger cysts, the opening is at one or the other side. The composition of the cyst wall has been the subject of some controversy. All authors are agreed that it is composed of two mucous layers, that of the bladder and that of the ureter. A controversy has arisen concerning the intervening structure. The majority of authorities have found only fibrous tissue between the two mucous surfaces; a few, however, have noticed muscle tissue. Stones have been reported within the cyst (Freyer).

The ureteral mons may vary in shape and size. As a rule, it is circular and constricted. In some cases it seems quite patent; in other cases it is blind. Englisch reports six cases of this type. Many cases of this kind have associated with them evidences of obstruction in the upper tract, hydro-ureter and pyo-ureter and hydronephrosis and pyonephrosis.

The symptoms of this malady are variable and indifferent; the small dilatations, and many of the large ones, may occur without producing any appreciable disturbances. The usual symptoms may be classified as vesical and renal. The relation of the cyst to the urethral orifice is the important factor in the symptomatology. If it does not impinge on the internal sphincter, it may cause no symptoms, except, at times, at the end of the urinary act, when there may be terminal pain due to pressure. If the cyst is large enough to interfere with the normal emptying of the bladder, the usual syndrome of obstruction may be present. Naturally, if cystitis intervenes, the symptoms will be magnified. The renal symptoms are those of obstruction, namely, of hydronephrosis and pyonephrosis. These complications are more liable to ensue in cases of double ureter. Cases have been reported in which the opposite ureter has been obstructed owing to a large cyst.

The diagnosis is, as a rule, simple and can be made definitely by the cystoscope, which reveals in the region of one or both ureteral orifices, protrusion and retraction of a cyst-like swelling with a smooth surface covered by mucous membrane ballooning at the efflux of urine and retracting at the end of the act. Ordinarily the orifice is visible, generally presenting some abnormality. However, this is not always so, as in the interesting case reported by Young, in which the ureteral orifice of the intravesical balloon was within a diverticulum. Such cystoscopic findings will easily differentiate a ureterovesical cyst from any intravesical pathologic lesion of which I am aware.

The operations done in cases reported in the literature have been of two kinds, the suprapubic and the endo vesical.

The suprapubic operations which have been described have been (1) splitting the cyst and suturing lengthwise the two mucous surfaces, as in Adrian's case; (2) the resection of the cysts with a circular suture of the two mucous surfaces; (3) the hernia operation described by Young and utilized in his case of a ureterovesical cyst

---

* Read in the Section on Genito-Urinary Diseases of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913

within a diverticulum. The endovesical operations have consisted in the splitting of the cyst at its ureteral orifice by means of a knife or scissors. Cases of this kind have been reported by Kelly, Pawlik, Albarran, Barringer and others. Results in some of these cases have been satisfactory. The objection to this procedure has been that recontraction of the orifice has been so frequent and rapid. Pawlik and Kelly mention this in their report and advise repeated dilatations similar to those utilized in cases of urethral stricture. Dilatation was done 112 times in Pawlik's case to prevent contraction.

I shall report six cases of well-defined ureterovesical cysts presenting some interesting features, which I have had the opportunity of observing.

Case 1.—Mrs. W., aged 39, was seen first in April, 1911. She complained of intermittent chills and fever, pain in the right kidney region, great vesical distress and marked asthenia. This woman had always been more or less of a chronic complainer. Her chief disturbance centered around her menstrual life, her menses having always been irregular, painful and profuse since their advent when she was 14 years old. In 1901 the patient had a placenta praevia. The fetus was removed and she suffered bad laceration of the cervix, which was later repaired. The patient said that in 1905 a doctor told her that she had a prolapsus of the uterus; for this she wore pessaries for four years. In 1911 a hysterectomy was performed and the conditions found at the operation were a fibroid uterus and cystic ovary. The patient reacted poorly after operation, had great trouble from her anesthetic, continued nausea, and marked weakness. On the twelfth day after operation a leakage of urine through the vagina was discovered. This continued for eight weeks. The patient in the meantime had developed a severe cystitis and evidently an infection in the right kidney pelvis. The diagnosis of a ureterovaginal fistula was made and a ureterovesical transplantation was done. The break in the ureter was found about ¾ of an inch from its lower end. It had resulted evidently from a ligature.

Following this operation the patient did fairly satisfactorily for about twelve days, when she began to have pain in her right side in the kidney region and developed irregular fever, chills and sweats. She was treated with urinary antiseptics, copious flushings with water and colon vaccine, as a colon bacillus infection was found. This time the patient left the hospital, went to her home in Wisconsin and remained there until the middle of October. The first part of her stay was fairly comfortable, but she was hampered more or less constantly by pain, chills and fever.

In September the pain in her side became more severe, the chills more frequent and the temperature ran higher. This time the patient began to develop symptoms of severe cystitis and gradually fell into a serious condition. She returned to St. Louis and consulted her surgeon, who found her in a very bad state, extremely weak and septic. She had a large mass in the right hypochondrium which was tender, and she was suffering extreme bladder distress. Her condition was so precarious that the surgeon deemed it unsafe even to attempt a nephrotomy, as she had reacted so poorly to former anesthetics and stood operation so badly. At this time I was called to see the case, and was asked if there was a possible chance of helping the process endovesically.

Cystoscopic examination showed an interesting picture. The bladder showed a general subacute cystitis, but the left ureteral orifice showed no important changes. The right half of the trigon was atypical owing to functionless ureteral orifice. Just above the region of the ureteral orifice a mass about the size of a large walnut was seen, which intermittently swelled and retracted. In the outer and upper part of this mass, when it protruded into the bladder, a small opening could be seen pointing directly to the right and ejecting small amounts of cloudy urine.

It was evident that the obstruction was mainly at the mucous membrane of the bladder, and I suggested to the surgeon that bladder drainage should be instituted in this place. For this purpose I passed a urethral speculum and then introduced a sharp hook. Next I introduced a spear, and then removed the speculum. The cystoscope was introduced and the balloon in the region of the orifice was caught with the sharp hook under the guidance of the cystoscope. This was given to an assistant and put on tension. I then pushed the spear through the orifice, and a large gush of cloudy material flooded and obscured the field. Pressure was made on the kidney in order to facilitate drainage. After the bladder was cleaned and refilled with clear solution, a knife was passed into the slit made by the spear, and two lateral cuts were made as deeply into the bladder wall as I felt safe in attempting. There was very little bleeding owing to the scar tissue. Following this, a ureter catheter passed easily and the renal pelvis and ureter were injected with collargol. A roentgenogram showed a large dilated renal pelvis about the size of a small orange; the ureter was markedly dilated and the stricture could be easily seen in the vicinity of the bladder. The ureter catheter was left in place in the ureter for lavage and for dilatation of the stricture. On account of vesical and ureteral spasm and the large dilated ureter above, the catheter stayed in place only about fourteen hours. This operation was done under cocain, and, after its completion, the patient felt greatly relieved. From that time on her pain ceased; the chills and fever disappeared in a few days, and she gradually improved. The urine after the one lavage of the pelvis became perfectly clear.

Realizing the danger of recontraction, we told the patient that she would have to have repeated dilatations. After this the orifice was dilated every three or four days; but, in spite of my attempts at dilatation, the ureteral contraction got ahead of me and there was still slight intravesical ballooning, so I decided to resect this whole area of obstruction and the cyst. The operation done was similar to the previous one with the exception that the balloon was caught with a small volsella and the resection was done with curved scissors This went beneath the mucous membrane and the specimen removed showed muscle-fibers.

The patient gradually regained her health. In fact, she felt better and was stronger than ever before. She gained 15 pounds in weight, attended to her household duties and to her social functions, and her only complaint was an occasional feeling of fulness in the right kidney region. She was again put on colon vaccines. She has been free from bladder symptoms and has had no fever since. I examined the patient by cystoscopy in June, 1912. At this time I found no intravesical ballooning. A No. 7 catheter passed easily. She still had a mild colon infection of her right kidney.

The cessation of symptoms was not due to the fact that the kidneys were not secreting, which Albarran has suggested is the cause of some of the cures, for I obtained urine of fair quality from this kidney, and a functional test of phenolsulphonephthalein showed it to be excreting one-half normal.

The patient remained perfectly comfortable until November, 1912, when she began to have some intermittent fulness in the kidney region, which was of slight consequence. The cystoscope at this time showed slight evidences of ballooning. The patient had a large ventral hernia, which her surgeon repaired. He also removed the kidney, which was small and atrophic, there being but slight pelvic distention. It was thought best to remove it as the patient did not want to run a chance of having any further trouble. She is now perfectly well.

Case 2.—Mrs. G., aged 42, complained of incontinence of urine, marked vesical distress and aching fulness in the right kidney region. The patient had been perfectly healthy until five years previously, when she was suddenly seized with an attack of pain in the right side. This was pronounced renal colic. Following this she passed a small, irregular stone; she remained well for two years, when she had a similar, but more severe, attack which terminated with the passage of a stone. She remained well until one year before I saw her, that is, two years ago. Then she began to complain of attacks of increased frequency of urination, trouble in starting the stream and pain at the end of the act. These attacks lasted for several days; they would then subside, only to recur. They became much more frequent. Two months before admission the patient suddenly had a retention, but finally voided with difficulty. Six weeks before I saw her she began to wet her clothes and also to wet the bed at night. Besides this she also had frequent desire to urinate, marked straining and tenesmus and voided but small quantities of urine. She passed no blood and had no chills or fever, but suffered from an aching sensation in the right kidney region.

On examination the patient seemed in good physical condition. Cystoscopy revealed an intermittent leakage of urine from the urethra and on close inspection a mass was noticed within the urethra about ¼ inch from the external orifice, which became larger and smaller. By stretching the urethra with a speculum a small opening at the tip of this mass was observed, from which the urine was escaping. A catheter was inserted and this mass was pushed into the bladder. The bladder was filled and had a normal capacity. The cystoscope showed a normal bladder wall. The left ureteral orifice was normal. On the right side of the trigon there was a long finger-like mass projecting toward the left side and extending down to the internal orifice of the bladder. This mass intermittently dilated and contracted. At the time of its dilatation it crowded against the internal orifice of the bladder. On the tip of this was a small irregular orifice of the ureter.

A procedure similar to the one utilized in the previous case was employed. The balloon was grasped with a tenaculum and given to an assistant. The curved scissors which had previously been inserted were then taken, and under the guidance of the cystoscope the whole balloon was resected, the denuded area being about an inch in diameter. There was some bleeding, but hot irrigation and epinephrin promptly checked it. Three days later a catheter was passed easily through the orifice. The patient in the meantime had been thoroughly relieved of her vesical distress. There was no leakage of urine, and the fulness in the right kidney region of which she had complained ceased.

Since the operation I have seen the patient on several occasions; she has been perfectly free from pain, and has had no incontinence. There has been no return of the ballooning and a No. 7 catheter passes freely. In this case I did not do a catheterization or functional test, as the operation was done at her first visit to my office.

Case 3.—Miss T., aged 42, was seen first in consultation April, 1913. She complained of increased frequency of urination. The patient had been perfectly healthy until several years previously, when she had an attack, somewhat similar to the present attack, which lasted a few weeks and subsided on internal medication. She was comfortable until a year ago, when she began to have markedly increased frequency of urination, voiding every fifteen or twenty minutes and arising three or four times at night. Her physician at this time found by cystoscopy a markedly ulcerated bladder which suggested tuberculosis; one ulcer was located around the right ureteral orifice. She had many specimens of urine analyzed for tuberculosis, but no bacilli were found. The trouble was pronounced a colon infection. The patient had no symptoms referable to the kidney.

The bladder capacity was 150 c.c. Cystoscopy showed a marked trigonal congestion with numerous ecchymoses, particularly around the left ureteral orifice and at the bladder dome. There was a healing ulcer about half an inch back of the right ureteral orifice. In the region of the right orifice there was a typical ureteral vesical cyst, which at its largest was about the size of a cherry. The orifice was small and situated at the tip of the balloon. The balloon pointed downward toward the midline. After much manipulation a No. 5 catheter passed through the orifice. The left ureter was easily catheterized with a No. 6 catheter. The kidneys were found negative, and the patient's physician is endeavoring to cure her cystitis. She has promised to return in order to allow me to determine if there is any dilatation of the upper urinary tract and later to resect the cyst if necessary.

Case 4.—Mr. Z., aged 26, single, complained of pain in the right side and increased frequency of urination. He had complained of this pain in his side for one week, but of the slightly increased frequency of urination for several months. By cystoscopy in May, 1911, I found a tuberculous bladder with ulceration around the right ureteral orifice. The right orifice showed a small intermittent dilatation which, at its largest, was about the size of a cherry. The orifice, which was irregular and scarred, pointed mesially, and a thick, ropy material exuded from it. A No. 5 catheter passed through the left orifice easily. The left urine was normal. The urine showed a normal phenolsulphonephthalein output. From the right side there was practically no secretion owing to the plugging of the catheter with pus. There were numerous tubercle bacilli. I did a nephrectomy two days later from which the patient made a nice recovery. Two months after operation there were no evidences of ballooning, but the orifice was flabby.

Case 5.—Mrs. M., aged 46, widow, complained of frequent urination. The patient sent to me for cystoscopic examination. She had a rectocele which her surgeon was about to repair. She had had no symptoms referable to her kidneys whatever.

Cystoscopy showed the bladder capacity normal, marked trigonal hyperemia, but no ulceration. The left ureteral orifice was normal. On the right side of the trigon there were two ureteral orifices. The upper and outer orifice was normal. The lower orifice blew out as a small cyst about the size of a cherry and then retracted to the bladder level. The orifice was at the tip and centrally poised. Clear urine was emitted slowly at the time of the ballooning. A No. 5 catheter passed through this opening, and a No. 6 through the upper opening. The lower catheter passed higher than the one which entered the upper ureteral opening. A No. 6 catheter passed easily into the left ureteral orifice. Urine from all three orifices was clear and uncontaminated.

The patient was advised to have a shadowgraph catheter passed and pyelography done; she consented, but unfortunately failed to keep her promise, and neither her surgeon nor I has seen her since. I cannot blame the cystoscopy for this, as she suffered no pain.

Case 6.—Sister M., aged 29, was sent to me by her surgeon for a cystoscopic examination and ureter catheterization. Roentgenoscopy showed a large kidney with many shadows and the patient presented a characteristic history of renal retention and vesical irritability. Her left kidney was enlarged and tender, and she had suffered from intermittent chills and fever.

Cystoscopy showed a general subacute cystitis. The right ureteral orifice was normal in appearance. On the left side of the trigon an intermittent ballooning was observed. This ballooning was pyriform, and when it protruded it ran obliquely downward and inward and followed the outer margin of the trigon for about half its distance. The ureteral orifice was small and irregular, was situated above and external to the cyst and was uninfluenced by the swelling of the balloon. From it projected a worm-like purulent mass. The orifice seemed to occupy a fixed position, the dilatation going below it. A No. 6 catheter passed with difficulty, but no urine could be collected owing to the thickness of the pus. Urine from the right side was normal and showed an excessive phenolsulphonephthalein output, 62 per cent. for one hour.

The patient's surgeon did a nephrectomy, but on account of my not having seen the patient since the operation I cannot report further regarding the cyst.

A summary of the features of interest in these six cases is as follows: The ages ranged from 26 to 46 years. Five of the patients were women and one was a man. Five of the cysts were located on the right side, one on the left side. One was associated with double ureter and seemed to be the only case which could be definitely classified as of congenital origin; the other five cases presented evidences sufficiently clear to allow them to be tabulated as acquired abnormalities. Of these five cases, one was secondary to a ureterovesical anastomosis; one resulted from inflammatory changes around the ureteral blood coagulum. This explanation seems to fit my second case. Noteworthy is the fact that all fatal cases of hemorrhage recorded in the literature, including my own, were observed in men, demonstrating again the greater resistance of women to loss of blood.

Therapeutically, internal remedies (stypticin, gelatin, epinephrin) are of little or no value. Tamponage of the kidney is practiced at Israel's clinic and has yielded there better definite results than secondary nephrectomy. Albarran[14] has abandoned intrarenal in favor of extrarenal tamponage, which he claims to be effective without possessing the disadvantages of the former method (sepsis, secondary hemorrhage in removing gauze pads). Removal of the bleeding organ is, according to the majority of authors, the safest method; it is the *ultimum refugium*, which, when permissible by the condition of the other organ, should be carried out without delay.

PERIRENAL INFECTION AND SEPTIC NEPHRITIS

Perinephritis of more or less gravity and extension may follow nephrolithotomy done on an infected stone-kidney. Perirenal infection, as a rule, starts in the wound, which, in spite of all precautions, will become contaminated with septic material from the incised kidney; rapidly the loose tissue around the kidney becomes involved and especially the indurated and poorly nourished fatty capsule offers a fertile soil for the infection, which in patients with low resistance may spread to the peritoneum. The most prominent symptoms of this septic peritonitis are marked meteorism and paralysis of the bowels. Albarran describes such a case[15] and I have recently made a similar observation.

Case 3.—Man of 33 with very severe right-sided and moderate left-sided pyuria; marked deterioration of function of right kidney. Characteristic calculi shadows in both kidney regions. Operation revealed horse-shoe kidney, with advanced pyonephrosis of its right half. No line of cleavage between both renal halves. Calculi of the size of olive-pits can be palpated in both halves of kidney just above the renal pelvis. Nephrolithotomy with drainage by rubber tube on right side; removal of calculus of left side by small pyelotomy incision.

The patient rallied well from the operation. During the first few days his temperature was about 99 F., his pulse between 90 and 100 and of fair volume, his general condition satisfactory; bandages were always very wet and several ounces of urine were removed from his bladder by catheter. On the fourth day meteorism set in, which increased rapidly. No bowel movement could be obtained in spite of laxatives and high enemas. Death occurred on the seventh day under symptoms of general sepsis (high temperature, rapid and small pulse, singultus, nausea, bronchitis).

Important items of the necropsy report are: Peritoneum hyperemic and covered with thin shreds of fibrin in a few places; transverse folds of small intestines in some places covered with grayish pseudo-membrane; hyperemic spots in cecum; both lungs contain many greyish-red bronchopneumonic spots in posterior part of lower lobes. Tissue around kidney shows hemorrhagic infiltration. Marked parenchymatous degeneration of liver.

A different result could have possibly been obtained in this case by primary removal of the pyonephrotic half of the horse-shoe kidney.

Graver than perirenal infection is that of the operated organ itself, which results in a septic nephritis. Albarran[16] gives a good description of the symptomatology of this condition (irregular temperatures, severe pyuria, general malaise, etc.), which almost always ends fatally under the symptoms of a systemic urosepsis. It is not advisable to lose valuable time with expectant or palliative measures (laxatives, diuretics, antiseptic irrigations, vaccine therapy). Removal of the diseased organ constitutes the only effective, and, in some instances, life saving treatment.

FISTULA

Nephrolithotomy for infected stone-kidney is, as a rule, followed by urinary fistula of shorter or longer duration. Such fistulas may, as every surgeon with experience in renal work will admit, occur in spite of faultless operative technic and persist many months, or even years. They are due to retention of septic material in the kidney or its pelvis, and to imperfect drainage. After the removal of one or more concrements from a pyonephrotic kidney, the patient is left with a constantly secreting, suppurating sinus which leaves him an invalid, makes existence miserable and may even be a serious menace to life. The healing of such a fistula that the patient has carried about for many years, is not infrequently coincident with total loss of the anatomic and functional value of the organ operated on, as in the following observation:

Case 4.—A man of 42 with bilateral pyonephrotic stone-kidney underwent left-sided nephrolithotomy over seven years ago, resulting in a suppurating fistula, which persisted more than three years, but finally healed spontaneously. At the first cystoscopic sitting after closure of the sinus, only a very small amount of urine could be collected from the left kidney, which, on examination, demonstrated the almost complete loss of function of that organ. On several cystoscopic examinations during the last three years no characteristic spurt was visible, nor could any fluid be obtained from the left ureter. The patient, though, is able to continue in his arduous business with his only functionating right-sided pyonephrotic stone-kidney.

While closure of postoperative fistula may follow expectant or conservative local treatment, secondary nephrectomy is, nevertheless, in many instances, the only effective means of relieving the patient from his distressing condition; it should be performed without too long delay, especially in cases in which the function of the remaining kidney is known to be satisfactory.

PYELOTOMY AND PRIMARY NEPHRECTOMY VERSUS NEPHROLITHOTOMY

It is thus apparent that there exist extended limitations to the general application of nephrolithotomy. The operation possesses obvious advantages (preservation of the kidney operated on, good view of renal calices and pelvis, comparatively small functional impairment). Its various immediate and remote untoward results, however, have gradually turned the tide toward other and less dangerous surgical procedures, for which the development and perfection of radiography and the various functional kidney-tests permit, at present, strict preoperative indications. Thus posterior pyelotomy has been advocated, of late, by many European surgeons as the operation of choice for the extraction of stones situated in or near the pelvis of aseptic or moderately infected stone-kidneys. In this country the attitude of most surgeons toward pyelotomy is more conservative. I recommended[17] the operation for suitable cases several years ago, and Eisendrath,[18] in a recent noteworthy publication, considers it destined to become an active competitor with nephrotomy in the majority of cases.

[15] Albarran: Ibid., p. 167.

[16] Albarran: Ibid., p. 166.

[17] Krotoszyner, M.: Trans. Am. Urol. Assn., 1908.

[18] Eisendrath, D. N.: The Journal A. M. A., April 12, 1913, p. 1145.

While pyelotomy is applicable only for the comparatively small group of aseptic and moderately infected cases, primary nephrectomy ought to gain more and more ground as the simplest, safest and quickest curative method for advanced pyonephrotic stone-kidneys in which the other organ is found to be functionally and anatomically intact. By being able to formulate preoperative indications for nephrectomy, the possibility arises of removing a pyonephrotic sac without opening it during the operation for inspection; thus quick closure of the wound is obtained and rapid convalescence and complete cure ensues. Bevan[12] reports improved results in his work on infected stone-kidney because he has recognized more than formerly the necessity of doing a primary nephrectomy. Kümmell[19] reports twenty primary nephrectomies for pyonephrotic stone-kidney without death, and among twenty-four nephrotomies for the same condition three fatalities and eight secondary nephrectomies. At Israel's clinic[20] the operative mortality for nephrotomy in infected cases was doubly as large as that of primary nephrectomy, 11 against 22 per cent. The indications for primary nephrectomy can, moreover, under certain conditions be extended to bilateral stone-kidney, especially in cases in which the burden of renal function is known to be carried by one organ only and in which the patient through a quicker and simpler operative procedure is at once relieved of an anatomically and functionally useless organ.

CONCLUSIONS

1. Nephrolithotomy is connected with serious immediate and remote untoward results.
2. It should be, wherever feasible, replaced by posterior pyelotomy.
3. Nephrectomy is the simplest, quickest and safest curative method for pyonephrotic stone-kidney, provided the function of the other organ is satisfactory.

THE IMPLANTATION OF THE URETERS INTO THE LARGE BOWEL *

CARL BECK, M.D.
CHICAGO

During recent years the problem of implanting one or both ureters into bladder, ureter or bowel has repeatedly been the subject of theoretical discussion and practical experiments, and conclusions have been drawn from the success obtained as to the possibility and expediency of this method.

The first one to undertake an implantation of the ureters into the intestinal tract was Simon, who in 1851 operated for an ectopy of the bladder by uniting the ureter with the rectal wall through a tight knot, which cut through and produced a communication between ureter and rectum. For two months the patient passed urine through the rectum, but then the anastomosis became very narrow, the urine escaped through the fistula, and the patient died.

In 1879 Theodore Smith of St. Bartholomew Hospital published in the hospital reports an account of a case in which he implanted both ureters into the colon; the patient, however, died. In 1891 Kuester of Marburg resected the whole bladder for a cancer and implanted the ureters into the rectum, also with fatal result. The first successful operation of this kind was performed by Chaput, whose patient lived for thirteen years. Gluck, Zeller, Bardenheuer and Novarro made experiments on animals. Morestin, Harvey Reed, Boari, Peterson, Martin and Zeit have all devoted a great deal of study to these questions in experimenting on lower animals as well as in operating on human beings.

There is, however, a great difference in operating on the lower animal and on man, since in the dog, for instance, the ureter is very small and thin and the bowel quite coarse, so that a union is not so easy as a similar union in a human being. Nevertheless a comparatively large number of good results have been obtained in animals and, though not a large number, several cases have been recorded in which the results of such transplantation in human beings have been successful. Chaput in 1910 records besides his own case, in which the patient lived for thirteen years, the case of Chalot's patient who lived for one year, of Guinard's who lived for five years, Michaud's who lived for two years, Auvray's for fifteen months, Boari's for six months, Fowler for three and one-half years, Peterson's for ten months, Beck's for seven months (which is, however, a mistake, since he lived eighteen months) and Martin's for eighteen months.

The indications for performing such an operation are rather rare. The principal indications are (1) injury of the ureter, in which it cannot be sutured again or implanted into the bladder, (2) fistula of the ureter, (3) painful cystitis (cystitis dolorosa, Trendelenburg), (4) total cystectomy (Kuester) and (5) ectopy of the bladder (Simon).

After Simon, Maydl has done more than anybody else to popularize the operation for the last indication, since he has had a number of successful results. But, on the whole, these operations have not gained an enthusiastic following on account of a great many drawbacks, principally the infection of the kidneys secondary to the operation and the difficult control of urination. Guyon and Albarran have shown, however, that an infection of the kidney does not necessarily follow an ascending infection of the ureters.

The methods of implantation of the ureters which have been used are mainly four:

1. After the first discovery of the bad consequences of the ordinary implantation and after Maydl's experiments a part of the bladder was taken along with the ureter for implantation, and good results have thus been obtained. This method, however, is not possible except in case of exstrophy and perhaps cystitis dolorosa.

2. The method of Chaput is the direct union of the wall of the ureter to the wall of the bowel. This method has been successful, but it is the one which endangers the union most of all. Peritonitis may follow this method very easily, since it is difficult to prevent a pulling out of the sutures by the action of the bowel or by infection.

3. Boari's method makes use of a small button, which is very similar to the Murphy button in its principle. A case in Giordano's clinic has shown, however, that concretions can form in that button.

4. The last method consists of the oblique implantation of the ureter into the bowel by a procedure such as Witzel has described for the oblique gastrostomy, sewing a catheter into the stomach-wall. Krinsky has described a method of oblique implantation of both ureters into the rectum with a flap-operation which is done by sewing

a flap of peritoneum and external muscle over the implanted ureter. Fowler has given us a method for flap-operation, in which the flap is made of the wall of the bowel.

The oblique method is one which I have used in my cases of implantation with this difference, however, that I have allowed the ureter to dangle with its free portion into the lumen of the bowel. I had the idea that the infection would be prevented by such a procedure, and, furthermore, that the lumen would not be included in a cicatrix of the bowel and therefore would remain patulous. I must say, however, that my first case showed that only one lumen remained patulous and that the other was very much constricted. It seems, nevertheless, that the portion of one ureter hanging down into the bowel has either become gangrenous or has retracted.

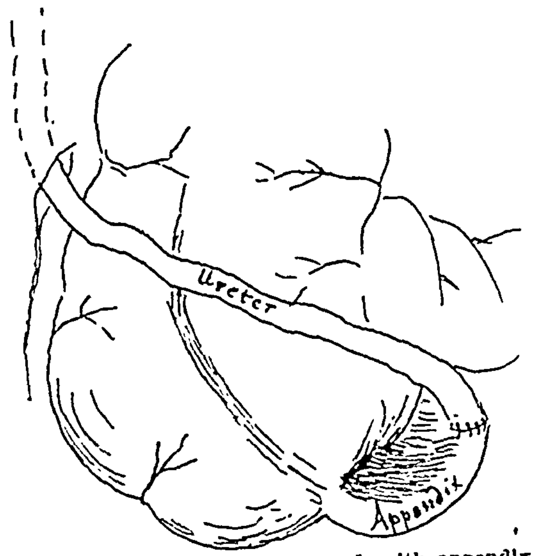

Fig. 1.—Ureter anastomosed with appendix.

The records show that the results obtained by various surgeons differ widely, and therefore the question, whether or not this operation is possible and expedient, is not yet solved. Each case bearing on the subject, whether successful or not, ought to be reported in order to give sufficient material for a decision as to whether implantation should be made use of or dropped. We have to consider this matter from two different points of view: first, with regard to the technical part and then with regard to the pathologic changes following the operation. If the ultimate result is unfavorable, we can call this operation only a palliative one which ought to be rejected, if the danger connected with it is in disproportion to the benefit which might be derived from it. In this case, though the operation be ever so simple technically, it will not acquire a place in surgery.

Unfortunately the above-mentioned consideration is often neglected, and a success is reported before the process of healing has ended. This, of course, perplexes the critical observer. Maydl's experiments were made years ago and certainly are the most important ones, because they were made by so careful and competent a surgeon. But his cases are throughout cases of exstrophy of the bladder of a particularly simple nature, his patients having been in good health in every other respect.

I will not enter into the details of the literature, but the description of two typical cases, which have been closely watched, may be welcome.

Case 1.—*Patient.*—A. F., aged 27, cigar-maker by trade came to me for the first time fourteen years ago in order to be treated for an obstinate disease of the bladder. He came from a family predisposed to tuberculosis (I had operated on his brother for a tuberculous fistula of the rectum) and had been weak from infancy. In early childhood he suffered from poliomyelitis, which caused a paralysis of one leg. When 20 years old he was operated on radically by Dr. J. B. Murphy for a pararectal abscess; a high dissection alongside the intestine, between bladder and rectum, had been necessary. It is not certain, but possible, that the affection of the bladder which I am going to describe originated from the rectal tuberculosis.

Present Illness.—Fourteen years ago the patient was troubled with a permanent strangury, which from time to time caused hematuria. The intervals between such attacks were sometimes but a few minutes. The examination of the urine showed a small amount of albumin and a great many pus-cells and led to the conclusion that there was a tuberculous cystitis. The cystoscopic examination gave a positive result. The bladder-wall was entirely covered with tuberculous ulcers. After a thorough reflection I advised drainage of the bladder above the symphysis, which was then done. When the cystotomy was made, the bladder proved to be badly infiltrated and without any active contractility; the walls were rigid and covered with tuberculous ulcers. I curetted the tuberculous masses thoroughly and drained the bladder for some time through a tube. The patient recovered visibly and for some months was in good condition. Gradually, however, all the bad consequences of a long drainage of the bladder appeared. The urine produced an obstinate eczema of the abdominal wall and of the scrotum, and the patient asked urgently for relief. I could not decide on recommending exclusion of the bladder, and I sent him for three months to the county hospital, where through rest and lying on the back he was cured of the eczema but retained his fistula. Finally I advised him to have the bladder excluded and the ureters implanted into the bowel, and this operation was done Jan. 10, 1899.

Operation.—I shall not enter into the particulars of a technical description, but I wish to state that I used a method which I had devised especially for this operation. I put the patient in Trendelenburg's position, isolated both ureters, cut them across not far from the bladder and on the right side implanted the ureter into the cecum, on the left side into the sigmoid flexure. The peritoneal covering of the bowel was removed with a flap of the muscular coat of the bowel, then the bowel was opened obliquely and the ureter was drawn far enough into the lumen with a thread to insure its dangling there. The opening of the ureter was made wide by slitting it open to one-quarter of an inch, then the peritoneal flap was carefully sutured over the implanted ureter. I

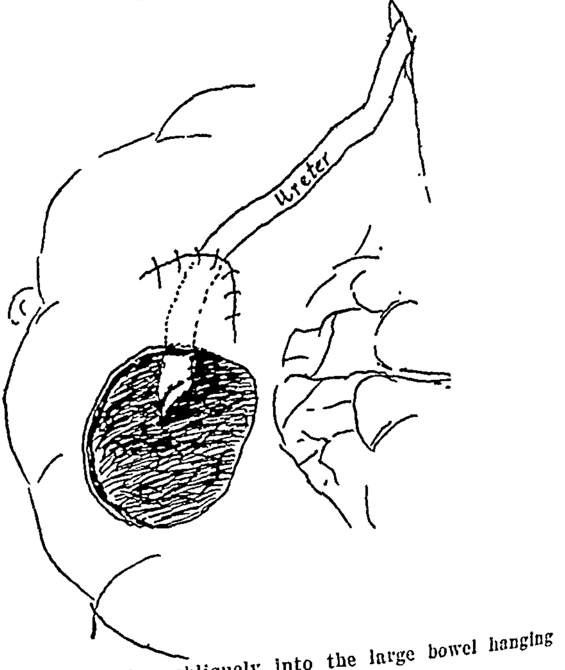

Fig. 2.—Ureter passing obliquely into the large bowel hanging with its free extremity into the cavity.

imagined that I could in this way avoid the two main drawbacks observed after all implantations, namely, stricture of the orifice of the implanted ureter and infection from the bowel; for the free ureter-end, the orifice of which had been obliquely split, could not shrink, and infection starts from the granulation at the spot of the implantation of the ureter into the bowel or at the stitch-holes.

Postoperative History.—My patient recovered after a rather long illness and was perfectly well from this time on to the day on which he entered the hospital again, that is, during a period of eighteen months. It was of great physiologic interest that the periods during which he could control the urine gradually grew longer and longer, that he did at times separate the discharge of feces from the urine, that he was able to hold the urine in the bowel during a whole night, and that the urine discharged was at times absolutely clear. During these eighteen months he had no trouble whatsoever which would point to an affection of the kidneys until precisely the time when he came back to the hospital, and even then the lung-trouble outweighed the kidney-trouble, so that till the end I was not sure whether he died from tuberculosis of the lungs or from tuberculosis of the kidneys.

The pathologic changes have been carefully examined, the case itself has been closely observed clinically and post mortem, and the observations made might be of use for the determination of the question, when, if ever, a transplantation of the ureters is indicated.

Necropsy.—Patient is emaciated; his panniculus has disappeared almost entirely. An opening of the head has not been permitted. Mouth and pharynx are absolutely normal; so are the larynx and the trachea; in the trachea masses of bloody, colored mucus are found. Both apices of the lungs are emphysematous and the pleurae of both sides are totally adherent to the chest-wall. The right lung is permeated with old tuberculous scars and callosities and the left lung shows many symptoms of a recently rapidly progressing tuberculosis. Some of the caverns are connected at points. The abdominal viscera show the most interesting changes. The liver is hypertrophied and amyloid, the gall-bladder very much dilated but otherwise normal. Stomach and intestine show no sign of tuberculosis, not even in the part through which the urine was flowing. In the region of the sigmoid flexure are hard peritonitic adhesions, which date from the operation. The kidneys show the worst changes. Neither of them can be palpated, because the entire fatty capsule is badly infiltrated, and even after a slight dissection it is evident that both kidneys are surrounded by an extensive peritoneal exudate with multiple abscesses. The pus is yellow and thick and shows the signs of a cold abscess. The right kidney is partly normal; on other parts it shows macroscopic changes of acute and chronic inflammation. On this side the ureter and the pelvis of the kidney are fairly normal. The left kidney is almost entirely transformed into necrotic tissue, so that the normal borders of the kidney and the pelvis can no longer be discerned. The ureter of this side is much distended and following it up to the bowel we see that the orifice is almost obliterated. The sigmoid flexure is open in the region where the ureter has been implanted, and, besides a few very small tuberculous and cheesy degenerated lymph-nodes, does not show any symptom of tuberculosis or any sign of irritation. The mucous membrane of the bowel is not normal in appearance; in color and luster it looks rather like the mucous membrane of a bladder. The right ureter is still dangling free down into the lumen by one-quarter of an inch. The projection of the left ureter has disappeared and the opening can be found only with difficulty with a fine sound. At its orifice are concretions of urates. The bladder seems to have shrunk entirely and is contracted to a small nodule almost without any lumen. The microscopic examination of both kidneys, so far as the tissue could be plainly discerned, shows, besides an amyloid degeneration, a bad infiltration of the interstitial tissues with quantities of bacteria and cocci. The microscopic examination of the ureter shows no tuberculosis. The microscopic examination of the bowel below the place of the implantation shows a strange transformation of the epithelium into a pavement epithelium very much broken up on the surface.

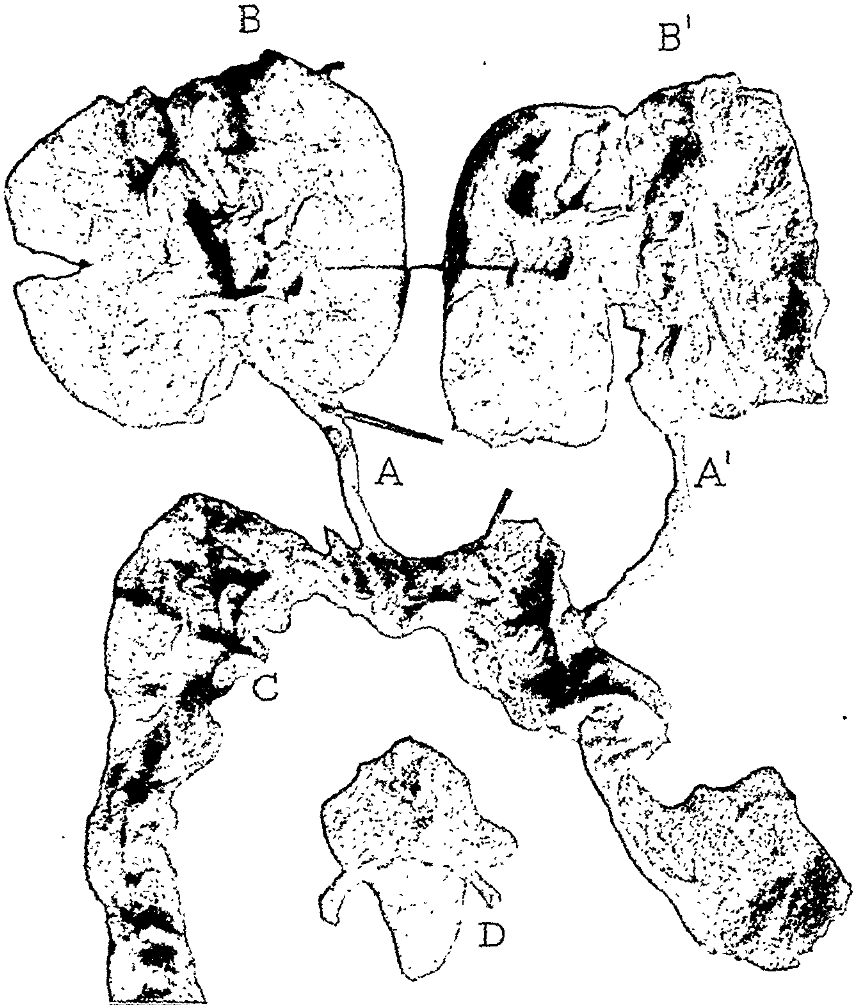

Fig. 3.—Implantation of ureter into intestine. *AA*, ureters; *BB*, kidneys; *C*, large bowel; *D*, bladder. About 3/16 actual size.

I waited many years for a chance to repeat this interesting operation for a similar indication. Last year the following case in my practice seemed to me to indicate at least a temporary transplantation of the ureters.

CASE 2.—*Patient.*—Mr. S., 60 years of age, was a packer in a crockery house. For the last sixteen years he had suffered from bladder-symptoms, which indicated either a stone in the bladder or an enlarged prostate. He had frequent urinations; occasionally his stream was interrupted suddenly and he had to strain; he also had to get up nights frequently; he suffered pain. The examination showed the prostate not much enlarged but a chronic hyperplastic cystitis; there was no stone in the bladder. But a roentgenogram revealed distinctly a stone of the size and shape of a nickel either encysted or in the left ureter.

First Operation and Results.—I decided to make a suprapubic cystotomy, and I found that the stone was contained in the left ureter about one inch above its orifice in the bladder. The ureter had to be split for that distance, and the stone was removed. It was noticed that a good deal of granulating tissue formed the bed of the stone. The patient did not make a very good recovery. It was interrupted by chills and fever and suppuration of the cavum retzii. He did not pass any urine in the natural way; the fistula had no tendency to close. During the following months several attempts were made to close the fistula and lead the urine the normal way but without success.

Second Operation and Results.—I decided, therefore, that the prostate, though it was not very much enlarged, must be the cause of this trouble and removed the prostate by an infrapubic cystotomy, draining the bladder downward and hoping for closure of the fistula of the abdomen. For a short while it seemed as if we would succeed, but only for a short while. Suppurations came again on the abdomen and the sinus caused the patient a great deal of trouble. Again I tried an excision of the sinus and closure of the bladder, but without success. In this time—about two years since the first operation—the bladder had become rigid and hard and could not retain regularly more than one ounce of urine, though at times, with much pain, the patient could distend it to hold several ounces.

Third Operation and Results.—I decided to make a last attempt; but when I had dissected down to the mucosa I found it so covered with ulcers and stony concretions that I thought the wiser plan would be to transplant the ureters, temporarily at least if not permanently, into the bowel and give the bladder a chance to heal out and to close, and, if it should do this and make a permanently closed viscus, to reimplant the ureters afterward. The man was in good health but unable to endure the flowing of urine over his abdomen or to wear a tube for drainage.

The operation was performed in a similar manner to that in the first case, except that the right ureter was implanted into the appendix. The man recovered promptly and has so far been able to control his urine for a couple of hours at a time. He is at least free from the molesting constant discharge of urine and the eczema. The fistula of the bladder is closing down at the time of writing this paper, and the bladder seems to be healing.

CONCLUSIONS

I considered this process of temporary transplantation analogous to temporary gastro-enterostomy for an ulcer of the stomach or duodenum.

Though only the short period of a few months has elapsed since the implantation in the second case, I am inclined to believe that this patient also will in course of time develop pyelitis; but his bladder may have a chance to recover and become a healthy viscus, and a reimplantation of the ureters may be made into the bladder, if he does not prefer the present tolerable condition.

In cases of tuberculosis of the bladder a permanent implantation made into the bowel is only palliative, but the method of free-end implantation of the ureter or the implantation into the appendix insures a longer period of freedom from pyelitis than any other. I think that it is even possible to implant both ureters into the appendix.

601 Deming Place.

Ureteric or Vesical Calculus.—Now it is a fact which has long since been accepted that a stone lodged in the ureter just near the bladder evokes all the symptoms of stone in the bladder, in addition to those symptoms which arise in the kidney from ureteric obstruction. There is the same frequency of micturition, the same tenesmus, the same meatal pain in juxtavesical ureteric stone as in vesical stone.—Hurry Fenwick, in (London) *Clinical Journal.*

THE REPAIR OF DEFECTS OF THE URETER *

DANIEL N. EISENDRATH, A.B., M.D.
CHICAGO

The surgeon is often confronted with a case in which a normal functionating kidney might be saved if a portion of the diseased ureter could be removed and the defect corrected either by some form of anastomosis of the severed ends or by substituting another structure for the removed segment of the ureter.

Anastomosis of the two ends has been seldom successful in the human being, when the ureter was divided either accidentally during operation or by injury or intentionally during the removal of a diseased segment. The various methods which can be employed for an anastomosis of the severed ends are (*a*) end-to-end, (*b*) end-to-side (Van Hook), and (*c*) invagination methods (D. Antona). Of these the ingenious method of Van Hook seems the most rational. It is superfluous to quote the technic here, since it is so well illustrated and described in all of the standard text-books of surgery. Owing to the tortuous course and elasticity of the human ureter, it is possible to unite the ends even though there is a gap of 3.2 inches (Von Bergmann). Experiments on dogs and results in human beings show that the Van Hook method of invaginating the proximal end into a slit on the lateral wall of the distal end gives the most satisfactory results of any method of anastomosis.

I have not considered, in this paper, the various methods of reimplantation of the proximal end of the cut ureter into the bladder or bowel. It is a well-recognized fact that one can resect the ureter close to the bladder or to the kidney and reimplant the corresponding end into another portion of the bladder or into the renal pelvis and thus save the kidney with perfect maintenance of its function. Reimplantation of the ureter into the bowel is impracticable on account of the irritant action of the urine on the mucous membrane causing persistent diarrhea and on account of the frequent occurrence of ascending infection.

The thought has occurred to many surgeons who have been obliged to resect a ureter either on account of its involvement in malignant disease or owing to a stenosis that, if some structure could be transplanted, the vitality of which would be maintained until union had occurred, the ureter could be resected and the corresponding healthy kidney saved. The structures which have thus far been employed with this object in view are (*a*) segment of an artery, (*b*) segment of a vein, (*c*) segment of the horn of the dog's uterus (fallopian tube), and (*d*) segment of the bowel or vermiform appendix. One fact favors the implantation of a segment of other structures, namely, that the ureter has within its own walls a rich vascular supply and that, although it is completely separated from surrounding structures, the vitality of the ureter is readily maintained. I shall briefly enumerate the names of those who have attempted to solve this problem and the structures employed as grafts between the two ends of the severed ureter.

1. Floercker, Melchior, Domenici and Tietze employed segments of arteries and veins.
2. Fenger and Bacon, Poggi and Tizzoni, D'Urso and DeFabi, Esou and Moskowicz employed loops of intestine, excluded

---

* From the Department of Experimental Surgery of the Morris Institute for Medical Research, Chicago.

from the remainder of the bowel, but still attached to their mesentery.

3. Gionnettasio, Rydygier and Frank transplanted the appendix, attached to its mesentery, but separated from the rest of the bowel.

4. Floercker, Stubenrauch, D'Urso and DeFabi used the long horn of the dog's uterus.

5. Casati, Boari and Van Hook used a flap of the bladder in the form of a tube, the upper end of which was sutured to the ureter.

The results in all of these cases may be divided into three groups: In the first, the flap became necrotic and general peritonitis resulted. In the second group of experiments, the proximal end of the ureter became adherent to the abdominal wall and a urinary fistula resulted. In the third group, the transplanted segment survived, but gradually became converted into connective tissue with resultant stenosis and hydronephrosis. The results in all of these experiments were uniformly unsuccessful. The reason for the difference in results obtained in transplanting a segment of blood-vessel into another blood-vessel and those obtained by transplanting the various structures just enumerated into the ureter can be explained according to Domenici and others by the following two hypotheses: (1) The blood circulating in the vessels will nourish the endothelium of the transplanted piece, while in the ureter the transplanted piece will become necrotic, lacking the circulating nourishing blood, before sufficient communications have been formed between the transplant and the ureter walls; or, (2) the necrosis of the transplanted piece of arterial or venous vessel can be caused by the difference in function of the ureter and blood-vessels, as the latter will not adapt itself to the new function. I thought that if we could secure as a free transplant a portion of the bladder, completely separated from the rest of the bladder, and insert this graft between the two ends of the divided ureter, we would thus secure a structure of which the lining membrane was accustomed to the presence of urine and thus less apt to undergo cicatricial changes.

The technic employed after a few preliminary trials was the same throughout the twelve experiments. The ureter was easily exposed through a pararectal incision. The entrances of the ureters into the bladder of the dog are easily found, the bladder itself being mobile and extending far up into the abdominal cavity like a pedunculated ovarian cyst. The fundus of the bladder was grasped by two fine artery forceps, and a portion of the fundus about 1 inch wide and 2 inches long severed from all connections with the remainder of the bladder. The bladder was then closed with two rows of fine chromic gut sutures.

In the insertion of this suture in the bladder the operator must exercise great care not to include the ureters in the suture. The trigone in the dog's bladder is long, the ureteral orifices lying some distance from the internal meatus and much nearer the vertex than in man. The ureter was divided transversely and a segment 1 inch long removed, and the severed ends temporarily clamped in order to prevent escape of urine and blood into the peritoneal cavity. It is usually necessary to ligate several of the periureteral vessels, especially at the distal end of the ureter. No attempt was made to bring the ends of the ureter into accurate approximation with the ends of the transplant owing to the great difference in the size of the lumen of the divided ureter and that of the tube formed by uniting the edges of the transplant. The method employed for bringing the ends of the ureter in contact is well shown in Figures 1 and 2. The ends of the ureter, both proximal and distal, were split and the ureter fastened to the interior of the wall of the transplanted bladder segment by several chromic gut sutures passing through the entire thickness of the wall of the transplant and tied on its outer aspect. A tube was then formed by suturing the edges of the transplanted bladder segment with one row of chromic gut through and through and a second seroserous row of fine arterial silk. In order to prevent the retraction of the ureter from the interior of the transplant, several chromic gut sutures were inserted through the walls of the ureter and transplant, above and below the entrance and emergence of the ureter (Fig. 2).

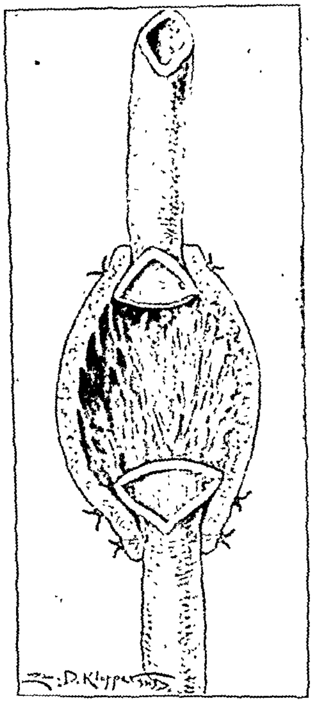

Fig. 1.—Method of inserting two severed ends of ureter in cuff of detached bladder flap.

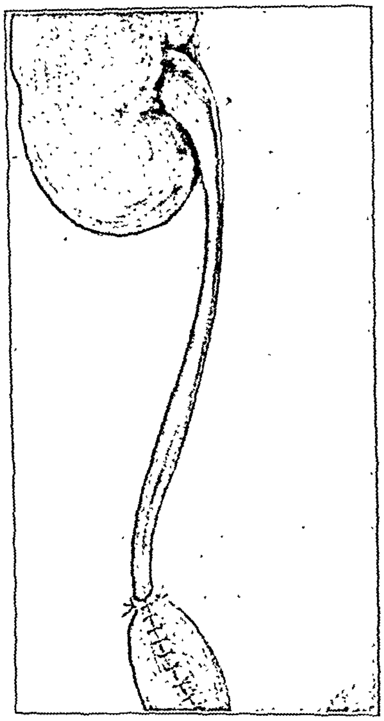

Fig. 2.—Exterior view of ureter shown in Figure 1.

The results obtained can be divided into the same three groups as those of the previous investigators. First, in several of the dogs the proximal portion of the ureter became adherent to the abdominal incision and a urinary fistula was established. Second, in six dogs the transplantation segment of bladder became necrotic before union had occurred between the ends of the ureter and the transplant, with subsequent leakage of urine and general peritonitis. The third group includes those cases in which the graft survived at least temporarily, but when the dogs were examined from four to six weeks after operation it was found that the transplanted bladder segment had contracted and had become converted into a mass of cicatricial tissue. The opening of the proximal end of the ureter was greatly narrowed so that the lumen at this point was reduced to a minimum. From this point upward the ureter was greatly dilated and there was a moderate degree of hydronephrosis.

The results, therefore, of my experiments, using free segments of bladder, are practically the same as those of other investigators who have employed segments of blood-vessels, bowel, appendix and uterine horn.

CONCLUSIONS

1. One can transplant portions of the bladder to take the place of segments of the dog's ureter.

2. These transplanted segments will preserve their vitality even though they have no vascular connection with the bladder.

3. It is immaterial whether the divided ends of the ureter are brought into exact end-to-end approximation with the transplant or are sutured to its inner surface in the manner described.

4. Even though the bladder mucous membrane is accustomed to the presence of urine, it will undergo cicatricial changes in the same manner as other structures, as artery, vein, appendix, bowel, horn of uterus, which are lined with endothelium or mucous membrane, not accustomed to presence of urine.

5. Even though union of the transplant occurs, it soon becomes transformed into connective tissue drawing the two ends of the ureters together with resultant stenosis of the ureter and hydronephrosis and hydroureter.

I wish to thank Dr. James W. Jobling for many courtesies.

31 North State Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. KROTOSZYNER, CAULK, EISENDRATH AND BECK

Dr. G. G. Smith, Boston: I should like to ask Dr. Caulk what anesthesia he used in removing these ureterovesical cysts in the bladder.

Dr. V. D. Lespinasse, Chicago: In some of my experimental work I have tried to replace the ureter with a segment of vein or artery. When I have done that in the bloodvessels, taken a segment out and put it back, there has been a change, and the tissues have become fibrous. The endothelium seems to remain intact, but the muscularis degenerates almost completely, and there is a stiff, rigid tube conducting the blood. When a vein or an artery was used as a ureter I had great trouble in securing a tight union. The work was done in the summer time, in August, and all my results in that line were failures.

In regard to Dr. Krotoszyner's paper: In hemorrhage from the kidney I have used a powder (thrombokinase) that is made from blood-serum and from extracts from certain organs, lungs and livers. I first hash up the organs and make a watery extract, and then precipitate with acetic acid. I have used that on a papilloma of the bladder which I curetted, and then impregnated gauze with this powder and packed the bladder. The result was ideal; the bladder was dry when the packing was removed. One of my friends used it in a case of hemorrhage from the kidney. He made an emulsion and injected this into the pelvis of the kidney. The hemorrhage from the kidney stopped. Whether it was due to the powder or not I do not know. Locally, on birthmarks and external bleeding surfaces, this ferment works nicely.

After you have tried these local measures and have succeeded in checking the hemorrhage or removing the kidney, the patients have sustained an enormous loss of blood, and transfusion is often necessary. Deaths in these cases are due absolutely to loss of blood, and it is surprising what can be accomplished by replacing the blood. The patients respond quickly. No patient should be allowed to die without attempting a direct transfusion of blood.

Dr. D. N. Eisendrath, Chicago: I do not quite agree with Dr. Caulk in the statement that the majority of these ureterovesical cysts are of acquired origin. That may be his personal experience, but the number of reported cases of congenital and acquired ureterovesical cysts is not yet large enough to state absolutely whether the congenital or acquired form is the more frequent. Up to the present time we have always been inclined to think that the congenital type was the more frequent, because we have just begun to discover these things through the cystoscope and recognize their nature.

I reported a number of cases of congenital stenosis which were recognized clinically, and a number which we had observed in the dissection of fetuses. One case of the typical congenital variety was of special interest; that of a little girl of 12, who had an enormous congenital dilatation of the lower end of the ureter. She presented the typical symptom of urinary retention to which Dr. Caulk referred. It was thought that she had a large ovarian cyst. On examination we found a dulness above the pubes in the median line, and every attempt to catheterize her would be resented, so that we were not able to make an examination and postponed the cystoscopic examination, not suspecting that this swelling was retention of urine. I made a median incision and found a distended bladder, the ureters being about the size of the thumb and both kidneys being hydronephrotic sacs. When we opened the bladder it looked as if there were a bladder within a bladder. The internal meatus was not obstructed, but evidently the ureterovesical pouch had pressed against it and caused retention. The left ureteral orifice was represented by a little pit, and above this a very much distended ureter was found by incising the mucous membrane of the bladder. I had never encountered anything of this kind and did not know at first what to do, but decided on the method which Dr. Caulk mentioned. We united the mucous membrane of the bladder with the mucous membrane of the ureter, and in that way obtained a good-sized opening. Everything progressed well for three months; but we were obliged to intervene a second time on account of persistent high temperatures. We examined the kidney of the same side and found it full of little abscesses, namely, an ascending pyelonephritis. We removed this kidney. The patient lived five months and died of uremia. The necropsy specimen showed a marked hydronephrosis on the opposite side and a hydroureter. This case had been one of ureterovesical cyst that had filled the entire lumen of the bladder.

Dr. Krotoszyner's paper is timely. He speaks about one hemorrhage occurring eight hours after operation. That is very early. The majority of these cases of secondary hemorrhage are due to the fact that thrombi which have formed become dislodged, the vessels open up again and hemorrhage results. In one case we dissected the specimen and found that there was free communication between an open vein and the area into which the drainage tube had been inserted. This is one of the chief reasons for postoperative hemorrhage, the pressure of drainage material on the open segments of vessels.

Another point brought out was the importance of primary nephrectomy for infected kidneys, provided the other kidney is able to do the work of both. The fibrous adhesions around the kidney, which we have tried to save when it was extensively destroyed by pus infection, are firm and dense. If the opposite kidney can do the work, or if the case is not a bilateral one, a primary rather than a secondary nephrectomy ought to be done.

Dr. O. S. Fowler, Denver: I should like to discuss Dr. Krotoszyner's paper from the point of view of insufficient diagnosis of stone, or orientation of the stone in the kidney. While I was an intern I observed seven cases of exploratory operations of the kidney, or rather operations on the kidney for the removal of stone, in which the stone shadow had been demonstrated clearly and there were evidences in the urine of stone in the kidney. In all of these cases the kidney was laid wide open from one end to the other. My observation of these cases disgusted me with the method of the general surgeon in handling kidney-stone. If you orient the stone accurately in the kidney, know exactly what calix it is in, or if it is in the pelvis, then you are able in most cases to remove the stone without a mutilating operation on the kidney. You can make a small opening directly over it, or directly into the pelvis, or extending from the pelvis into the kidney substance. Therefore, if the diagnosis is made with the aid of the Roentgen ray and collargol, we can locate the stone definitely. I do not believe that there is such a thing as a proper exploratory operation on the kidney. These procedures should be called mutilations. In the seven cases that I observed there were five cases of secondary hemorrhage sufficient to demand the removal of the kidney, and two of the seven patients died. There were over 70 per cent. of secondary nephrectomies following secondary hemorrhage. That sort of result was entirely unnecessary. I do not doubt that some hemorrhage will follow occasionally if the stone is entirely oriented and the smallest amount of destruction of the kidney done at the time of the operation, but I do not believe that, as has been said, a primary nephrectomy is advisable or necessary in these cases if a proper diagnosis is made.

Dr. Hugh Cabot, Boston: It is only within a few years that our attention has been directed to this condition. The difficulty lies in determining which of these cases are primary and which are secondary, which are congenital and which acquired. My own experience has been limited to six or seven cases, in all of which there was secondary disease of the kidney on one or both sides. We recognize that obstruction of some kind is at the bottom of the vast majority of our kidney lesions of an inflammatory nature, and this seems to me to explain the high percentage of kidney involvement in these cases of cystic change in the lower end of the ureter. I am inclined to regard them as due largely to a congenital fault of some kind, in many of which secondary changes in the kidney overshadow the changes in the ureter in such a way as to create the impression that they are acquired.

I was interested in Dr. Caulk's operation, because it is the only endovesical operation likely to give relief. I think that he has correctly estimated the slitting of the ureter as a temporary matter. The suprapubic operation is applicable to the more extensive cases. In one of my cases the cystic dilatation was nearly 3 inches in diameter, and I do not think that I could have managed that with an intravesical operation.

With Dr. Krotoszyner's paper I am largely in agreement. Dr. Fowler has laid stress on an important point; we should know where the stones are before undertaking their removal. In cases in which extensive damage has been done to the kidney, we should consider, and in most cases I believe should decide on, a primary nephrectomy. These pus-sacs full of stones are not of value to the patient. They are a constant source of worry and discomfort, and not an uncommon source of hemorrhage. I think that the danger to which the patient is exposed by keeping an old kidney warrants its removal. Our serious difficulty must come in cases of bilateral stones with extensively damaged kidneys on both sides. In a few of those cases nephrolithotomy will be necessary, but that is the only class of cases in which it is justifiable. The operation of pyelotomy is best in most cases. There are a few cases in which a stone is in the upper calix and can be reached through the cortex. I believe that when we do a nephrolithotomy through any considerable amount of kidney tissue we shall get hemorrhage, and the prevention lies in the careful study of the case and the adoption of better operative methods.

Dr. Louis E. Schmidt, Chicago: I agree with what Dr. Cabot and Dr. Eisendrath said with regard to the origin of these cysts, in spite of the fact that the cases reported by Dr. Caulk appeared to have been acquired. I am inclined to believe in an open operation, a thorough removal and the slitting up of the ureteral orifice. In one case in which I did this operation, the ureteral orifice remained wide open and gaping months afterwards without any apparent discomfort to the patient. Naturally, one must first consider whether infection is present or not, because the operative procedure might be entirely different. These intravesical operative procedures are naturally minor in character, but I do not believe that they can reach an obscure condition so thoroughly as the open operation does.

I am in perfect accord with what has been stated in Dr. Krotoszyner's paper. Hemorrhages undoubtedly follow as soon as eight hours after operation. It is possible that only a few have been recorded, but I know of quite a few in which hemorrhage has taken place within twenty-four hours after the operation. I am inclined to believe that in those cases it is due to an error in the operative technic. Hemorrhages that occur days later are undoubtedly due to secondary conditions that follow operative interference. I am also in accord with what Dr. Cabot says, that when the question of operative interference arises, in well-diagnosed conditions, if it is possible to do a pyelotomy, many of these hemorrhages will be avoided, but the great difficulty comes in cases in which we are dealing with double-sided lesions. Three weeks ago I was obliged to operate on a person for stone with a badly infected kidney, on whom I had done a nephrotomy five or six years previously. At the time of the operation there was severe hemorrhage, but on thorough suture the hemorrhage stopped completely. In a case of this kind in which drainage is absolutely necessary, the operative interference is a matter of considerable importance. It is out of the question that a man could do a nephrectomy in a case of this kind; so there are certain chances that you must take when you are operating on a person with one kidney, and the same thing applies when both kidneys are badly damaged.

Dr. William T. Belfield, Chicago: In a fairly large experience I have never seen serious hemorrhage follow nephrolithotomy. This good fortune may be due in part to the fact that I insert drains to, but never into, the kidney. For it is now established that pressure of a tube tends to erode blood-vessels.

Dr. John R. Caulk, St. Louis: I am thoroughly in accord with what Dr. Belfield has said, not in regard to cases of high-grade calculous pyonephrosis, but cases of renal stone in comparatively clean kidneys. I do not see the advantage of draining a kidney of that type. I have had quite a number of nephrolithotomies, and I have been fortunate enough not to have had a primary hemorrhage, and I believe that it is due to the fact that I have not put a tube in the pelvis of the kidney. I believe that even after bisecting the kidney, if we can get thorough approximation with mattress sutures we shall not often have hemorrhage. I cannot see the advantage of using a drainage-tube in a comparatively clean kidney.

Of course, pyelotomy is the method of choice with stones which are accessible and which can be removed easily through the pelvis, but with a branching calculus which is filling the calices, without much pelvic dilatation, I do not see that pyelotomy can offer a good chance, and I believe that if a clean nephrotomy is done and the kidney opened as little as possible (enough for exposure) and closed thoroughly, the chances of primary hemorrhage will be slight and the best results will be obtained. Of course, none of us can guard against secondary bleeding.

Dr. Hugh H. Young, Baltimore: Dr. Caulk, I think, has brought up an interesting field of surgery. His suggestion that my cystoscopic rongeur might be used has been carried out in one case of an intermittent balloon about the size of a cherry. We are able to grasp the whole thing and bite it off. The patient had previously had severe attacks of pain and was entirely relieved by that destruction of the cyst. I think that it amounts to practically the same thing as an excision.

It has occurred to me that, in transplantations of the ureter, the preservation of life of the part of the ureter that projects into the bladder or rectum will depend a great deal on whether we try, in doing the transplantation, to preserve the artery which passes along the ureter. Many years ago in transplanting the vas deferens and bringing it out into the groin for treatment we found that, if we stripped it closely, it always sloughed, whereas in cases in which we preserved the artery it would remain alive, even when it projected an inch. It occurs to me that, in one of his cases in which the end of the ureter sloughed and the other did not, he stripped one too closely. Certainly, in the bladder, it is generally entirely satisfactory to leave the ureter free, and it does not seem to make any difference whether we cut it obliquely, split it up, or cut it squarely off.

Dr. Krotoszyner's remarks on hemorrhage are extremely interesting. If we could have a few more papers in which an honest portrayal of our troubles and bad results could be given, it would do much good. A man, not in good condition, in whom a branching stone was removed from the cortex of the kidney, had recurrent hemorrhages for four or five weeks after the operation. The wound had been abundantly packed, but every time we removed the packing he had a hemorrhage. The last hemorrhage, four or five weeks after the operation, was so severe that it was out of the question, apparently, to carry out a nephrectomy, and we took advantage of the presence of his daughter and did a transfusion. That immediately stopped the hemorrhage. Although the patient had a violent chill and a temperature of 108 F., he recovered rapidly.

In a recent pyelotomy which I performed, the stone, which was small, had a hook-like process which passed up around one of the vessels, and a fearful hemorrhage occurred when we were removing the stone. It was impossible to reach the vessel by clamp, so I ran in a liver-needle and obtained about half an inch of kidney substance and the hemorrhage stopped.

Dr. John R. Caulk, St. Louis: In regard to anesthesia: In the first case the slitting operation was done under cocain. The second operation on the same person, that is, the resection, was done without any anesthetic, and the third was done without any anesthetic at all. As a matter of fact, I have seldom used cocain in the last few years. You can get along just as well without any anesthetic. If you use an anesthetic and are a bit rough, you traumatize the urethra, and, if the catheterization or operative procedure lasts any time, you are worse off, because edema follows, whereas if you use no anesthetic you are more gentle. I do not believe in using an anesthetic unless there is a very irritable urethra, as in tuberculous cases, although I have catheterized ureters through several tuberculous bladders without any anesthetic.

It is pretty hard to state in the case of an elderly person whom you see for the first time with an inflammatory process whether or not it is congenital. But I was led to believe that these cases were acquired, as there was a definite pathologic inflammatory condition in the lower ureter, which, of course, might be secondary. In two cases I know that it was an acquired anomaly, because in the first case, the one following the ureterovesical transplantation, I performed cystoscopy on the patient, in order to determine where the leak was, two months before I found the cyst. At that time there was no cyst, but following the transplantation the cyst developed; in other words, it was a definitely acquired condition. The other patient was one who was examined by a competent cystoscopist, who said that the bladder was suspicious of tuberculosis, but that she could find no tubercle bacilli. At this time there was no ballooning at all, but there was an ulcer around the right ureteral orifice. When I saw the case there was no ulcer, but a scar and the ballooning, which the doctor said she was confident were not there at the time of her examination.

I have done the slitting operation only once, and the condition immediately recurred. The endovesical operation for resection of the balloon is easy in women, if small instruments and a straight cystoscope are used. The results in these two cases have convinced me that they might be quite lasting—in one case one year and in one case two years. My experience in plastic operations on the ureter and bladder has not been particularly good, and I believe that, if one denudes a large area and allows it to granulate slowly, his chances of recontraction are not much greater than following an open operation, and, if he should have trouble later, he can do the major work, but let him give the patient a chance for the minor procedure first.

Dr. M. Krotoszyner, San Francisco: The wide discussion proves that the risks connected with nephrolithotomy are beginning to be recognized. Faulty surgical technic, I am sure, is not responsible for hemorrhage after nephrotomy, for accidents similar to my own are reported by the best technicians from all over the world. I fully coincide with Dr. Fowler in his demand for a careful preoperative study of every case of nephrolithiasis. A nephrectomy is, of course, only permissible on the basis of a painstaking cystoscopic and functional investigation, but wherever, under such conditions, a pyonephrotic stone-kidney was removed by me, the immediate and remote results of the operation were exceedingly gratifying.

STUDIES OF THE NECROSIS FOLLOWING INJECTIONS OF SALVARSAN AND NEOSALVARSAN *

H. E. ROBERTSON, M.D.
Associate Professor of Pathology, School of Medicine, University of Minnesota
MINNEAPOLIS

When salvarsan was introduced as a specific cure for syphilis its administration by deep intramuscular injections was strongly recommended. Wolbarst,[1] in 1912, stated that Ehrlich believed that "salvarsan is essentially an intramuscular injection," and if pain could be avoided this method would be the one of choice. Meltzer[2] showed that the intramuscular injections were absorbed more rapidly than the subcutaneous, but recommended the sacrospinal muscle rather than the gluteal as being less apt to cause pain and other complications. It was soon apparent, however, that the intramuscular injection of salvarsan almost uniformly produced intense pain; the wound healed slowly, and often was followed by large sloughing areas of necrosis which were extremely resistant to all attempts at aiding or producing complete repair. K. Martius[3] concluded that this method produced necrosis in every case in which it was used. Buschke[4] also stated the same fact and called attention to the numerous examples of slow healing necroses occurring in the gluteal muscles following their injection by salvarsan. Wise[5] proved that these lesions may follow the use of acid, alkaline or neutral solutions of the drug and to a lesser extent the use of paraffin or oil suspensions.

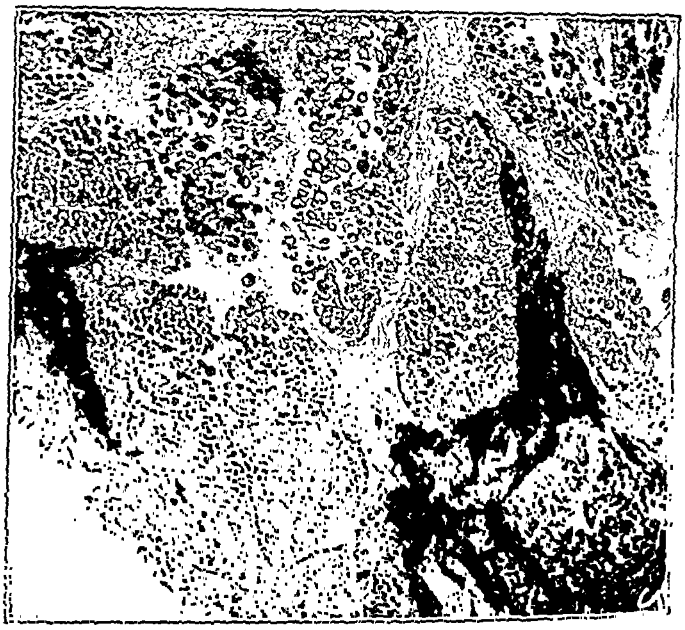

Fig. 1.—Salvarsan; eleven hours; necrosis; leukocytic infiltration. Dark mass represents salvarsan pigment. × 41.

[5] Wise, New York Med. Jour., 1911, xciii, 820.

The opinions quoted show in fact the almost universal experience of those who have used the drug by this method, and these facts have caused most clinicians to advise that the intramuscular route be abandoned in favor of the intravenous.

Lovejoy[6] and Sutton[7] each described the histologic appearances of tissue removed from the site of an intramuscular injection a few months later. They both found granules of salvarsan in the tissue and the smaller vessels and lymph-vessels blocked by these granules. To this fact they attribute the failure to heal. They each emphasized the absence of lymphoid cell infiltration.

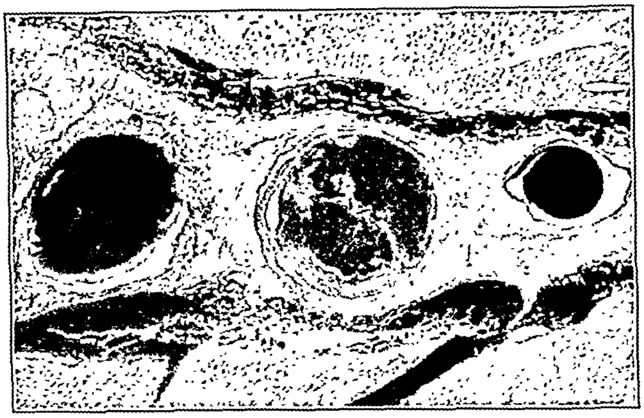

Fig. 4.—Salvarsan; three days; thrombosis of vessels; salvarsan pigment at margins. × 41.

My work leads me to question the accuracy of these observations on the location of the salvarsan particles, which have never been found blocking the vessels, and I have also noted that lymphoid-cell infiltration is uniformly present in the later stages of the lesion.

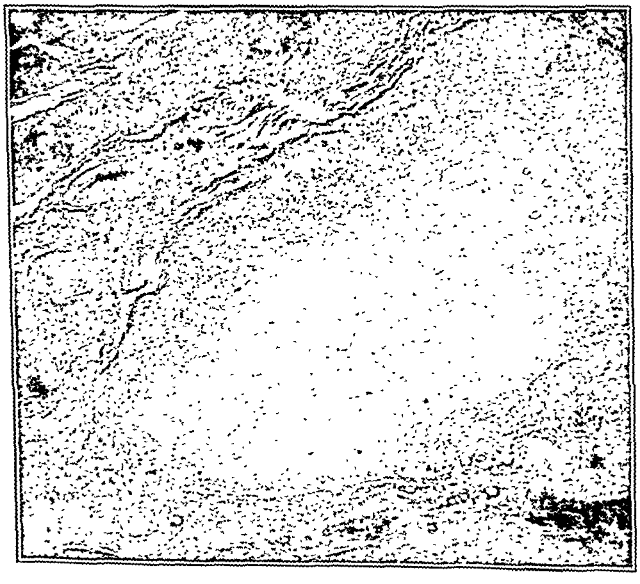

Fig. 5.—Salvarsan; fifty-one days; localized area of necrosis with zone of leukocytes. × 41.

Tomaszewski[8] experimented on pigeons by injecting alkaline solutions, neutral emulsions and oil suspensions of salvarsan into the muscles. In all cases diffuse areas of necrosis appeared on the first day. Later these became walled off by a zone of leukocytes and then by newly forming connective tissue. Only a scar remained at the end of seventy days.

These results were fully confirmed by my experiments.

Slusher and Burchell[9] demonstrated that salvarsan has very weak if any antiseptic properties and that therefore strict aseptic precautions are necessary in its administration.

In spite of these well-recognized sequelae, however, the necessity of acquiring some degree of experience and technical skill has often proved a bar to the application of the intravenous method in the hands of many physicians, and, consequently, when the preparation called neosalvarsan was announced, its ready solubility in water and ease of preparation gave some ground for the belief that the easier method of intramuscular administration would again become the method of election in the majority of cases. This hope has not been fulfilled, although fewer reports of muscle necrosis are appearing in the recent literature, probably owing to the fact of the widespread adoption of the intravenous method.

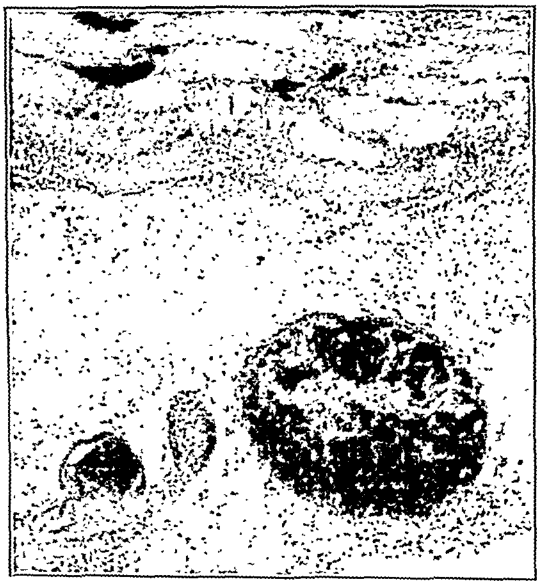

Fig. 6.—Neosalvarsan; eleven hours; thrombophlebitis with degeneration of muscles. × 210.

Swift[10] while investigating the comparative absorption of arsenic following intramuscular injections of salvarsan and neosalvarsan found that both uniformly produced necrosis in the muscles of rabbits, but that salvarsan always caused the more intense reaction.

My own work was carried on for the purpose of making intensive studies of this peculiar type of necrosis and of observing (1) the effects of salvarsan on the muscles of animals compared with its effects on the muscles of human beings, (2) the effects of salvarsan compared with those of neosalvarsan, and (3) the effects of both of these drugs compared with those produced by deep injections of the more commonly employed mercurial preparations still used in the treatment of syphilis.

In the preparation of the salvarsan and neosalvarsan solutions for injection the directions given in the circulars accompanying the drug were closely followed and the size of the dose was governed by the body-weight of the animals compared with that of an average man. At various times the amount of the drug was purposely slightly increased or diminished without, as far as could be observed, altering appreciably the extent or character of the lesion produced. Dogs were used for all the animal experiments and injections were made into the extensor muscles of the thigh in the hindquarter and the corresponding muscles of the shoulder in the forequarter. All injections were made only after partial narcosis by subcutaneous administration of morphin sulphate had been produced. Aseptic precautions were observed throughout.

---

[10] Swift: Jour. Exper. Med., 1912, xvii, 83.

The results of experiments with salvarsan and neosalvarsan are summarized in Table 1. This series developed several interesting facts:

1. The lesion in these cases consists of hemorrhage and necrosis with edema which develops almost immediately after the injection. Leukocytes early invade the tissue and tend to form a zone around the necrotic area.
2. Salvarsan invariably leaves a deposit of insoluble yellow pigment which acts in every respect as a comparatively inert foreign body.
3. There is no appreciable difference between the severity of the lesions which appear after the intramuscular injections of either salvarsan or neosalvarsan. If anything, neosalvarsan tends to give a slightly more diffuse zone of destructive inflammation.

Reparative processes begin in about a week, but the absorption of the necrotic material proceeds very slowly, and usually is not completed until a period of at least two months has elapsed. Infiltration of phagocytic endothelial cells and lymphocytes occurs in the later stages. Thrombosis of the venous branches is a very common finding and undoubtedly accounts for the tendency to sloughing and slow healing so often observed in human cases. Accidents, such as large hemorrhages and abscess formation, are possible. Although no data were secured as to bacterial infection, I do not believe that this is a common complication. When the injection accidentally was made into the intermuscular fascias, necrosis and other inflammatory phenomena were much less prominent, and recovery was correspondingly more prompt.

TABLE 1.—SALVARSAN AND NEOSALVARSAN IN MUSCLE

o.	Animal	Preparation	Site of Injection	Duration After Injection	Gross Appearances	Microscopic
1	AE-13-73	Salvarsan	L. shoulder	2⅓ hr.	Local hemorrhage; edema; yellow pigment from drug.	Hemorrhage; emigration of leukocytes; edema; muscle-fibers swollen and vacuolar with irregular staining and loss of striations; salvarsan pigment.
2	AE-13-73	Neosalvarsan	R. shoulder	2⅓ hr.	Ditto, except pigment is absent	Leukocytes more numerous; degeneration of muscles more pronounced.
3	AE-13-73	Salvarsan	L. thigh	11 hrs.	Wide-spread edema; area of hemorrhage and necrosis with yellow pigment.	Hemorrhage, necrosis and degeneration more advanced; much salvarsan pigment.
4	AE-13-73	Neosalvarsan	R. thigh	11 hrs.	Ditto, except pigment is absent.	Di [illegible] ent and veins [illegible] formation.
5	AE-13-115	Salvarsan	R. shoulder	1 day	Similar to No. 3.	Le [illegible], otherwise re- [illegible]
6	AE-13-115	Neosalvarsan	L. shoulder	1 day	Necrosis and hemorrhage more marked than in No. 5.	Hemorrhage and necrosis very prominent; only slight leukocytic infiltration.
7	AE-12-7	Salvarsan	R. shoulder	2 days	Similar to No. 3.	Similar to No. 3.
8	AE-12-7	Neosalvarsan	L. shoulder	2 days	Similar to No. 6.	Extensive leukocytic infiltration; otherwise similar to No. 6.
9	AE-12-171	Salvarsan	L. thigh	65 hours	Edema less pronounced; hemorrhage and necrosis more localized; pigment present.	Beginning formation of zone of leukocytes; otherwise like No. 3.
10	AE-78-171	Neosalvarsan	R. thigh	65 hours	Similar to No. 9, except pigment is absent.	Similar to No. 9 except pigment is absent.
13	AE-13-115	Salvarsan	R. thigh	3 days	Similar to No. 9.	Similar to No. 9.
14	AE-13-115	Neosalvarsan	L. thigh	3 days	Development of abscess.	Extensive necrosis and leukocytic infiltration.
15	AE-12-7	Salvarsan	R. thigh	6 days	Similar to No. 9.	Localization of exudate; pigment present; beginning proliferation of connective tissue.
16	AE-12-7	Neosalvarsan	L. thigh	6 days	Similar to No. 10.	Old hemorrhage; proliferation of connective-tissue cells; localization of exudate about necrosis; no pigment.
17	AE-12-170	Salvarsan	L. shoulder	7 days	Extensive necrosis; abscess pockets.	Large areas of necrosis; masses of leukocytes; no bacteria found.
18	AE-12-170	Neosalvarsan	R. shoulder	7 days	Similar to No. 16.	Similar to No. 16.
19	AE-12-157	Salvarsan	R. shoulder	15 days	Large old hemorrhage; necrosis and pigment.	Localization of exudate; new connective tissue with fibroblasts and capillaries; many large mononuclear cells containing both salvarsan and old blood pigment; old necrotic muscle fibers surrounded by giant cells.
20	AE-12-157	Neosalvarsan	L. shoulder	15 days	Necrosis of fascia and adjoining muscle; induration.	Fresh fibrosis with thrombosis of several large veins; masses of leukocytes.
21	AE-12-170	Salvarsan	L. thigh	18 days	Localized area of necrosis with pigment and indurated margins	Similar to No. 19.
22	AE-12-170	Neosalvarsan	R. thigh	18 days	Like No. 2 without pigment.	Zone of necrosis surrounded by zone of fresh fibrosis and at margins apparent proliferation of muscle nuclei.
23	AE-12-152	Salvarsan	R. shoulder	23 days	Similar to No. 21.	Similar to No. 19.
24	AE-12-152	Neosalvarsan	L. shoulder	23 days	Similar to No. 22.	Similar to No. 22 with addition of numerous lymphocytes.
25	AE-12-151	Salvarsan	R. thigh	24 days	Similar to No. 21.	Giant-cell formation around masses of pigment; phagocytic large mononuclear cells; advancing fibrosis.
26	AE-12-151	Neosalvarsan	L. thigh	24 days	Induration of fascia.	Fresh fibrosis in fascia; no changes in muscle.
27	AE-12-152	Salvarsan	R. shoulder	32 days	Pigment in fascia.	Fresh fibrosis; chronic changes in blood-vessel walls; lymphocytic infiltration; salvarsan pigment.
28	AE-12-152	Neosalvarsan	L. shoulder	32 days	Local area of necrosis with indurated margins.	Area of necrosis with zone of exudate and organization; arteriosclerosis; thrombosis of some vessels.
29	AE-12-172	Salvarsan	L. thigh	51 days	Old small area of necrosis.	Dense fibrosis; infiltration of lymphocytes; pigment masses in cells and tissue spaces.
30	AE-12-172	Neosalvarsan	R. thigh	51 days	Injection in fascia; few if any traces.	A few degenerated muscle fibers; otherwise no lesion.

4. Variations of the amount of the drug injected from one-half to twice the amount advised do not appreciably affect the extent of the lesion.

5. No changes in the general health of the animal could be observed, and there was no evidence of any marked tenderness at the site of the injections and no apparent limitation of motion unless abscesses developed.

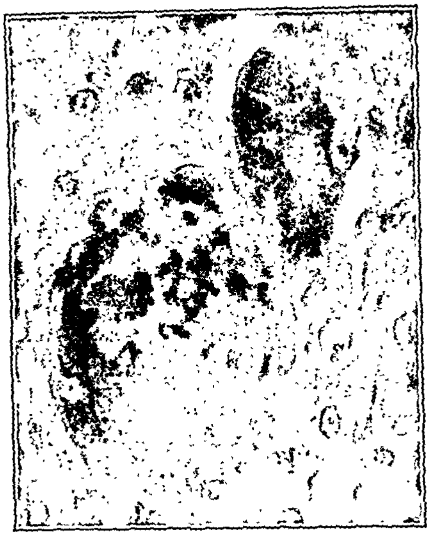

Fig. 8.—Neosalvarsan; thirty-two days; giant cells around muscle fibers. × 1300.

For purposes of comparison a second series (Table 2) was undertaken, using the mercurial preparations which are commonly employed for intramuscular injection in cases of syphilis. As may be seen in the table, the reaction is very similar, at least in its early stages, to that obtained with salvarsan and neosalvarsan. The results are, however, probably not quite so severe. Controls with distilled water and sodium bicarbonate show that this is an inflammation produced chemically rather than mechanically.

The results of injection of salvarsan into the muscles of human beings were further confirmed by the following two cases which came to necropsy:

Case 1.—Mrs. W., aged 38, suffering from a supposed syphilitic destructive necrosis of the nasopharyngeal passages, received injections of salvarsan into the gluteal muscles of both sides eleven days before death. At the post-mortem examination these muscles showed areas of necrosis and hemorrhage, brown, and firm in consistence. Cross-sections of the affected muscle suggested the appearance of a large adrenal gland with brownish-yellow peripheries and grayish-white centers. The condition in the nose proved to be a destructive diffuse carcinoma with gangrene.

Microscopically, the lesion closely simulated that seen in the muscles of dogs at the end of one week. Extensive necrosis with degeneration of muscle bundles, edema and leukocytic infiltration were prominent features. Masses of brownish salvarsan pigment were abundant. Beginning proliferation of connective-tissue cells could be seen at the margins of the lesion. Several of the veins showed thrombosis.

Case 2.—Mr. B., aged 40, suffered from a typical clinical attack of syphilitic myelitis. His blood gave a positive Wassermann reaction. Salvarsan was injected into the muscles of the chest wall four months before death. At necropsy, small, firm, scar-like masses of tissue were found at site of injections. These showed deposits of yellowish pigment. The typical lesions of a diffuse myelitis were clearly demonstrated.

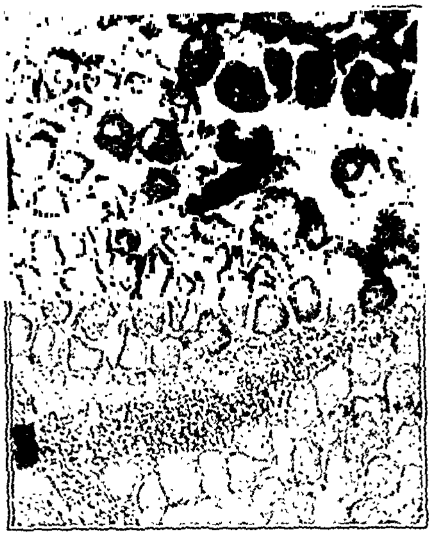

Fig. 9.—Mercuric salicylate; three days; disorganization of muscle fibers; leukocytic infiltration. × 410.

Microscopically, there was extensive overgrowth of young connective tissue. Muscle fibers appeared in varying stages of degeneration. The tissue was diffusely infiltrated by lymphocytes and plasma-cells.

TABLE 2.—MERCURY PREPARATIONS IN MUSCLE WITH CONTROLS

No.	Animal	Preparation	Site of Injection	Duration After Injection	Gross Appearances	Microscopic
32	AE-13-6	Mercuric chlorid	R. shoulder	3 days	Areas of hemorrhage and necrosis; edema.	Hemorrhage; diffuse necrosis; degeneration of muscle fibers; infiltration of leukocytes.
33	AE-13-6	Mercuric cyanid	R. thigh	3 days	Hemorrhage in fascia.	No sections.
34	AE-13-6	Mercuric succinimid	L. shoulder	3 days	Similar to No. 32.	Similar to No. 32.
35	AE-13-6	Mercuric salicylate	L. thigh	3 days	Extensive hemorrhage, necrosis and edema.	Similar to No. 32.
36	AE-12-6	Mercuric chlorid	R. shoulder	5 days	Edema and necrosis.	Beginning localization of exudate around areas of necrotic muscle.
37	AE-12-6	Mercuric cyanid	R. thigh	5 days	Hemorrhage, edema and necrosis.	Hemorrhage; necrosis of muscle; no evidence of leukocytic invasion.
38	AE-12-6	Mercuric succinimid	L. thigh	5 days	Hemorrhage and necrosis.	Necrosis; a few leukocytes surrounding degenerated muscle fibers; basic staining masses of pigment.
39	AE-12-6	Mercuric salicylate	L. shoulder	5 days	Edema and necrosis.	Extensive necrosis; leukocytic infiltration; masses of basic staining pigment; beginning thrombosis of veins.
11	AE-12-171	5 per cent. sodium bicarbonate	L. shoulder	65 hours	No gross lesion.	No lesion.
12	AE-12-171	Distilled water	R. shoulder	65 hours	No gross lesion.	No lesion.

SUMMARY

1. Intramuscular injections of salvarsan and neosalvarsan uniformly produce severe destructive lesions which always heal slowly and often are complicated by hemorrhages and sloughing abscesses.

2. The severity of the reaction from the use of either drug is essentially the same.

3. Salvarsan always leaves an insoluble pigment which acts as a foreign body.

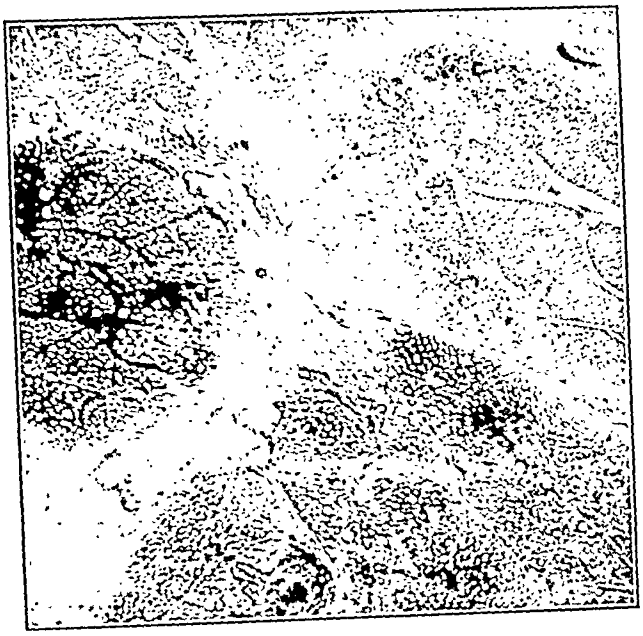

Fig. 10.—Mercuric cyanid; five days. Hemorrhage and necrosis. × 41.

4. Mercurial preparations when injected into muscles produce similar lesions.

5. The lesions produced by experiments on animals and in human beings are similar in every respect.

6. The use of such preparations in this manner in certainly the majority of cases is an unjustifiable procedure.

DECIDUAL REACTION IN THE APPENDIX IN INTRA-UTERINE PREGNANCY

GEORGE W. OUTERBRIDGE, M.D.
Assistant Instructor of Surgical Pathology in the University of Pennsylvania, Department of Medicine; Outpatient Surgeon and Pathologist to the Gynecean Hospital
PHILADELPHIA

One of the most interesting phenomena observed in connection with both normal and ectopic gestation is the occurrence at various locations outside the uterus of tissue having a histologic appearance nearly or quite identical with that of decidua. It has been conclusively shown that the normal, intra-uterine decidua represents nothing more nor less than a transformation of the endometrial stroma, as a result of which the majority of the connective-tissue cells have become much swollen, and have assumed a round, oval or more or less polygonal shape. The cytoplasm often contains vacuoles, probably of glycogen; the nuclei also are somewhat swollen and vesicular, and often occur two or three to a single cell. The cells lie close together, but are separated by fine fibrous trabeculae; scattered among them are usually seen a few small, deeply staining, unchanged connective-tissue cells, the whole structure presenting a very characteristic and, for the most part, easily recognized appearance. The occurrence during pregnancy, at various points of the pelvic peritoneum, of small clumps and larger masses of cells possessing precisely similar characteristics has been observed and described by numerous authors. Located always just beneath the surface epithelium or endothelium, these extra-uterine decidual masses are found most frequently on the posterior surface of the uterus, at the bottom of the pouch of Douglas and on the anterior surface of the rectum; and somewhat less often on the anterior surface of the uterus, the posterior wall of the bladder, the surface of the tubes and small intestines and in the outer layers of the ovarian stroma; they have also been reported a few times in the omentum, and at least once each in a parovarian cyst, the vagina and the appendix.

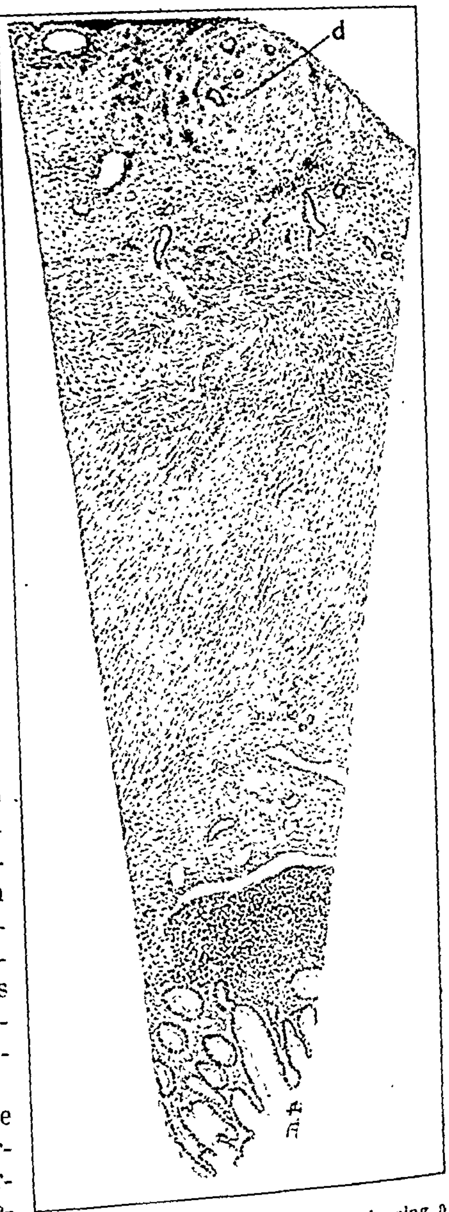

Fig. 1.—Low-power drawing showing a group of decidua-like cells (*d*) in the thickened and much-inflamed serous coat of the appendix.

First described by Walker[1] in connection with abdominal pregnancy, later by Dobbert[2] in a case of tubal pregnancy, the occurrence of this extra-uterine decidua coincident to normal, intra-uterine gestation was first demonstrated in 1895 by Pels-Luesden,[3] whose finding has since been confirmed by Schmorl,[4] Lange[5] and numerous other investigators. There can be no question of these little nodules representing anything in the nature of metastases from the endometrial decidua; they arise by a transformation *in situ* of the subserous connective-tissue cells, analogous to that occurring in the uterine mucosa, and it is almost always possible to demonstrate numerous intermediate stages between the small, unchanged, fixed connective-tissue cells and the large, fully developed, decidua-like ones.

So far as I have been able to ascertain, the occurrence of this reaction in the appendix has been observed in but one instance, reported by Hirschberg[6] in 1905. His patient was a 38-year old multipara who was operated on for ectopic gestation, the right pregnant tube, with adherent appendix, being removed. Examination of the latter organ showed a marked periappendicitis, due, the author believed, to irritation from the blood discharged into the pelvis from the pregnant tube; in the deeper portions of the thickened serosa of the appendix were numerous large groups of typical decidual cells whose origin was evidently to be referred to the connective-tissue cells of that locality. Although in this instance the appendix was closely adherent to the gestation sac, Hirschberg ventured the opinion that the presence of such adhesions is not to be considered a sine qua non for the occurrence in the former of decidual reaction, but that this might, under some circumstances, take place also in connection with a left tubal pregnancy. That he was right, at least in the first part of this assumption, and that, moreover, decidual reaction can occur in the non-adherent appendix in connection with normal, intra-uterine pregnancy, is shown by the following case:

[5] Lange: Beitrag zur Frage der Deciduabildung in der Tube bei tubarer und intrauteriner Schwangerschaft, Monatschr. f. Geburtsh. u. Gynäk., 1902, xv, 48.

History.—Mrs. S., aged 37, was delivered of a full-term, living child under the care of her family physician, who had not seen her for several days before being called to attend her in active labor. He noticed that she seemed to complain somewhat excessively of pain and that her abdomen was rather tender, but otherwise the delivery was entirely normal. On revisiting the patient ten hours later, however, the doctor found her in very bad condition; the abdomen was enormously distended, and she was vomiting large quantities of stercoraceous material. As it was evident that some serious intra-abdominal condition was present, demanding immediate interference, she was removed to the Gynecean Hospital, where she was operated on by Dr. Theodore A. Erck about fourteen hours after delivery.

Operation and Result.—When the abdominal cavity was opened, a considerable quantity of free pus was found; the surface of the intestines was congested, dull, and in places covered with lymph, but there were practically no adhesions, the process being apparently too acute. The appendix was quickly located; it appeared acutely inflamed, but there were no evidences of adhesions. It was removed, and the wound closed with free drainage, but the patient was in a desperate condition throughout, and died early the next morning. No necropsy was performed.

Laboratory Report.—Grossly, the appendix[7] appears markedly inflamed and considerably thickened, measuring 6 cm. in length by 1 cm. in diameter; it is covered with lymph in places, but does not show any point of perforation. Microscopically, the wall is seen to be thickened throughout, and to be the seat of an acute inflammatory process, diffuse in type, but much more marked in the serous and mucous than in the muscular coats. The glands of the mucosa are dilated with mucus, and there is considerable infiltration, chiefly with eosinophils, throughout this coat. A round-cell infiltration of moderate degree is present in the submucous and muscular coats, but in the greatly thickened serosa the cellular infiltration becomes most intense, consisting here in large part of polymorphonuclear neutrophils, in addition to small round cells and eosinophils. There are numerous markedly congested capillaries just beneath the surface.

Scattered throughout this greatly thickened subperitoneal tissue are numerous groups of large, polygonal cells, which at once attract attention from their dissimilarity to anything ordinarily seen in the appendix. In some areas these large, very prominent cells show a more or less diffuse arrangement, making up practically the entire tissue, but for the most part they are collected into fairly definite groups, the majority of which are situated beneath the surface, one or two, however, projecting slightly above it. In the center of a few of the cell-groups are a number of good-sized, engorged capillaries, but in the majority these are wanting, the cell masses being for the most part compact, and showing no relation to blood-vessels. By suitable staining methods, a delicate fibrous network can be made out between most of the cells, and the entire arrangement is practically identical with that of ordinary decidua, although the development is nowhere so extensive as that regularly found in the endometrium (Figs. 1 and 2).

The situation of these cells stamps them as having arisen from the connective-tissue cells of the greatly thickened stroma of the serosa; nowhere is there any tendency for them to spread out in a sheet immediately beneath the surface, as would surely be the case had they arisen from the surface endothelium. A sharp differentiation between the decidua-like cells on the one hand and endothelial cells of the peritoneum on the other, which Hirschberg was able to demonstrate in his case, is impossible in the present instance, however, as the endothelium has been practically destroyed, and replaced by inflammatory tissue and lymph. The assumption that the large cells owe their origin to the inflammatory condition alone, irrespective of any influence from the pregnancy, does not seem justified, in view of their dissimilarity to anything ordinarily seen in connection with the various forms of appendiceal inflammation, but it is undoubtedly true that the presence of the active inflammatory process may have been a contributing factor, as will be pointed out later on. It certainly seems more probable that the presence of these cells in the appendix represents a true decidual reaction on the part of its stroma.

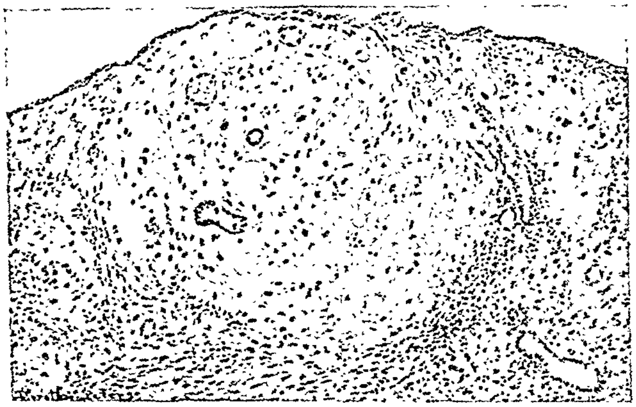

Fig. 2.—Higher-power drawing of the same group of cells.

In order to determine whether the apparent infrequency of decidua formation in the appendix might not possibly be due to its occurrence having been overlooked, I have gone through the collections of the laboratory of gynecologic pathology of the University of Pennsylvania and of the pathologic laboratory of the Gynecean Hospital, examining all appendixes which have been removed during the past few years in conjunction with ectopic or normal pregnancy. Owing to the fact that cases in which the appendix is removed under these circumstances are not very common, the series comprises but twenty-three specimens, one of which occurred in connection with an intra-uterine pregnancy, all the others with some form of tubal gestation. With but one or two exceptions, at least two sections of each appendix, taken from different portions of the organ, were carefully examined. Included in the series were appendixes which had been densely adherent to the tubal mass, and others in which no such adhesions had been present; there were normal appendixes, and specimens showing all the common types of inflammation, ranging from slight catarrhal or interstitial changes to partial or complete obliteration or acute diffuse processes. In a few instances a marked periappendicitis was present, fully as intense as that in the case described, but in no single instance was anything seen even remotely suggestive of decidua formation. In one case, scattered about the outer edge of the longitudinal muscular coat, were a few small groups of two or three large cells each, but these did not resemble in the least the structure of decidual tissue, and would probably have passed unnoticed, had not the attention of the examiner been directed especially to the discovery of any enlarged or swollen cells; they appeared to represent merely an inflammatory reaction of the endothelial cells of small lymph-vessels, such as is not infrequently seen under various conditions.

[6] Hirschberg: Deciduale Zellbildung am Wurmfortsatz bei Tubenschwangerschaft (Periappendicitis decidualis), Arch. f. Gynäk., 1905, lxxiv, 620.

[7] Specimen was demonstrated before the Pathological Society of Philadelphia, Feb. 27, 1913.

While this series is, of course, too small to permit of any wide generalization, it coincides as far as it goes with the experience of other investigators. Hirschberg examined the appendix from a second case of tubal pregnancy, and was unable to find decidua, and Taussig[8] examined a specimen from a ruptured tubal pregnancy of the right side, in which the appendix was embedded in hemorrhagic masses and was removed with the gestation sac. In this instance "a large number of sections were made from three portions of the appendix and mesentery, but no trace of decidua was found anywhere."

Of great interest in connection with cases of this character is the question of the etiology of the extra-uterine decidual masses—a question which can hardly be separated from that of the etiology of decidua in general. From a somewhat similar study of the subject, Taussig has come to the conclusion that certain end-products of placental metabolism incite in the loose connective-tissue cells of the uterine mucosa the typical decidual change, and that the end-products exert a similar influence on the subperitoneal connective-tissue cells of the various other parts in which this has been found. Since the extra-uterine decidual reaction occurs always near the surface of whatever tissue it involves, Taussig believes that some surface irritation must play an important rôle, but that since the decidua-like cells occur in scattered, more or less circumscribed patches, the causative influence, whatever its nature, cannot be transmitted by a soluble substance, or by way of the blood-vessels or lymph-channels. He has therefore advanced the theory that cellular detritus from the placenta passing out through the lumen of the tubes, and becoming scattered over the pelvic peritoneum, might bring about a spread of the irritation which would fulfil the requisite conditions.

While this theory appears at first sight fairly plausible, it does not appeal to me as a very satisfactory explanation for the majority of cases, and certainly not for the one at present under consideration, in which there were no adhesions to bring the appendix—the site of the decidual reaction—into especially close relationship with the uterus, tubes or any other portion of the genital system. Moreover, a rather cogent argument against the origin of uterine decidua being dependent on the end-products of placental metabolism would seem to be furnished by the fact that not only does the decidual change begin to take place in the endometrium before there is any suggestion of placenta formation, but that at each menstrual period the stroma cells of the endometrium undergo changes which are identical with the first steps of decidua formation, and result in the production of a histologic picture that can with great difficulty be distinguished from early decidua. Indeed, the difference between the true decidual tissue of pregnancy and the pseudodecidua of menstruation is one of degree, rather than of quality, the former undergoing a routine development far richer and more perfect than is ever attained by the latter.

As I have pointed out in a previous paper[9] on decidual reaction in the omentum, the theory advanced by Loeb[10] to account for the formation of intra-uterine decidua appears, perhaps, to offer a more satisfactory explanation for its occurrence likewise outside the uterus. Loeb's theory, based on careful animal experimentation, is, in brief, that the corpus luteum elaborates a sensitizing hormone, under the influence of which the stroma-cells of the endometrium react to any non-specific irritation —such as the introduction of a small foreign body into the uterus—by the formation of a decidua, the necessary irritation being furnished under normal conditions by the lodgment of the fertilized ovum. If the presence of such a hormone can thus sensitize the stroma-cells of the uterine mucosa, why may it not be assumed to exert a similar influence on the connective-tissue cells of other areas, so that when acted on by any sufficient irritant, they too will undergo a similar transformation—less well-developed, however, inasmuch as this tissue is not so well adapted to undergo the characteristic changes as is the loose endometrial stroma? The fact that in addition to the presence of the sensitizing hormone, this second factor of local irritation appears to be necessary to cause any considerable decidua formation, would seem to furnish a sufficient explanation for the occurrence of this in scattered patches rather than diffusely; only at those points at which some slight mechanical or other stimulus is active do the cells undergo a decidual change. The occurrence of the reaction usually just beneath the surface may be explained on the ground that the tissue in this location is rather loose, so that its cells have a better opportunity to expand than do those of the deeper structures, as well as by the fact that the local irritation is probably, in most instances, exerted from the surface.

In the case of the appendix described in this paper, the intense inflammation present undoubtedly furnished the irritative stimulus necessary to produce the reaction; that a similar reaction is not found in all inflamed appendixes removed during ectopic or normal pregnancy is probably to be explained in the same way as its failure to occur, in some instances, in the tubal mucosa, or in any other of the numerous extra-uterine situations in which, in other instances, it does develop. Ectopic decidua appears, on the whole, to be extremely fitful in occurrence, a circumstance which—if we accept the previously outlined theory—may be ascribed to variations in the intensity of action of the ovarian hormone, to different degrees of responsiveness on the part of the subperitoneal connective-tissue cells, or to the presence or absence of suitable local stimuli, each of these factors undoubtedly varying greatly in individual cases. Viewed from this point of view, the appendix must be considered an organ whose cells are extremely unresponsive to the decidual stimulus; while as a rule they do not undergo during pregnancy any change analogous to that shown routinely by the cells of the endometrium, and more or less spasmodically by those of many other localities, they may, under exceptional circumstances, take part in a similar transformation, showing a well-marked decidual reaction in conjunction with either ectopic or uterine pregnancy.

Note.—Since the proof of the foregoing article was corrected, a second instance of distinct decidual reaction in the appendix in conjunction with normal pregnancy has recently come to my notice.

Mrs. L., aged 22, pregnant at about the sixth month, was operated on for an acute appendiceal attack by Dr. H. D. Beyea at the Gynecean Hospital, Oct. 7, 1913. The appendix was found greatly thickened and congested; it was closely bound down by a very short meso-appendix, but was not adherent to the uterus. There was no perforation, but there was a small amount of odorless, purulent exudate in the immediate appendiceal neighborhood. Following appendectomy and drainage the patient made an uneventful recovery, without disturbance of the pregnancy.

On microscopic examination of the appendix, all coats are seen to be thickened, and intensely infiltrated with round cells and polymorphonuclear leukocytes, presenting the characteristic appearance of an acute, diffuse appendicitis. Here again, however, the serous coat is the one most markedly involved: it is many times thicker than normal, edematous, and shows much congestion and inflammatory infiltration. Scattered here and there, chiefly in this instance in the deeper portions of the serosa, near the longitudinal muscle layer, are numerous small but very distinct and characteristic groups of the same large cells before described and illustrated. Although in this specimen none of the cell-groups are as extensive or prominent as in the first case, there rarely being more than half a dozen cells in a clump, and often only two or three, their appearance is so typical and distinct from anything else that there can be little doubt as to their significance. In many instances they are distinctly multinucleated, a condition not infrequently seen in true decidua.

It is rather significant that we have in this instance practically the same conditions as were present in the first case, namely, an appendix the seat of an acute inflammatory process, affecting most markedly the serous coat, in association with a well-advanced intra-uterine pregnancy.

2040 Chestnut Street.

INFANTILE PARALYSIS AFFECTING THE LOWER EXTREMITIES; ITS SURGICAL TREATMENT AND POSSIBILITIES OF CURE

A PRELIMINARY REPORT

E. P. MAGRUDER, A.M., M.D.
Clinical Professor of Surgery, Georgetown University School of Medicine; Associate Surgeon, Emergency Hospital.
WASHINGTON, D. C.

If we remember that, rickets excepted, infantile paralysis is the most prolific source of deformity, that 85 per cent. of these deformities affect the lower extremity and that in many instances the usual treatment is tiresome and tedious and extends over many years, then any short cut to the restoration of function in such cases is worthy of consideration. It will serve for contrast and comparison if for no other purpose.

My case is as follows:

History.—L. J., boy, aged 3, of Prince George's County, Maryland. Family history negative; father and mother, two sisters and a brother, alive and enjoying good health. None of these has experienced any illness similar to that of the patient, though there were other cases, I am told, occurring at the same time in that neighborhood. There are no evidences whatever of syphilis in the parents. Previous history: The child was breast-fed, enjoyed excellent health and was quite strong and active until nearly 6 months of age, when he was taken suddenly ill, with restlessness, fever and great irritability. He apparently desired to be let alone. Any movement, as an attempt to lift him, would cause him to cry out with pain. In a few days the mother noticed that he was quite unable to move his right leg, which lay limp and lifeless. After some weeks the child appeared normal again, except that the right lower extremity seemed completely paralyzed and remained so for two years. In May, 1913, the child was referred to me.

Physical Examination.—The child is fairly well nourished and normal in appearance except as regards the entire right lower extremity, which is in a state of apparently complete flaccid paralysis. The thigh hangs limp from the hip-joint, with slight flexion at the knee. There is marked difference in the measurements of the two thighs, legs and feet. The pointed toe of the right foot is typical. The reflexes are normal in the left lower extremity, while in the right, knee-jerk, Achilles tendon, Babinski and Kernig's signs are all absent. With the exception of the slight tonicity of the biceps, loss of power seems complete. If the child is made to stand on the sound leg, there is marked external rotation of the right thigh and eversion and abduction of the leg and foot. The capsule of the hip-joint is quite relaxed, and the head of the femur swings freely, partially without the acetabulum. The arc of rotation described by the trochanter is much exaggerated as compared with that of the sound side. The flaccid condition having existed for a little over two years, the only encouragement offered lies in the use of the biceps for transplantation, together with fixation of the ankle-joint.

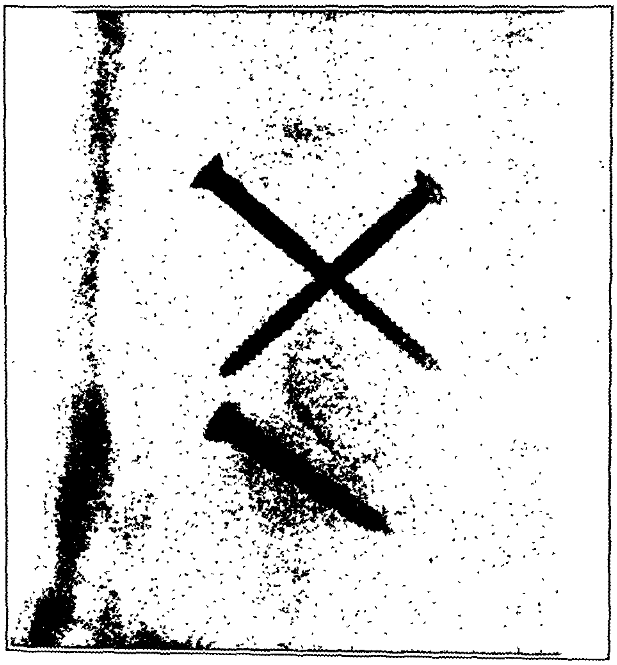

Fig. 1.—Fixation at ankle-joint; also scaphoid and cuboid bones. Anteroposterior view.

Surgical Treatment and Results.—The technic pursued consisted of the transplantation of the biceps tendon into the patella and a double fixation at the ankle-joint by means of three screws. With the foot in the corrected position at right angles to the leg, one screw was passed through the external malleolus, astragalus and calcaneus, another through the internal malleolus almost at right angles to the first, while a third screw was passed through the scaphoid and cuboid, fixing the key of the arch of the foot. The head of the femur was returned to the acetabulum and a plaster-of-Paris cast snugly applied from the foot to the costal margins and allowed to remain on for six weeks. The wounds healed by first intention.

Passive motion and massage were then instituted, and the weight of the body gradually applied to the foot, now firmly fixed at the ankle-joint. Minute instructions were given to the mother as to the training of the child to walk, and as an aid to this end a simple device of the foot-bridge effect, with hand-rails, was built outdoors close beside the house for daily exercise. The child held to the rails while his feet were, in the beginning, picked up and carried forward in the earliest attempts to walk. Two perfectly straight strings were laid on the ground between the rails, on which the child's feet were placed, so that he might be taught, so far as possible, to walk straight from the beginning; this was intended primarily to overcome the external rotation of the thigh, eversion and abducted foot-effect.

The power of the biceps soon manifested itself, changing its action from flexion to a very slight extension of the leg. The foot held firmly in the right-angled position. Improvement at first was very slow, and at times discouraging, but progress has continued steadily and without retrogression to date. The gain in strength to the leg, the increase in size of practically all the muscles, the marked growth of the child and the improvement of his mental and physical condition have been most gratifying. He can walk short distances, 50 or 60 feet, without any assistance whatever.[1] He can stand the weight of his body on the affected leg without its buckling beneath him. He enjoys his exercise in the open air and sunshine on his little foot-path with rails, and is quite delighted with the idea, which he has been taught to believe, that he is soon to be able to walk and play like other little boys. The external rotation of the thigh, with its eversion and abduction effect on the leg and foot, still persists, but I have as yet made no attempt to correct this, further than by the use of a little adhesive plaster running from the thigh above the knee on one side across to that of the other, which serves very well indeed for a temporary correction of the deformity. It gives him the wider pedestal on which to walk and stand. This is deliberate. In the earlier stages of the treatment, I believe that "suits of armor, bristling with screws and ratchets," if it is possible to do without them, are a decided disadvantage. They are an absolute hindrance to the freedom of growth and development and the early acquisition of strength to the affected limb, and of all considerations these are paramount.

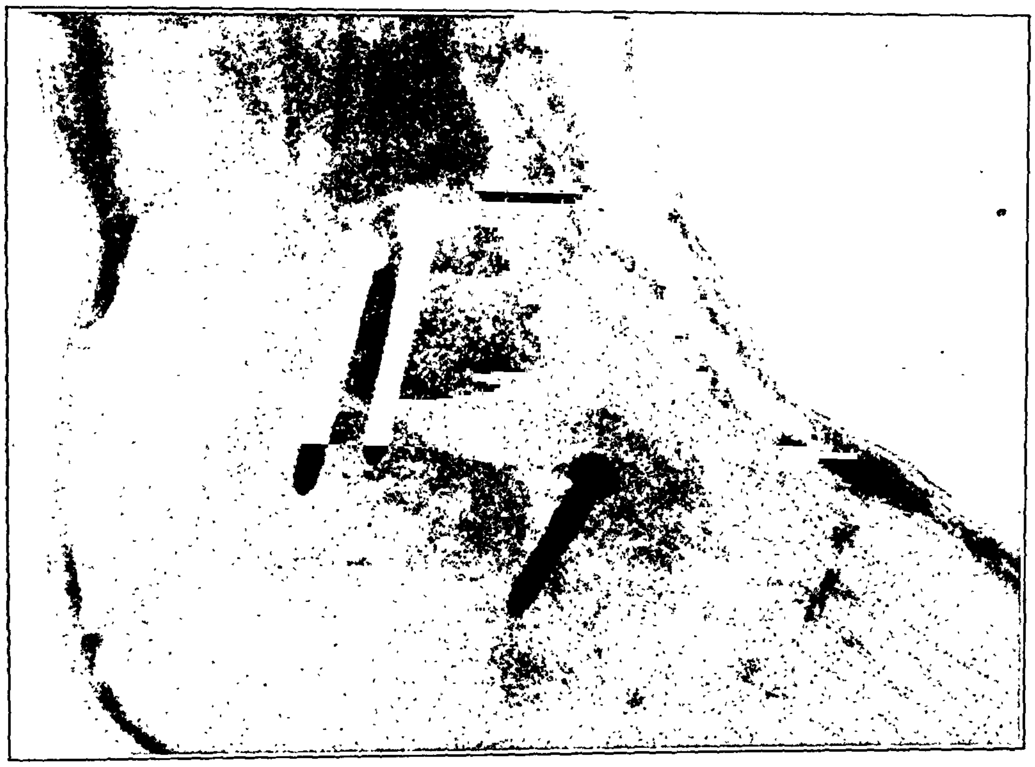

Fig. 2.—Fixation at ankle-joint; also scaphoid and cuboid bones. Lateral view.

POSSIBILITIES OF CURE

The operation to be successful must of course be followed by long and careful after-treatment, anticipating the sequence of events. The great error has been to assume that certain groups of muscles irresponsive to stimulation are lifeless, and that there is cell destruction in the motor area. On he contrary, actual cell destruction is nothing like so common as one might suppose, the condition often being transient and recoverable. Until this fact is accepted, the potentialities for recovery are not realized.

CONCLUSIONS

I am of the opinion that many cases of infantile paralysis regarded as hopeless are amenable to the treatment herewith suggested. The double-fixation method with tendon transplantation in paralysis of the lower extremity is, I believe, a valuable surgical asset. It is an effective substitute for arthrodesis, much less destructive of tissue, quicker in result, much surer and much simpler. Further, it does not permanently destroy the integrity of the joint or entail the extensive destruction of bone or cartilage, or both, and does not have to wait for the dictum of the "tenth year" in order to be effective. Again, these screws can be removed when strength to stand and muscular function are firmly established, thus restoring at least in part the integrity of the ankle-joint. At this late date of removal, recurrence is quite improbable. We may style the scaphoid and cuboid bones the key to the arch of the foot, and their fixation at this critical period with that of the ankle-joint itself unquestionably adds material strength to both. It is very effective in the prevention of toe-drop. That the screws may act as foreign bodies is an exaggerated fear. Foreign bodies become active only in the presence of infection. This has been conclusively shown by Lexer and Lane.

A double fixation is a double strengthening. It makes assurance doubly sure. The foot-bridge with handle-bars and strings on the ground running parallel is, I am persuaded, an effective device, the simplicity of which is its recommendation. The value of the open air and sunshine, in connection with the exercises as carried out with this device, is patent. The little patient early learns to become independent of another's assistance, and this independence stimulates and encourages self-confidence.

Properly directed, nothing else is quite comparable to exercising of the muscles by the patient himself. Self-reliance has no substitute.

The roentgenograms illustrating this article were taken by Dr. T. A. Groover.

The Farragut.

CAUSES OF ERROR IN THE DIAGNOSIS OF DISEASES OF THE JOINTS*

WISNER R. TOWNSEND, A.M., M.D.
NEW YORK

Surprise is often expressed by those who specialize in medicine at the number of erroneous diagnoses in the patients who are referred to them for treatment. The expert certainly should be able to make more correct diagnoses in the line of work that he is an expert in than one who is not specializing; but even among so-called experts errors are frequent and the correct diagnosis is sometimes never made, and in other instances many men are seen before the true nature of the disease is arrived at. Much could be written on the necessity for a correct diagnosis as preliminary to correct treatment, and in many instances errors in diagnosis involve serious results for the patient, as faulty treatment may actually render conditions worse; but this phase of the subject does not need to be elaborated. In this connection, however, I quote the following from Richard C. Cabot:[1]

> I wish in this paper to make three points: 1. A goodly number of "classic," time-honored mistakes in diagnosis are familiar to all experienced physicians because we make them again and again. Some of these we can avoid; others are almost inevitable, but all should be borne in mind and marked on medical maps by a danger-signal of some kind: "In this vicinity look out for hidden rocks," or "Dangerous: turn here, run slow." I shall enumerate some of these danger points presently.
>
> 2. Some common diseases are relatively inaccessible to diagnosis, no matter how carefully we are on the watch for them. From the study of 3,000 autopsies, I have begun to work out a percentage or ratio of accessibility for the commoner diseases.
>
> 3. Besides the classic and well-known pitfalls there are some less familiar to the profession and needing all the more, therefore, to be marked "dangerous."
>
> Most physicians believe that Pott's disease of the spine is easily recognized because of the "knuckle" in the spine, the pressure signs, muscular rigidity and secondary abscesses, but the difficulty is precisely in that group of cases which do not show these signs.
>
> Some of the most humiliating yet almost unavoidable failures of my experience have been made in cases which showed post mortem the lesions of Pott's disease. Only four of the seventeen cases that came to autopsy in this series of 3,000 post mortems were recognized in life. In ten of the thirteen "misses" there is "no blame to be attached to the official in charge." The diagnosis was not suggested by any of the facts at our disposal. The clinical picture was usually that of an overwhelming infection (miliary) which was called "septicemia from pelvic abscess" (really a psoas abscess), "meningitis," "acute uremia" (two), "septic scrotum," "otitis media with pyemia," "pneumonia" (two) and "septic hand with general sepsis."
>
> In two cases there was a slight kyphos which should have been noticed, but as it had been there for many years without change, it was ignored. In one case there was a gradual, even curve of the whole spine diagnosed by a skilful orthopedic consultant as spondylitis deformans.
>
> The ages of the thirteen patients whose disease was unrecognized were: 26, 51, 54, 81, 29, 44, 49, 53, 50, 64, 65, 45, 40. The average is fifty years. In the four recognized cases the ages were 34, 40, 34, 21 (average, 32).
>
> The moral is that we do not look or ask carefully enough for evidence of old vertebral tuberculosis in elderly patients, because we associate the disease with youth.

To those who specialize in orthopedic surgery it seems rather strange that so many errors should be made in the diagnosis of adult Pott's disease, but it only shows how necessary is a complete, careful examination of the entire body in cases in which the symptoms are not absolutely clear, because a complete examination of this kind would often reveal the true conditions present.

The percentage of correct diagnoses in Cabot's series varied greatly. The smallest was 16 per cent. in acute nephritis as compared with 92 per cent. in diabetes mellitus. Just what the percentage of error is in the diagnoses of diseases of the joints, it is difficult to state, but it has seemed desirable to bring together a few facts which might help those who have to make such diagnoses, to guard against errors that are avoidable. It is for that purpose that this article has been written, and in it no attempt will be made to print a list of all the diagnoses that could be made for any given condition or all the posible errors that are encountered in the diagnosis of any given condition.

The chief causes of error are:

1. Failure to obtain a proper history.
2. Failure to make a proper examination.
3. Failure to take a roentgenogram.
4. Failure to interpret the Roentgen findings properly.
5. Failure to use laboratory methods as aids to diagnosis.
6. Failure to adjust laboratory findings and clinical symptoms properly.
7. Failure by many physicians to realize their limitations—erroneous diagnoses due to ignorance.

The failure to secure a proper history is responsible for many errors of diagnosis, and the traumatic theory of the causation of joint-diseases was largely due to the failure to secure good histories, to ascertain the true facts or all the facts in the history of the patient with joint-disease. Many of these conditions occur in early childhood and in many instances the parents will attribute the symptoms to a fall, insisting that the child was perfectly well until then. A careful cross-examination, however, will show that night cries, intermittent pain and lameness may have existed for months but were not considered of any importance until the symptoms became aggravated as the result of some more or less serious traumatism.

A large number of the cases of Pott's disease in my experience have been attributed to the negligence of a nurse in allowing the child to fall, and the smallest of knuckles of the spine occurring in children of 4 or 5 may be ascribed to some traumatism of early life, or even pass unnoticed for a long time, or a careful history will show that the present symptoms had no connection with the traumatism which is held responsible for them. Systematic and careful histories should be taken in all cases of joint-disease and the teachers in the medical schools can do no greater service to their students than to impress on them the necessity for careful history taking.

It is essential if one is to draw any definite conclusions as to the causation of any given diseased condition, and a careful and well-taken history will clear up many obscure and involved conditions. Joint-diseases occur with, or are caused by, many infectious processes, and a good history will tell one whether the patient has or has had typhoid fever, scarlet fever, pneumonia, gonorrhea, syphilis, a new lesion, or an inherited one, a sore throat, and whether or not antitoxin was used, a tabes dorsalis, or any of the various forms of nervous disease accompanied by or followed by joint lesions.

---

* Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[1] Cabot, Richard C.: Diagnostic Pitfalls Identified During a Study of Three Thousand Autopsies, The Journal A. M. A., Dec. 28, 1912, p. 2295.

I have seen errors made in joint lesions of all of the before-named conditions in which a good history would have made conditions clear. For hospital or even private work history sheets or cards are invaluable and hasten history taking and assist in securing all of the desired facts relating to any given disease.

The history will also be of great help. If taken in connection with printed cards in causing the observer to think logically and not to lay too much importance on the trivial facts which are to the patient often the most significant, and thus made the most prominent in his details of the symptoms for which he applies for diagnosis or treatment.

At present the subject of heredity is not considered of so much importance as formerly, but it is of some value and that subject and the method of life and the surroundings in which the patient lives or has lived can be ascertained only by a careful history. Hereditary syphilis is very important, and knowledge can be secured in many instances only by careful and diplomatic cross-questioning. The history of mother and father should be taken separately, without knowledge of the other. Not only may the information be of value in arriving at a diagnosis, but it may also be of use in treating the parents and avoiding further inherited conditions.

As one sees patients in consultation one is also impressed with the fact that the physician who has a careful history, preferably a written one, to present is far less frequently liable to make an error in diagnosis than the one who has no clear idea of the history of the patient's previous condition. The failure to secure a good history is usually due to laziness or too great haste in the examination, although some physicians, like some lawyers, seem to lack the power to cross-examine properly. As most of those who contribute to medical literature draw most of their material from hospital wards rather than from private practice, they probably appreciate more fully the value of a good history than do those whose practice is exclusively among private patients; but the latter class of physicians could contribute fully as valuable material to medical literature if by a slight additional effort they would take histories of the most important of their cases, if not of all.

Most physicians can recall errors made in diagnosis from a failure to secure a good history of the case, and I feel that with the great tendency toward submitting everything that can be submitted to a laboratory test, the value of taking a proper history of every patient should be insisted on more strongly to-day than ever.

The failure to make a proper examination is also a frequent cause of errors of diagnosis. In childhood there is no excuse for lack of a thorough examination because children, even those in the second decade of life, are usually not close observers, and it is essential that they be examined with the clothing removed, and no objection is made to this procedure in either sex. In adults it is different. It takes time to dress and undress, and the physician is often hurried and yields to the wishes of the patient that only a partial examination be made. Many women also object to undressing for an examination, and sometimes much tact is required to secure their consent. The large number of errors in the diagnosis of Pott's disease referred to by Cabot were largely due to failure to make a proper examination, and his statement that "The moral is that we do not look or ask carefully enough for evidence of old vertebral tuberculosis in elderly patients" is interesting; but not all of these cases in adults are by any means old vertebral tuberculosis. Many are recent infections. To examine the spine of every patient applying for treatment would be absurd; but if it could be done in many instances it might be of value to both patients and doctor.

That Pott's disease in the adult is frequently overlooked, apart from Cabot's statistics, is a well-known fact. Two patients that I have referred to in another paper, in which the stomachs were washed out for varying periods by capable physicians, illustrate the failure to recognize a Pott's disease. The diagnosis of the same disease and of a lateral curvature by the dressmaker is not infrequent, because of failure of the physician to make a proper examination. The diagnosis of osteitis of the hip, knee or other joint and the overlooking of an active Pott's disease is not infrequent. The same is true of any active or acute disease. All attention is centered on it and other lesions overlooked, because they are not looked for. Enlarged and suppurating tonsils, carious teeth, pyorrhea, osteomyelitis of alveolar processes and jaws, swollen or bleeding gums, are all important in seeking obscure causes of infection.

I must acknowledge that to careless or hurried examination I have to credit most of my errors in diagnosis, and from conversation with colleagues I believe that it is the most frequent of all causes and that it is avoidable. To call attention again to this fact is therefore proper. Among the many new methods of diagnosis or aids in diagnosis is roentgenoscopy. It is of great aid in some instances and a great disappointment in others. A good roentgenogram may show something, while a poor one will show nothing. In early, incipient cases in which its aid is most helpful, even the best of roentgenograms often show nothing; but in case of doubt one should always be taken, if possible. It may show something and it will help in case of future trouble. It will show that everything possible was done to make an accurate diagnosis. In malpractice cases many arguments have been advanced by the attorneys to show that as there was a doubt as to diagnosis a roentgenogram should have been taken to clear up the doubt, and the failure to take one was "negligence." This is an extreme view; but as roentgenoscopy is so commonly employed, this aid to diagnosis should be more freely used.

Too much reliance must not be placed on the interpretation in roentgenoscopy. Experts differ wonderfully and no reliance should be placed on a poor roentgenogram in which one tries to see what he desires to see and no one else can see. Such a series of plates was sent me a few days ago with a diagnosis of osteo-arthritis of the spine. That was the diagnosis made by the physician in charge. As the consultant, I had asked for some roentgenograms, and they were made. The roentgenologist confirmed the diagnosis. The plates were shown by me to a number of men, and the only possible diagnosis that could be made from them was that they were attempts to take roentgenograms of the spinal column. Not even magnifying glasses and electric lights in boxes revealed any details to suggest the diagnosis made by the roentgenologist. This is not infrequent and may cause serious errors in diagnosis.

Another error is to misinterpret the findings in either a good or poor roentgenogram. Foci of disease are found where none exist and are overlooked when they are present. I have seen both conditions in which more careful examinations confirmed the facts. In one instance a focus of disease was shown on a print and no one could find it on the original plate; yet it really existed. The prints are usually not so satisfactory as the original plates.

Most plates make poor prints, and it is often impossible to see anything on a print. A blurring of a joint-surface may be taken for a beginning disease when it really is due to the fact that the patient moved during the taking of the picture. Occasionally a view in one plane will reveal facts that a view in another plane does not show. In developing the plate valuable data may be hidden or clearly brought out, and errors of photographic development may be responsible for false ideas as to what the roentgenogram really shows.

Negative findings should not be considered except very rarely. No one should ever make the mistake of ignoring clinical symptoms. Every question of doubt must be decided in favor of the existence of disease when the Roentgen findings are negative.

Errors due to placing reliance on roentgenoscopy are numerous and are encouraged by the statements of many Roentgen operators, that if disease is present the [illegible] ely show it. This is not founded [illegible] or thorough knowledge. Many early conditions cannot be detected by the Roentgen ray. In very fat persons clear pictures are the exception, and in early childhood soft bones an [illegible] lend themselves readily to clear and [illegible] between the normal and abnormal. Therefore, the caution is needed, do not rely too much on the roentgenogram; ignore it entirely if it is a poor one, or if no skilled expert has the opportunity to interpret it. What the average physician does not know about roentgenograms would fill many a volume, and even some experts have much to learn.

The laboratory aids to diagnosis are so important that they are being used more and more. In some instances they, too, fail to give us information in the early cases of joint-disease, so that one must, as in Roentgen-ray findings, be careful not to place too much reliance on a negative finding. The positive findings are of the greatest possible value. A positive Wassermann or a complement-fixation reaction in syphilis, a demonstration of gonococci, or the complement-fixation reaction, a positive tuberculin test or the presence of bacilli of Koch in sputum or in any of the discharges, and the presence of pneumococci and other bacteria make diagnoses possible of a definite kind that clinical symptoms can only suggest. The latter indicate disease of a joint, the former the nature of the infection. A leukocytosis may also be of value in differentiating different diseased condition. The laboratory findings must be interpreted intelligently. Not too much reliance must be placed on a tuberculin or Wassermann test in which the clinical symptoms "do not fit," so to speak. Such a case is the following:

> A positive tuberculin test was obtained in an adult with a low leukocyte count, a swollen ankle, a tender spot and swelling of lower third of tibia, a septic temperature ascribed to tuberculosis by the bacteriologist diagnostician, and loss of weight ascribed to tuberculosis by the family physician. There was a cough, but examination of sputum was negative. Roentgenoscopy at first was negative, and a diagnosis of osteomyelitis was made. Two weeks later Roentgen findings were positive, revealing a focus at the site of tenderness in the tibia. Operation was consented to. On the day before the operation there was a high leukocyte count: pus was found and evacuated; the temperature became normal; the cough disappeared; weight was more than regained, and the diagnosis of tuberculosis proved incorrect.

The general rule is that a high leukocyte count does not occur in bone tuberculosis but only in cases of infection by pyogenic organisms. The high count just before the operation confirmed the diagnosis. Other experiences of this kind occur to all and render caution necessary. The existence of two diseased conditions present in one person at the same time must be considered.

The prevalence of certain forms of arthritis varies greatly according to surroundings and conditions. Take for instance the table of Baetz,[2] who found in 100 cases of acute arthritis among negro laborers on the Canal Zone 63 cases of syphilitic arthritis, 28 of gonorrheal arthritis, 6 of undetermined arthritis, 2 of dysenteric arthritis and 1 of tuberculous arthritis. This is rather startling but easily accounted for by the conditions: a large male population made up of single men of low morals, with venereal diseases prevalent. No private practice in the United States would show the same proportion of causes of infection. All tests of laboratory type must be carefully interpreted, and the views of Craig[3] of the Army Medical Corps, express clearly the various interpretations that are to be given to the test, and close with these very pertinent remarks, which should be always followed by all who have to treat disease:

> For this reason the test should be made only in properly equipped laboratories by those who have received special instruction and who devote a large part of their time to this work. Under such conditions results will be satisfactory, but the interpretation of the test must always remain with the clinician. The laboratory report deals only with the result of the test, and it rests with the clinician to correlate this result with the clinical condition present.

Errors due to failure of physicians to recognize their limitations may in some instances be prevented by the sad experiences that sometimes follow serious errors. Many physicians are most conscientious in this respect, either declining to treat a given case or at once calling in an expert. A few others, some posing as specialists in some line in which joint cases are seldom seen, take such patients and continue to make the diagnosis of rheumatism for every joint lesion seen. For accurate diagnosis it would be well if the term "rheumatism" could be omitted entirely from nomenclature. Kenneth Goadby[4] says:

> The term "rheumatism," like many another medical word, has come to designate a multitude of diseases, and covers many sins of commission and omission in diagnosis. Omnibus words of this type are, no doubt, very useful, but tend to hamper exact description.

This class and the ignorant physicians who do not know a diseased joint when they see one are hopeless. No article ever written will reach them. Fortunately they are few in number and their number is becoming less each year.

125 West Fifty-Eighth Street.

ABSTRACT OF DISCUSSION

Dr. D. J. Griffith, Kansas City, Mo.: There are some other joints in which we are sometimes liable to make errors in diagnosis without the use of all the adjuncts of which Dr. Townsend has spoken. At any rate, the Roentgen ray is sometimes not available for use, and the patient comes with a diagnosis of other troubles besides the spinal one. This experience occurred to me in the case of a child, aged 10 years, who was brought to me with a history of knee-joint trouble It seems that, four or five years before, she had jumped and landed on one foot, instead of on both feet. Suddenly she experienced pain in the knee and just below it. She was brought to me after having had treatment for knee-joint trouble, of which she had had occasional attacks. At the tubercle of the tibia, but nowhere else, there was pain on pressure; she had passed over the point of temporary synovitis produced when she strained the joint. We found, on making a roentgenogram, one of those unusual cases that Dr. Osgood presented several years ago before the American Orthopedic Association. The tubercle of the tibia was torn off by the quadriceps tendon through some overexertion. The epiphysis had not been joined onto the diaphysis and had torn loose—Osgood-Schlatter disease.

[4] Goadby, Kenneth: London Practitioner, January, 1912.

Dr. Henry Ling Taylor, New York: There is one diagnosis that Dr. Townsend did not speak of that every orthopedic surgeon should be able to make, and that is the diagnosis of whether a roentgenogram is good or bad. The importance of this fact came out in practice when a medicolegal case was brought for diagnosis. The patient, a woman, was lame and had tenderness back of the hip, but the symptoms did not resemble any kind of arthritis of the hip. Her physician brought a series of roentgenograms to me and said: "Do you not see a cyst in these plates?" "No," I replied. "What do you see?" he asked. I said, "I see a poor roentgenogram." It was very cloudy. I insisted on having a series of good roentgenograms before I made a positive diagnosis. They showed no cyst but a button of bone divulsed, pulled out, just behind the obturator fossa. It was a unique case. I never saw or heard of one like it. This button of bone showed plainly in a series of five or six roentgenograms, taken in five or six different positions; this cleared up the diagnosis absolutely.

Dr. E. W. Caldwell, New York: I am glad to have an opportunity to express my approval of all that Dr. Townsend said about the danger of misinterpreting roentgenograms, and especially about the usual inaccuracy of hospital roentgenograms. For many reasons, which I shall not discuss at present, it is difficult to get good roentgenographic work in any hospital or similar institution. Sometimes it is a question of money. Often, however, it is a question of recognizing that Roentgen diagnosis is not photography. Many hospitals want to have this work done by a photographer. Although some photographers can be taught to make good-looking plates, we have all had plenty of occasion to know that the photographer's plate is not safe.

Dr. Reginald H. Sayre, New York: I often find that I do not get the true history of these cases until many months after I have been treating the patient, not on account of intentional falsification on the part of the patient, or on account of carelessness on my own part; but now and then, something will be said that will bring to light a fact that has been lost sight of absolutely.

There are one or two pitfalls in diagnosis that I have happened to notice, which I do not think Dr. Townsend mentioned. One is the possible error in mistaking anterior poliomyelitis, in the first few days of its course, for joint affections. I have seen three cases of this disease that were brought to me on account of a painful limp, and had almost all the earmarks of a beginning tuberculosis of the hip or of a beginning hip-joint inflammation. Being uncertain as to the diagnosis, I asked the child, in each instance, to come back again at the end of a week for further investigation; and at the second appearance the child showed distinct evidences of the existence of anterior poliomyelitis and subsequently went through the course of that disease. This is a fact worth bearing in mind.

I have also seen several hysterical knees (so-called), which depended on a reflex uterine lesion and disappeared after the uterus had been put in place and retained there. I have likewise seen a case of supposed tuberculosis of the spine that had been treated by a number of men, which was also due to a retroflexion of the uterus. There was spinal distortion, weakness in the leg and atrophy of the muscles on the affected side, all of which disappeared after replacement of the uterus. I believe that cases of this kind are more frequently met than we are generally led to suppose; and I can certainly agree with Dr. Cabot concerning the frequency with which Pott's disease in the adult is overlooked, as I have seen a large number of patients with this disease who had been in various hospitals and had been treated for various things. I remember one patient who had been originally referred to the hospital by the attending physician for Pott's disease; but there, she was not operated on for Pott's disease, but for a lacerated cervix. The patient was then sent back to the attending physician, but her symptoms continuing, she returned to the hospital later for another examination. On this occasion the hospital physician turned the patient over on her face, and found a knuckle in the spine, which had probably been there all the time. Failure to look for such things is probably the reason for not observing them more frequently.

THE PASSING OF THE FAMILY DOCTOR*

GEORGE W. GUTHRIE, M.D.
WILKES-BARRE, PA.

Lowell says, "Time makes ancient good uncouth." The whole trend of modern thought is to look for a new and better way. We travel, literally, in chariots with horses of fire. Jules Verne's dream of "Around the World in Eighty Days" has been more than realized and the stories of the Arabian Nights are equaled by the every-day events of common life.

Even our sentimental life has changed. The beautiful story of Uncle Toby and the fly that was an inspiration to our boyish imagination and the picture of the kindly old man opening the window and saying, "There's room enough in this world for both thee and me" has been changed to the slogan "swat the fly." We have come to agree with Cowper in reference to the lower animal's that

> If man's convenience, health or safety interferes
> His rights and claims are paramount and must extinguish
> theirs.

But in no realm of human activity has the advance of modern thought caused such changes as in the practice of our profession. In the past one physician, the family doctor, was deemed competent to meet all the exigencies of life requiring medical aid; he was physician, surgeon, obstetrician, oculist and pediatrist.

President Wilson,[1] in his admirable address of welcome as governor of the state of New Jersey, to the American Medical Association in Atlantic City on June 15, 1912, said:

> I believe you will agree with me that one of the things to be regretted in our modern time is that we have been obliged to specialize our professions to so great a degree, because in proportion as the medical profession is specialized, for example, the old family physician disappears. I remember going over in my memory a single year of my family life with my children when they were small and finding that I had called in consultation thirteen different specialists. There was no ill luck in the thirteen because it all came out very happily. But where I had summoned thirteen specialists, my father would have summoned one family physician. My father would not have got as good advice as I got, and yet I lived through it. But every time he sent for his doctor he was sending for a personal friend. He was sending for a man who had his confidence in a peculiar degree. He was sending for a man who walked the paths of life with him as a com-

---

* President's Address, read before the Lehigh Valley Medical Association, July 17, 1913.

[1] Governor Wilson's Address of Welcome, The Journal A. M. A., June 15, 1912, p. 1913.

rade and confidant. There was something very vital, there was something very useful in that relationship, and although we have certainly yielded only to necessity, it is unfortunate that we should have been obliged to specialize so much as we have and therefore it is necessary, it seems to me, if you will permit me to suggest it, that we generalize our sympathies.

It is self-evident that the work of the profession must necessarily be specialized. The field has become so vast that one mind can cover it only in a general way. But granting that it may require thirteen or twice thirteen specialists to represent all that is known in medical science and medical practice, it seems to me that it will be an unfortunate day for society when the honored office of family physician has become obsolete. I know that it is now a common practice for people to act on their own volition in the choice of a specialist. This is unfortunate. It were better by far that the patient act under the advice of his physician, even in the choice of a hirsute specialist or a corn-doctor, for I have known more than one case of serious infection to arise from a dirty corn manipulator, and many a bald head comes from ill-advised use of hair-restorers.

In this respect, as in many others, people are not able to decide wisely for themselves. An advertisement in a newspaper or the advice of some layman may be followed. The optometrist claims that he can treat all ailments pertaining to the eye; the osteopath has the effrontery to undertake to cure anything and everything, and so on through the whole range of human ills: there are pretenders whose true status can only be known by the intelligent, conscientious family physician, consequently he should be consulted in the choice of a specialist; first, because by his intelligent advice the patient will choose a specialist worthy of his confidence, and secondly, because the cooperation of the family doctor and the specialist will result in the patient's benefit, no matter what the ailment may be. The family physician, by his knowledge of the patient's family history, environment and habits, can aid the specialist who should return the patient to the personal adviser for the after-treatment and care.

There is no doubt that never in its history was our profession so competent and so willing to give aid and relief to the human family as at the present time. Indeed, the whole tendency of society is toward a broader humanity, which means that the best that the profession can give, the best that charity can furnish, should be shared by everybody.

The work of the visiting nurse and the hourly nurse, and that of the social service worker has carried the charity of the hospital and of the profession in a most intelligent manner to the needy and deserving. Indeed the humane offices of the well-equipped charity hospitals and the services referred to give the best to the poor and dependent. The wealthy can command this, either in their homes or in private hospitals; but how about the middle-class man, the man who cannot, who will not make himself an object of charity, but who has not the means to command the best the profession can give in all the special lines he may need?

Let me cite a possible example: A self-respecting artisan, accountant or teacher, earning $75 to $100 a month, takes his wife to a physician for advice and treatment. It is found as the examination proceeds that the services of an oculist, a cystoscopist, a roentgenologist, a pathologist and probably other specialists are necessary for a complete diagnosis. How is it possible for this patient to obtain this service in the most complete manner as the profession now operates and have the charges remain within his ability to pay? The poor and the wealthy, as noted above, have the best the profession can give them; why not the eminently respectable and worthy middle class of our people?

Dr. Richard Cabot, in an address before the Medical Alumni of the University of Pennsylvania, April 18, 1913, in referring to the need of this class of better medical service, advocated the grouping of medical men representing the several specialties, thus securing for the patient what he called a "group diagnosis," which should be furnished at a figure within his ability to pay. He referred to clinics in which this feature was present. The most notable example is the Mayo clinic at Rochester, Minn. A patient at that clinic can have, in addition to an ordinary diagnosis, physical exploration, etc.: (1) examination of nose, throat, antra and sinuses; (2) examination of eyes and eye-ground; (3) blood-counts, hemoglobin estimates, also coagulation examination for malarial organisms; (4) sputum examinations, also feces, Wassermann, complement-deviation test, vaccines and other parasitic and bacteriologic examinations; (5) test-meals; (6) fluoroscope-bismuth plates of gastro-intestinal tracts and roentgenograms generally of chest; (7) kidney, skull, pelvic and long bones; (8) proctoscope work; (9) genito-urinary diagnosis, including also cystoscope, functional renal tests, etc.; (10) fresh or preserved tissues for pathologic diagnosis.

About fourteen thousand patients attended this clinic in the year 1912, all of whom were examined and a careful diagnosis made in each case. About half the number were found to present conditions requiring operation—in exact figures, according to the report for that year, 7,053. Dr. Graham informs me that this number, about 50 per cent. of the patients appearing at the clinic, is much larger than in the earlier days of their work, in which the number recommended for operative treatment was not over 25 per cent. This is due in part to the increased diagnostic ability of physicians and to the greater diagnostic aids that have so recently multiplied. All these patients, however, are carefully examined and charged a fee for services, according to their ability to pay, which may be as low as from $10 to $15, or may be as high as $500, if the patient is wealthy.

This combination of medical men, representing the various specialties, is, to a greater or less degree, possible in every community. Call it what you will, the department-store idea applied to medicine, or any other name, if the end accomplished helps financially to bring the best aid of the profession to the middle class, it is justifiable; aye, more it is a necessity.

This grouping of medical men representing special lines of study and work is the only way in which the middle class can command the best services, unless they pauperize themselves and enter charity hospitals. Patients referred to these groups can return for treatment to their family doctors or personal advisers, with a scientific diagnosis, or they may enter hospitals which should be so managed that the expenses may be within their financial possibilities. Hospitals managed by religious orders, in which the nursing and care of the patients are largely in the hands of women who consecrate their lives to this service, are entitled to consideration and respect. We have splendid examples of such hospitals in the German Hospital of Philadelphia and St. Mary's Hospital at Rochester, Minn.

Granted that such a plan is feasible, that the best specialists associate themselves in groups for diagnosing and treating patients; does this do away with the family physician? Not in the least. The family doctor in this proposed scheme must be an up-to-date man. His knowledge must be general and accurate, he must keep in touch with advanced professional ideas, he must know that an operation for appendicitis performed within the first twenty-four hours of attack will, in all probability, cure the patient in one week, and that if a delay of forty-eight hours occurs, the results are much more serious and the convalescence prolonged into weeks or months. He should know that 80 per cent. of the growths in the mammary glands of women become malignant and that such patients should be referred to a surgeon. He must know that an inflammatory condition of the eye may be conjunctivitis, iritis or glaucoma; he must know the dangerous character of the latter two diseases, and especially that an acute inflammation in the eyes of the new-born is most dangerous and that all these cases demand the care of a specialist. He should know his own limitations. Weelum MacLure, the doctor of Drumochty, knew that he could not give Tammas Mitchell's wife the treatment that was necessary; he knew that she required the services of a surgeon and Sir George, the queen's surgeon, was called and saved the woman's life by operation. Dr. MacLure was equal to the terrible emergency that came to Burnbrae's family, when the boy's hand was mangled in the threshing machine. He amputated the hand and saved the boy, "the very look of him was victory that day." He knew how to treat Saunders, when the fever ranged above the danger-point, for he and Drumsheugh carried cold water from the spring, "dooked" the patient and thus reduced the temperature, but when Mitchell's wife suffered from what was probably a pelvic abscess, he summoned a surgeon who saved the patient to her husband and children.

Much has been said lately of lodge practice and medical insurance. The lamented Dr. Bristow[2] stated that 50 per cent. of the population of the United States earns less than $500 each annually, that 20 per cent. earns as low as $200 each annually. It is self-evident that this meager income can at best buy only the barest necessaries of life, and that when sickness comes there is nothing to do but to become objects of charity in hospitals, or, by combination in fraternal organizations or beneficial societies with insurance features, to secure the services of a physician in their homes at a low rate.

The Judicial Council of the American Medical Association, of which I have the honor of being a member, has been struggling with the question of lodge practice and the chairman, Dr. Alexander Lambert, in the report to the last meeting of the American Medical Association held at Minneapolis in June, said:

> No one questions the right of any man to take out a health policy in an ordinary health insurance company. No one questions the right of that man by this policy to pay from $60 to $300 a year as an insurance against the possibility of *accident or disease and* possible temporary or permanent invalidism occurring to him in the work peculiar to the medical profession. How then *does this* differ from the *dollar a* year that members of the lodges *and* societies pay for the privilege of obtaining medical services and care in accident and sickness, if these misfortunes come to them? There is no difference in principle; *there is no* difference in the economic necessity of it. As such it should be recognized and treated. The question comes down then to the designation of the weekly or monthly income at which this should be treated as an economic necessity and above which it is an economic luxury. These economic conditions have been reached in the countries of Europe and have recently caused a vigorous struggle between the medical profession and the government in England. It is useless to struggle with "whereas's" and "resolutions" against these economic facts. It is time for the American Medical Association and its constituent bodies to look these facts squarely in the face, to accept them and, by instituting fair control, to see that justice is given to the members of their profession and that an equal social justice is given to the poor whose necessity demands this sort of service.

After everything possible has been said of the division of medical practice into specialties, of the necessity of the poorly paid combining to secure cooperative insurance and medical treatment in their homes at a low rate, the field of the family doctor is still a large one and the demand for his services will ever remain, and a sorry day it will be when his influence has been lost and his interest forfeited.

And now, in conclusion, let me repeat that the day of the family doctor has not gone by. The individual, the family, need his wise counsel, his personal, friendly interest as much now as ever before. Our medical schools are wise in training men in general medicine in all its departments, that they may have intelligent perceptions of every phase of human suffering, and may be able to advise and direct their patients to the best sources of relief. The interest of the specialist must necessarily be general and lack the sympathetic, personal element mentioned by President Wilson as belonging to the family physician.

Just as the religious adviser is needed in spiritual matters or the lawyer in the affairs of business, so will the medical adviser, the family doctor hold his place in the American family. Our great country is a nation of families and so long as the family life remains the predominant feature of our social organization, just so long will the family doctor be a necessity, and his services be demanded, and it will be for him

> To give what none can measure, none can weigh,
> Simply to go where Duty points the way—
> Faith, honor, duty—duty calmly done
> That shouts no self-praise o'er a victory won—
> One bugle note his battle call,
> One single watchword—Duty—that is all![3]

The Coordination of the Specialties.—After all, if unity and coordination are to be continuously realized in the profession at large, some one must be found there particularly standing for them. There never has been, is not, and never *will be* other than one such agent. He is the family *doctor.* No matter what may be his crudities, weaknesses *and* inconsistencies, he is the only material we have out of which to make a sovereign. *And* it is he who must save the day if medicine is to remain a profession instead of becoming an *association* or *confederation* or congeries of trades, and if order and symmetry are to prevail therein. . . . *If* such be his high *destiny* let him get himself ready for it. The trouble with him has been that he has not apprehended his proper mission, or the real basis of his strength, worth *and* dignity. He has been trying to do detail work in all quarters, when it is his business chiefly to oversee. He has been panting along after the specialists and succeeding merely in playing second fiddle to them, when it is his prerogative to marshal and command them. He has well-nigh split his "one small head" in his endeavor to be an *authority* in everything, when from the nature of the case, he can be an *authority* on nothing but humanity.—W. B. Konkle, M.D., in *New York Medical Record.*

VERRUGA PERUVIANA. OROYA FEVER AND UTA

PRELIMINARY REPORT OF THE FIRST EXPEDITION TO SOUTH AMERICA FROM THE DEPARTMENT OF TROPICAL MEDICINE OF HARVARD UNIVERSITY

RICHARD P. STRONG, M.D.
Professor of Tropical Medicine, Harvard University
E. E. TYZZER, M.D.
Assistant Professor of Pathology, Harvard University
CHARLES T. BRUES, S.M.
Instructor in Economic Entomology, Harvard University
BOSTON
A. W. SELLARDS, M.D.
Instructor in Clinical Medicine, Johns Hopkins University
BALTIMORE
AND
J. C. GASTIABURU *
Director Municipal Laboratory of Hygiene
LIMA, PERU

The expedition was undertaken for the purpose of investigating certain obscure forms of tropical disease in South America, particularly verruga peruviana, as well as with the idea of collecting material to be used for the instruction of students in the various courses of tropical medicine to be inaugurated at Harvard University in November of the present year. After proceeding to Colon and Panama we continued down the west coast of South America to Buenaventura, Colombia, and thence to Guayaquil. In Buenaventura, Guayaquil and the vicinity, material relating to biting insects, animal parasites, caraate, frambesia, plague, malaria and particularly yellow fever was collected. The studies carried on in relation to these localities will be considered in the complete report of the expedition to be made at a later date.

From Guayaquil we proceeded to Peru, where at Lima, and in a number of the mountain towns in the interior, the major portion of the work of the expedition was carried on. In Peru the diseases particularly investigated were verruga peruviana, Oroya fever and uta. Peru, in a number of ways, may still be spoken of as a land of mystery. The unusual climatic conditions which prevail in certain parts of this country—situated as they are so near to the equator—have undoubtedly exerted an influence in producing in some respects a very unusual flora and fauna in these regions; therefore it is not so surprising, perhaps, that unusual diseases should be encountered in these localities.

VERRUGA PERUVIANA AND OROYA FEVER

From the remotest historical times the inhabitants of Peru are said to have suffered severely from this obscure disease. Over four centuries ago, during the reign of Inca Huayna Capac, thousands of lives were swept away, supposedly from this malady; and it is related that during the sixteenth century a quarter of the army of Francisco Pizarro perished from it. References may be found to the disease in Peruvian writings of the seventeenth and eighteenth centuries, and from 1843 to 1871 a number of additional papers relating to it were published, among which may be particularly mentioned those of Odriozola[1] in 1858, and of Dounon in 1871. In 1870 a severe outbreak of fever took place among the workmen building the Central Railway between Lima and Oroya, and it is estimated that at least seven thousand lives were lost in the verruga zones. At this time the complaint received the name of "Oroya fever," although it appears that it was not contracted in Oroya itself. In 1906, out of a force of two thousand men employed in tunnel work for the Central Railway, two hundred are known to have died of the disease. Previous to 1885 there ensued some discussion as to whether Oroya fever and verruga were related to one another, or whether the latter was a distinct disease. Aug. 27, 1885, Daniel Carrion, a medical student in Lima, and a native of Cerro de Pasco, Peru (a town situated in the mountains far above the localities in which the disease abounds), attempted to solve this problem by vaccinating both his arms with blood from a verruga tumor. It is related that twenty-three days later he began to suffer from Oroya fever, from which he died, October 5. From this experiment the conclusion was drawn by Peruvian physicians that verruga and Oroya fever were only different stages of the same disease, and this is the opinion which has been held by practically all of them up to the present time. In honor of Carrion's attempt to throw light on the nature of the disease, the febrile condition which has been regarded as the first stage of the malady is now generally known in Peru as "Carrion's fever." Although it has been stated that Carrion during his illness kept notes, and gave a minute description of his symptoms to his companions, unfortunately it appears that none of these were preserved and published. No accurate record of Carrion's case is available, and no necropsy was performed. It has been asserted since that he died of typhoid fever or of a more acute form of septicemia.

In 1901 and 1902 Barton[2] performed extensive bacteriologic investigations, and concluded that in the blood and organs at necropsy of persons dying from Carrion's fever a bacillus was present which, though similar to *Bacillus coli communis*, could be distinguished from it. The organism was said to cause either a fatal septicemia in animals, or a verruga-like eruption of the skin. Biffi and Carbajal[3] and Tamayo and Gastiaburú[4] investigated this bacillus, and reported that it was present constantly and in abundance in persons suffering from Carrion's fever, and was agglutinated by their serum, but was absent from persons suffering from verruga peruviana without fever, whose serum also showed no agglutination of this bacillus. They identified the organisms isolated as belonging in the paratyphoid group. They were unable to confirm Barton's results as to the production of a skin eruption by the bacillus, and concluded that it is not the specific agent in Carrion's disease, but is a secondary invader in verruga, and gives rise to the symptoms of a form of typhoid fever, which disease constitutes the *fiebre grave* of Carrion.[5] In 1903 Biffi[6] and Gastiaburú[7] noted in stained preparations of the blood the presence of granules in the red blood-cells which stained readily with the basic anilin dyes. The form and structure of these bodies was that of a coccobacillus or of irregular granules. In 1905, before the Sociedad Medica Unión Fernandina, Barton[8] described in the red blood-cells of two persons sick with severe malignant fever elements similar in morphology to bacilli. In 1909 he noted the presence of these elements in stained blood-specimens in fourteen additional cases and expressed the belief that they were protozoa and probably the specific agent of the infection. In 1909 Gastiaburú and Rebagliati[9] observed the bodies described by Barton and stated that they were probably protozoa and might be regarded as the pathogenic organism in Carrion's disease. Later, Mayer,[10] Gastiaburú and Rebagliati,[11] Monge[12] and several other observers have been inclined to believe that the bodies described by Barton were products of cell degeneration. Nocolle,[13] Letulle,[14] Escomel[15] and Galli Valerio[16] found acid-fast bacilli in the lesions of the skin from patients with verruga. Darling,[17] whose studies are based on a necropsy made in Panama the day following the death of a patient with verruga, complicated with tuberculosis, suggests that the acid-fast bacilli previously described were really tubercle bacilli occurring in cases complicated by tuberculosis. Still more recently Gastiaburú and Rebagliati[10] have found in the liver and skin lesions of a verruga patient in the eruptive phase certain bodies, at times endoglobular in leukocytes and other cells and at other times free, which from their staining reactions and morphologic appearance they regarded as probably organisms of the genus *Leishmania*. Rebagliati also found certain endoglobular bodies which he considered to be remnants of nuclear disorganization of the erythrocytes, which suggested that Barton's bodies might be chromatin filaments, segregated from the nuclei of the erythroblasts.

According to the generally accepted opinion among the physicians of Peru at the time of our arrival in Lima, the disease verruga peruviana in the severe type begins with an initial stage known as the *fiebre grave* of Carrion, which is characterized by a fever which lasts from fifteen to thirty days, profound anemia, prostration and a high mortality. If the patient does not die in this stage the fever begins to abate, and the eruptive, or verruga, stage commences. If the eruption is generalized and abundant, then it is stated that the patient is sure to recover. In the chronic or mild type of the disease, which is said to comprise the great proportion of the cases, there is moderate fever of intermittent or remittent type, and pains in the joints are common; more or less anemia is present. The eruption is said to be the culminating phase in both forms, and it appears under various types which, according to the special characteristics they reveal, are termed "miliary," "nodular" or "mulaire."

Our investigations concerning the etiology of verruga peruviana and of Oroya fever were carried on in the Municipal Laboratory of Hygiene, and in the hospitals of the city of Lima, and in the mountain towns of Santa Eulalia, San Bartolomé, Surco, Cocochacra and Matucana, and in the vicinity of these towns. In the present report it is merely the intention briefly to enumerate some of the results of these studies. From our investigations we have concluded that verruga peruviana and Oroya fever represent two distinct diseases. The former is due to a virus which may be transmitted to animals by direct inoculation and which produces definite lesions in them, whereas the latter is due to an organism parasitic in the red blood-corpuscles sufficiently distinct from the other hematozoa to be placed in a new genus. So far this organism has not been successfully transmitted to the lower animals. The parasite which we consider to be the cause of Oroya fever produces in man fever and in severe infections a rapid and very pernicious form of anemia, which results in extreme prostration and frequently in death. In one of the cases studied by us, which resulted fatally, the red blood-cells numbered less than one milliom per cubic millimeter. At the necropsy in this case, in addition to the evidences of a very severe anemia, the spleen was enlarged and showed hemorrhagic infarctions. No other organism to which death could be ascribed was found present. In this uncomplicated case there was no eruption of verrugas. Both intravenous and intratesticular inoculation of rabbits, as well as intravenous inoculation of a monkey, with large amounts of defibrinated blood from severe Oroya fever cases did not produce any noticeable results; and the parasites observed in the blood in the cases in man were not found in the blood of the inoculated animals. The parasites were observed in the blood in the cases in man both in fresh and in stained preparations. According to Barton,[18] the bodies observed by him could not be detected in the fresh blood, and it has been stated that their refractive index must coincide with that of the erythrocyte. The organisms, we observed, consisted of rod-like bodies and more rarely of rounded ones, situated within the red cells.

Fresh Blood Preparations.—Although in fresh blood preparations the organisms are frequently difficult to detect, and at times appear to lie deep in the substance of the red blood-cells, nevertheless with good illumination and an oil-immersion apochromatic objective, they may at times be distinctly observed. In form they are rounded or rod-shaped, though the rods are not always straight in outline. The rods measure approximately from 1.5 to 3 microns in length and the rounded bodies from 0.5 to 1.5 microns in diameter. In severe infections, red corpuscles in almost every field of the microscope are invaded by the parasites, and numbers of both rounded bodies and bacillary forms are frequently observed in a single cell. The organisms are endowed with definite motility, which amounts to slow transition and is totally distinct from that of pedesis. To observe this it appears advisable previously to warm the slide and to examine the preparation immediately after it is made. In red cells in which several of the parasites are visible it is easy to observe their frequent change of position within the cell and with reference to one another. The rod-shaped forms were observed to glide slowly in the direction of their long diameter and to exhibit a slight bending in their transition in the red cell, and at times both these and the rounded bodies might be seen to occupy in turn all portions of it. They were never observed to appear as cross forms, as distinct spirals or markedly S-shaped. Occasionally at the two poles of the organism a dot or bead-like appearance was observed. On account of their small size the rounded bodies are more difficult to describe in fresh specimens and it can to the statistics of Peruvian physicians, in a large percentage of verruga peruviana cases the blood examinations shows an infection with malarial parasites; and in one of the twenty-two cases of verruga peruviana which we studied a concomitant infection with Oroya fever was observed.

[18] Barton: Quoted by Darling (Footnote 17).

It is quite evident that verruga peruviana represents an entirely distinct disease, and that it is not a form of frambesia or of syphilis. In our studies both of these diseases were excluded. The disease owes its origin to a virus which produces on intratesticular inoculation into rabbits a characteristic local lesion. The incubation period varies in rabbits from ten to twenty-two days. So far fifteen rabbits have been successfully inoculated, and the virus is now in its third transplant in these animals. In dogs and monkeys, cutaneous and subcutaneous, and sometimes intraperitoneal, inoculation has given rise after from eleven to seventeen days to localized lesions, which sometimes resemble closely those observed in man. The virus is also in its third transplant in monkeys. Jadassohn and Seiffert,[23] Mayer, da Rocha-Lima and Werner[24] have also been successful in single cases of verruga peruviana in transmitting the virus to monkeys.

The Wassermann reaction was negative with one exception in the cases of verruga which we examined. Moreover, no fixation of complement could be obtained when a specific antigen was substituted for the antigen used in the routine Wassermann reaction.

The biologic examination of an extract prepared from a cutaneous nodule in a case of verruga showed the presence of a hemolysin which was active in relatively high dilutions. The properties of this hemolysin are still under investigation.

Having become convinced that Oroya fever and verruga peruviana were two entirely distinct diseases, and having secured through the kind assistance of Dr. Matto, professor of bacteriology in the University of Lima, a volunteer (a Chilean), we made a direct inoculation from two cases of verruga peruviana. A portion of a skin lesion from each of the two patients of verruga was removed, and within twenty minutes of the time of this operation the skin of the normal person over the left shoulder was thoroughly scarified, and a portion of the nodules removed from the verruga patients thoroughly rubbed into the scratches. The vaccination scratches healed entirely at the end of about ten days, and the skin appeared normal. On the sixteenth day two small groups of cherry-red papules at the end of some of the vaccination scratches appeared, and a few days later another small group became visible. These increased slowly in size until the thirty-fifth day, when two of the groups were removed. The blood examination of the vaccinated person never revealed any of the parasites observed in the blood of Aroya fever cases, and no appreciable anemia developed. No generalized eruption occurred and the person was in good health at the time of our departure from Lima. It seems hopeful that by using the virus of verruga peruviana after one or two passages through the rabbit's testicle, or possibly through several more in monkeys, a successful means of vaccination against verruga peruviana may be obtained.

UTA

Uta is a disease which has existed in Peru since prehistoric times, and the lesions of which have been supposedly depicted on the ancient huacos of the Incas. It has been stated by various authorities that the disease represented a form of syphilis, or one of prehistoric leprosy, or a special form of lupus vulgaris. In recent years two extensive monographs on the subject have appeared from Peru, one by Tamayo[25] in 1908 and the other by Palma[26] in 1909. Tamayo regarded the disease as a special form of lupus vulgaris. Palma concluded that it was a specific disease, which was not to be confounded with other South American maladies, and that it was not a form of tuberculosis. The disease was observed by Past-Assistant Surgeon Perry, United States Public Health Service, in his travels through Peru; and by Surgeon-General Blue who, in conversation with one of us prior to our departure, mentioned its occurrence among the schoolchildren of Surco, one of the Peruvian mountain towns in which the disease occurs abundantly. In both Surco and Otao (the latter town deriving its name from the prevalence of the disease there) a large proportion of the inhabitants are either afflicted with the disease, or show the disfiguring scars which have resulted from a previous attack, on the face, arms or legs. From our investigations we were able to show that uta is due to a species of Leishmania. The flagellate stage of the organism has been obtained by us, and animals have been successfully inoculated from a human case.

ACKNOWLEDGMENTS

In connection with the investigations of the commission we wish to express publicly our thanks, particularly to the Corporation of Harvard University for generously providing funds for the maintenance of the expedition and to the dean of the Harvard Medical School and the dean of the Graduate School of Medicine for their interest and assistance in the organization of the expedition; to the United Fruit Company of Boston for generously furnishing us with transportation from New York to Colon and return; to the Royal Mail Steamship Company and the Pacific Steamship Navigation Company for furnishing us free transportation from Balboa to Guayaquil and from Callao to Balboa, and to the Panama Railroad Company for courtesy in regard to handling our baggage across the Isthmus. We also wish to express particularly our gratitude to Mr. J. W. Blaisdell, assistant manager of the Central Railroad Company of Peru, who very generously on several occasions furnished us with special railway facilities in our studies carried on between Lima and Oroya, and to Dr. H. F. Bailey, Cerro de Pasco Railway, for many kindnesses during our expedition from Oroya to Cerro de Pasco. To the following physicians and officials we wish to express our grateful acknowledgment for many kindnesses and for assisting us in obtaining material in connection with our studies: Drs. Deeks, Perry, Caldwell, Darling and James in Panama; Dr. Parker, Consul General Baker and Dr. Pereja and other officials of the Board of Health in Guayaquil; to President Billinghurst of Peru and to the American minister, Mr. Henry Clay Howard, the introductor of ministers, Mr. Cisneros, and Drs. Odriozola, Arce, Grana, Barton, Hercules and Matto in Lima. We also wish to express our great appreciation of the very valuable assistance rendered us by Dr. J. C. Tello, director of the ethnologic museum, Peru, in facilitating our obtaining material and in assisting us in making arrangements in regard to some of our investigations. Without Dr. Tello's assistance some of our investigations would probably not have been brought to so successful an issue as they were. A more detailed statement of our appreciation of the kindness shown us by a number of the above-mentioned physicians will be made in the complete report of the expedition. Finally, we wish to express our deep appreciation of the efficient services rendered by Miss Nora Dwyer, who accompanied us as secretary on the expedition.

only be stated that they change their position within the cell.

Stained and Fixed Preparations.—The rod-shaped forms measure approximately from 1 to 2 microns in length and from 0.2 to 0.5 microns in thickness. They are usually curved, and occur singly or end to end in pairs, or in chains of three, four and five. V forms, probably representing dividing organisms, are frequent. When numerous they often lie parallel to one another. Cross forms are rare and may be due to organisms being superimposed; Y forms are also infrequent but not numerous. The ends of the rods in stained preparations are intensely colored. Single free rods show a deep red or purplish granule which may be of the nature of chromatin and gives the appearance of a swelling at one extremity, the rest of the rod having a more bluish tint, sometimes deepest at the opposite end. Other rods may be blue throughout or have the deeply stained granule at both ends, while others are beaded with blue or deep reddish granules.

The rounded forms are roughly from 0.3 to 1 micron in diameter, the larger ones being considerably thicker than any of the rods. The greater proportion of these, although rounded, are slightly oval or pear-shaped; some are considerably larger than the rods and the deeply stained granule is proportionately larger and is likewise differentiated from the more blue-tinted cytoplasm. They occur singly or in groups which suggest previous division.

The red cell may contain from one to as many as thirty of the above-described elements. Nucleated red cells at various stages of development are found infected. From the anemia which occurs in this infection, it is to be presumed that the red cells containing the parasites are ultimately destroyed.

CLASSIFICATION

From the description given above it is evident that we have to do with a species of organism possessing some of the characteristics described for the *Anaplasmata* or of the *Theileria,* but also differing widely in some respects from the characteristics described for each of these genera. The rounded bodies resemble the *Anaplasmata* as first described and illustrated by Theobold Smith[19] in 1903 and later by Theiler[20] in their form and size and in the fact that they apparently consist entirely or almost entirely of chromatinic substance. Although the bacilliform or rod-shaped bodies predominate in our specimens, their appearance and staining reactions are considerably unlike those of the rod-shaped bodies observed in the *Theileria,* and cross forms have not been observed. Moreover, their movements are unlike those of the *Piroplasmata.* While the organism at first sight may be regarded from its morphology alone as a species of bacterium, this idea is not supported by further study. It is essentially a parasite of the red blood-cell; attempts to cultivate it on various culture mediums have been unsuccessful and the inoculation of large amounts of blood from a severe case of Oroya fever has failed to infect a monkey or rabbits.

From the present evidence it would appear that the organism which we have observed in the blood in Oroya fever belongs to a group of micro-organisms intermediate between the protozoa and the bacteria, just as perhaps the spirochetes form another such group. It resembles in its characteristics more closely those given for two species of *Grahamella N. G. Protista* described and classified by Brumpt[21] in October, 1911, although in preparations stained by Giesma's or Wright's stains the presence of reddish-stained granules and of bluish cytoplasm in many forms would favor its relationship to the protozoa. It may be preferable, however, until further information as to its nature is acquired, to follow Brumpt in his classification of *Grahamella,* and to go no further than merely to place this species for the present with the *Protista.* While up to the present we have not had the opportunity of studying the bodies in the erythrocytes of the mole described by Graham-Smith[22] and others and classified by Brumpt as parasites, it would appear from the descriptions in the literature that these bodies constitute an organism of a species closely related to the one which we have encountered in the blood in Oroya fever. As in the genus *Grahamella,* the organism of Oroya fever is characteristically rod-shaped and evidently multiplies by binary transverse division. Apparently, however, the resulting elements do not always separate at once but remain connected in chains of three, four and five. On the basis of this difference and of other additional characteristics such a motility, staining reactions and size, it appears preferable to propose provisionally for the organism studied by us the name of *Bartonia bacilliformis.* The generic name of *Bartonia* is suggested owing to the fact that Barton in 1909 stated his belief that the inclusions earlier observed in the red cells were protozoa.

The genus may be defined for the present as follows: Organisms possessing peculiar staining reactions, cytoplasm and chromatinic substance differentiated with difficulty; rounded or bacilliform in shape, sometimes occurring in chains of several segmenting organisms; reproduction by binary transverse division; endowed with independent motility; and living as parasites in the red blood-corpuscles.

As a type species the parasite of Oroya fever may be briefly described as follows:

Bartonia bacilliformis. Gen. et sp. nov. Parasites consisting of rounded or oval forms or of slender straight, curved or bent rods occurring either singly or in groups, but characteristically in chains of several segmenting organisms, sometimes swollen at one or both ends and frequently beaded. Reproduction occurs by binary division. Endowed with independent motility, moving in the direction of the long diameter, living within the red blood-corpuscles of man and producing a grave form of anemia known in Peru as Oroya fever. Stained preparations suggest differentiation of cytoplasm and nuclear material.

VERRUGA PERUVIANA

Verruga peruviana is a disease particularly characterized by an eruption on the skin and occasionally on the mucous membranes, particularly of the mouth and throat. The lesions present great variations in appearance. The distribution of the cutaneous eruption resembles somewhat that seen in yaws; but in many other respects the lesions of the disease are entirely distinct. In uncomplicated cases, neither the parasites of Oroya fever nor those of malaria are present in the blood; though as verruga peruviana is contracted in regions in which Oroya fever and malaria are common diseases among the inhabitants, and visitors are likely to contract such maladies, it is not surprising that concomitant infections with these parasites frequently occur. Indeed, according to the statistics of Peruvian physicians, in a large percentage of verruga peruviana cases the blood examinations shows an infection with malarial parasites; and in one of the twenty-two cases of verruga peruviana which we studied a concomitant infection with Oroya fever was observed.

[21] Brumpt: Bull. de la Soc. pathol. Exotique, 1911, iv, 514.

[22] Graham-Smith: Jour. Hyg., 1905, v, 453. Thompson: ibid., 1906, vi, 574. Balfour: Report Welcome Research Laboratory, 1906, ii, 1911, iv; Bull. de la Soc. path. exotique, 1911, iv, 660. Leger: ibid., 1913, vi, 247.

It is quite evident that verruga peruviana represents an entirely distinct disease, and that it is not a form of frambesia or of syphilis. In our studies both of these diseases were excluded. The disease owes its origin to a virus which produces on intratesticular inoculation into rabbits a characteristic local lesion. The incubation period varies in rabbits from ten to twenty-two days. So far fifteen rabbits have been successfully inoculated, and the virus is now in its third transplant in these animals. In dogs and monkeys, cutaneous and subcutaneous, and sometimes intraperitoneal, inoculation has given rise after from eleven to seventeen days to localized lesions, which sometimes resemble closely those observed in man. The virus is also in its third transplant in monkeys. Jadassohn and Seiffert,[23] Mayer, da Rocha-Lima and Werner[24] have also been successful in single cases of verruga peruviana in transmitting the virus to monkeys.

The Wassermann reaction was negative with one exception in the cases of verruga which we examined. Moreover, no fixation of complement could be obtained when a specific antigen was substituted for the antigen used in the routine Wassermann reaction.

The biologic examination of an extract prepared from a cutaneous nodule in a case of verruga showed the presence of a hemolysin which was active in relatively high dilutions. The properties of this hemolysin are still under investigation.

Having become convinced that Oroya fever and verruga peruviana were two entirely distinct diseases, and having secured through the kind assistance of Dr. Matto, professor of bacteriology in the University of Lima, a volunteer (a Chilean), we made a direct inoculation from two cases of verruga peruviana. A portion of a skin lesion from each of the two patients of verruga was removed, and within twenty minutes of the time of this operation the skin of the normal person over the left shoulder was thoroughly scarified, and a portion of the nodules removed from the verruga patients thoroughly rubbed into the scratches. The vaccination scratches healed entirely at the end of about ten days, and the skin appeared normal. On the sixteenth day two small groups of cherry-red papules at the end of some of the vaccination scratches appeared, and a few days later another small group became visible. These increased slowly in size until the thirty-fifth day, when two of the groups were removed. The blood examination of the vaccinated person never revealed any of the parasites observed in the blood of Aroya fever cases, and no appreciable anemia developed. No generalized eruption occurred and the person was in good health at the time of our departure from Lima. It seems hopeful that by using the virus of verruga peruviana after one or two passages through the rabbit's testicle, or possibly through several more in monkeys, a successful means of vaccination against verruga peruviana may be obtained.

UTA

Uta is a disease which has existed in Peru since prehistoric times, and the lesions of which have been supposedly depicted on the ancient huacos of the Incas. It has been stated by various authorities that the disease represented a form of syphilis, or one of prehistoric leprosy, or a special form of lupus vulgaris. In recent years two extensive monographs on the subject have appeared from Peru, one by Tamayo[25] in 1908 and the other by Palma[26] in 1909. Tamayo regarded the disease as a special form of lupus vulgaris. Palma concluded that it was a specific disease, which was not to be confounded with other South American maladies, and that it was not a form of tuberculosis. The disease was observed by Past-Assistant Surgeon Perry, United States Public Health Service, in his travels through Peru; and by Surgeon-General Blue who, in conversation with one of us prior to our departure, mentioned its occurrence among the schoolchildren of Surco, one of the Peruvian mountain towns in which the disease occurs abundantly. In both Surco and Otao (the latter town deriving its name from the prevalence of the disease there) a large proportion of the inhabitants are either afflicted with the disease, or show the disfiguring scars which have resulted from a previous attack, on the face, arms or legs. From our investigations we were able to show that uta is due to a species of Leishmania. The flagellate stage of the organism has been obtained by us, and animals have been successfully inoculated from a human case.

ACKNOWLEDGMENTS

In connection with the investigations of the commission wish to express publicly our thanks, particularly to the C poration of Harvard University for generously providing fu for the maintenance of the expedition and to the dean of Harvard Medical School and the dean of the Graduate S of Medicine for their interest and assistance in the orga tion of the expedition; to the United Fruit Company of ton for generously furnishing us with transportation New York to Colon and return; to the Royal Mail Stea Company and the Pacific Steamship Navigation Company furnishing us free transportation from Balboa to Guay and from Callao to Balboa, and to the Panama Railroad pany for courtesy in regard to handling our baggage a the Isthmus. We also wish to express particularly our g tude to Mr. J. W. Blaisdell, assistant manager of the C Railroad Company of Peru, who very generously on se occasions furnished us with special railway facilities in studies carried on between Lima and Oroya, and to Dr. B. Bailey, Cerro de Pasco Railway, for many kindnesses du our expedition from Oroya to Cerro de Pasco. To the foll ing physicians and officials we wish to express our grate acknowledgment for many kindnesses and for assisting us obtaining material in connection with our studies: Drs. Dee Perry, Caldwell, Darling and James in Panama; Dr. Park Consul General Baker and Dr. Pereja and other officials of t Board of Health in Guayaquil; to President Billinghurst Peru and to the American minister, Mr. Henry Clay Howard the introductor of ministers, Mr. Cisneros, and Drs. Odriozola Arce, Grana, Barton, Hercules and Matto in Lima. We also wish to express our great appreciation of the very valuable assistance rendered us by Dr. J. C. Tello, director of th ethnologic museum, Peru, in facilitating our obtaining material and in assisting us in making arrangements in regard to some of our investigations. Without Dr. Tello's assistance some of our investigations would probably not have been brought to so successful an issue as they were. A more detailed statement of our appreciation of the kindness shown us by a number of the above-mentioned physicians will b made in the complete report of the expedition. Finally, we wish to express our deep appreciation of the efficient services rendered by Miss Nora Dwyer, who accompanied us as secretary on the expedition.

lowed, such as some effervescing water, ginger ale, some pungent mint chewing-gum, or even a simple peppermint lozenge. Of course the value, in such conditions, of vegetable sours such as lemonade, orangeade or a piece of orange is well understood. These will increase the mouth secretions and prevent drying of the mucous membrane, which is such a frequent cause of ulceration.

Various preparations of glycerin diluted with water, with or without boric acid or borax, or boroglycerid, or milk of magnesia, are all valuable in preventing or aiding in the healing of a sore mouth.

If the tincture of iodin does not heal an ulcer or fissure, one or two applications of either the stick nitrate of silver or a 25 per cent. solution, applied by means of a swab, will generally cause healing.

If the patient is too ill for strenuous or perfect cleanliness of the mouth, as soon as convalescence is established extra care should be given the mouth and teeth.

It should not be considered that a patient has been thoroughly examined until the condition of the mouth has been investigated. As before stated, too many chronic diseases have their source and continuation from diseases of the gums or from neglected, decayed teeth, to say nothing of diseased tonsils. A fetid, bad breath should always be investigated, as it is generally due to a chronic inflammation in the mouth. While a large portion of adults over 40 have more or less pyorrhea alveolaris, a large number of these patients may have the condition entirely prevented, and by various methods to-day many patients are cured of what was long considered an incurable condition.

Riggs' disease is a disease of the bone, really an alveolitis, and if the process continues the alveolar process becomes so damaged that the teeth become loosened and are lost. This serious condition begins at the juncture of the teeth with the gums, and perhaps the most frequent cause is neglected tartar acting as an irritant and allowing inflammation to start in the gum tissue. While tartar deposits are not abnormal to most mouths, it must be removed frequently in order that the teeth and gums will not be injured. If it remains long it becomes hard, and although the irritation from it may not always cause inflammation on account of a healthy person constantly producing antitoxins of various types to ward off and combat pus infection, still such deposits are always sources of danger, and even if a well person tolerates such irritants, if he becomes ill, infection of the gums rapidly begins. If the gums become really inflamed, they naturally swell and may pout away from the teeth. This allows the mouth secretions, saliva, food and germs to become lodged deep in the pocket between the swollen gum and the teeth, and serious inflammation is the result.

The danger from infected cavities in teeth is perhaps understood by patients, and if not understood, more or less frequent attacks of severe pain causes them to seek a dentist for treatment of such conditions; but the laity does not thoroughly understand the danger from infected gums, especially as they may not be attended by pain. Consequently we must teach in schools and in families how important is hygiene of the mouth. Regular visits to the dentist are as important as any other branch of preventive medicine. Besides efficiency in their treatment, the dentists are to-day doing splendid educational work in preventing the development of pyorrhea alveolaris.

Prevention of the disease means at least twice daily brushing of the teeth carefully with a brush stiff enough to remove the first soft deposits of tartar and to remove particles of food that remain on or between the teeth. The particular tooth-paste or powder selected depends on the individual choice. It should not be too soapy to prevent removal of soft tartar deposits. It should not be harsh enough to injure the enamel.

Recent investigations by Gies[1] of Columbia seem destined to revolutionize our belief in regard to what sort of substances are best to use in cleaning and preserving the teeth. He emphasizes the fact that the direct factor in decay of the teeth is acid, and this acid is believed to be lactic. Mucin films depositing on the teeth may retain this acid or acid-yielding material and thus continue the acid irritation, and this acid later "dissolves the calcium and other inorganic matter from the enamel," and later penetration of the dentin occurs. Of course during this process micro-organisms develop more or less and add to the local disturbance.

Gies has found that so-called antiseptic mouth-washes and alkaline washes do not wash off or dissolve this adherent mucin, and therefore are not effective in preventing decay of the teeth. He quotes Pickerill[2] and a discussion in the New York Academy of Medicine[3] and Dr. Howe[4] and records his own investigations to show that the vegetable acids, such as diluted vinegar and the fruit juices and their acids, are the most successful cleansing substances that can be used on the teeth. These investigators all state that a diluted vinegar is perfectly successful as a cleanser of the teeth. They also believe that starches and sugars should never be eaten alone, but should be certainly followed by some acid substance, as some of the acid fruits or some of the vegetable sours. After most meals, therefore, it is good sense to eat a little fruit, and on going to bed perhaps the most successful cleanser of the teeth is a little sour fruit or diluted fruit vinegar.

Children and patients should also be taught to brush the gums as well as the teeth, and when it is needed a patient should be taught to massage the gums. The use of wooden toothpicks to remove particles between the teeth that cannot be removed by the tooth-brush should be approved.

Many patients' teeth are so close together that particles of food remain lodged between them and cannot be removed in any other way. Dental floss should certainly be used occasionally, or frequently, if possible. If inflammation actually occurs in the gums or around a tooth, the advice and care of a dentist are needed.

When mouth-washes and the proper use of iodin by the dentist do not cure a pyorrhea, some success has been obtained from the use of autogenous vaccines.

Germs may be swallowed into the stomach, where they are more or less constantly killed, but they may not always be killed, and they may pass to the intestine and there grow and be absorbed or cause some local inflammation, such as appendicitis.

Another frequent source of danger from such mouth germs is absorption into the lymph-vessels. They may thus be a cause for enlarged cervical lymph-nodes which attempt to arrest the spread of the infection. These lymph-nodes may not only get into serious trouble themselves, but may sooner or later allow the poison or germs to be absorbed into the blood, and then systemic infection begins.

A NEW INDICATOR OF PATHOLOGIC TISSUE CHANGES

In the modern investigation of neoplasms which is being pursued so vigorously it has been of fundamental importance to ascertain the specific peculiarities of the abnormal tissues. When once it is made clear precisely wherein pathologic growths differ from the normal tissues which they accompany or supplant, and what are the stimuli which initiate and promote their development, a great step in advance will have been taken. So far as the morphologic features are concerned much valuble information has long been at hand; but after all, structural anomalies are merely the formal expression of alterations due to physical or chemical changes either within the cells themselves or in their immediate environment. The solution of the underlying problems of the development of neoplasms is closely bound up with the knowledge of the inciting causes. The possibility of an artificial inhibition or retrogression of such growths is likely to rest on similar information.

Actual chemical analysis of neoplasms has as yet thrown little light on their individuality. When biologists first pointed out how sensitive living cells are to slight alterations in their environment, how readily they respond in most diverse ways to changes in the proportions of the inorganic elements, for example, which bathe the protoplasm, hopes ran high for rapid progress in the study of tumor growth. But blood and lymph and tissue juices exhibit extreme intricacies of composition in almost endless details. The make-up of these body fluids is continually undergoing changes which represent themselves in new equilibria of reaction so that it is almost as difficult to postulate from moment to moment what is the normal of such complex mixtures as it is to detect the deviations therefrom. If, indeed, the difficulties of exact estimation of the inorganic components of the tissues are considerable, the detection of foreign organic compounds such as may represent products of pathologic change is incomparably more difficult. Nor is the situation made easier by the fact that profound biologic change is often inaugurated by extremely slight chemical provocation. The phenomena of anaphylaxis, which seem almost to baffle chemical skill in their interpretation owing to the minute quantities of actual reagent substances involved, bear witness to this fact.

Whenever the investigation of a scientific problem reaches a complexity which taxes the resources of current methods the advent of new or improved modes of diagnosis and of novel indices of altered conditions are welcomed. In this spirit we refer to the unique yet simple biologic method which Professors Underhill and Woodruff of Yale University have adopted to demonstrate pathologic changes that may arise as the result of chemical disturbances.[1] Arguing that the complications which are involved in employing the complexly organized higher animals as test subjects for the detection of abnormalities in tissue extracts, etc., are considerably diminished when the organism is reduced to the lowest terms, the single cell, they have introduced the unicellular animal, paramecium, as an indicator of pathologic alterations in tissues. The justification for this is based on the fact that in "pedigreed" races of this protozoan the rate of reproduction is a most accurate indication of the chemical composition and temperature of the environment, as remarkably slight variations in the culture medium produce characteristic responses by the animals. Indeed, the rate of reproduction may be said to be a function of the environment of the cell.[2]

The plan of the Yale investigators was essentially to compare the rate of reproduction of suitable subcultures of paramecium bred on extracts of comparable normal and pathologically altered tissues or organs. Such a procedure is obviously not without pitfalls, and calls for an abundance of well controlled statistics. It is not without interest to note incidentally that the particular "biologic reagent" employed in this instance was the pedigreed race of *Paramecium aurelia* which Professor Woodruff has had under daily observation for more than six years and through more than 3,700 generations.[3] To test the efficiency and limitations of the protozoan protoplasm as an indicator of pathologic change, preliminary investigations were conducted with normal and nephritic kidneys. These were satisfactory in that they failed to indicate changes due to purely physiologic or anatomic circumstances. Thus there was no essential difference in the division rate of paramecium when subjected to the influence of extracts prepared from the separate kidneys of one animal or from kidneys of different individuals. Extracts made from the kidney of a starving animal behave in a manner identical with those from a well-fed one. On the other hand, the division rate is markedly depressed by the renal extracts of individuals with tartrate nephritis, with every evidence that the pathologic change in the kidney tissue itself (rather than tartrate accumulated in the organ) is responsible for the action observed on paramecium.

---

[2] Woodruff, L. L.: Biochem. Bull., 1912, i. 396; Woodruff, L. L., and Bunzel, H. H.: Amer. Jour. Physiol., 1909, xxv, 190; Woodruff, L. L., and Baitsell, G. A., ibid., 1911, xxix, 147.

[3] See Woodruff, L. L.: Biologisches Centralbl., 1913, xxxiii, 31.

Although there is reason to suspect that in carcinoma abnormal products may arise through the local development of the neoplasm and then exert a remote detrimental effect on the organism as a whole, there has been little compelling evidence for this assumption. Underhill and Woodruff have applied their protozoan test method in the study of primary carcinoma of the human breast as a characteristic type of abnormal growth. In so far as one may judge from the observations on a limited number of cases, extracts of such neoplasms, in certain concentrations, show a very pronounced depressant influence on the division rate of paramecium when compared to that obtained with the same protozoan race bred in normal mammary tissue extract. In some instances the depressant influence may be so profound as to lead to the death of the paramecia within two or three days. Underhill and Woodruff are convinced that the differences in concentration which may exist between the normal and abnormal breast tissue extracts cannot be held responsible for the detrimental action of the abnormal extracts on paramecium; for when the concentrations of the two extracts under discussion are made as nearly equal as possible the depressant phenomena still appear in the carcinoma extracts.

It is too early to theorize at length on the possible significance of such striking results. They may, of course, be due to the absence or to a deficiency in the solutions of substances essential for the life processes of paramecium, or to the presence of substances inimical to protoplasm. If the latter hypothesis is correct, it is possible, as the investigators themselves point out, in view of the probable greater concentration of these substances in the neoplasm, that their absorption may contribute to the production of the symptoms characteristic of the development of cancerous growths in man. An efficient new method of study is almost always likely to yield a rich harvest of applicable facts. The present interesting findings encourage us to look forward to additional contributions along these promising lines in the widely cultivated field of cancer research.

ANOMALIES OF SUICIDE

Speculation has been concerning itself with the motives in the minds of those unfortunates who find it necessary to end their earthly sorrows in some violent manner. How important a feature this is in the total mortality list is shown by the fact that about fifteen thousand lives a year are lost in the United States by this route. The suicide-rate for 1912, according to Hoffman,[1] for the hundred largest cities of the country, comprising a total population of 23,336,000, is somewhat less in 1912 than in 1910 and 1911, and considerably less than the rate in 1909 and 1908, which chronicled a much larger number of suicides than usual, probably because of business troubles consequent on the panic of 1907.

One thing clear about suicide statistics is that their number has been in direct ratio to the number of business failures. While the 1912 suicide-rate is somewhat consoling, the five-year rate as compared with each five years for the last twenty years shows how much suicides are increasing. The average suicide-rate for the five years from 1908 to 1912 was 20.2 per hundred thousand of population; for the five-year period from 1893 to 1897 it was 15.7. If any of the contagious diseases had a mortality-rate nearly one-third higher now than it had twenty-years ago, we should be much discouraged unless there was some promising method of prophylaxis in view.

Suicides are not most frequent in those parts of the country in which one would naturally expect them to be. Usually suffering is considered the most important factor in leading to suicide and therefore it would be expected that the cities with the largest variations of temperature, especially those subject to the extremes of heat and cold, would present the highest suicide mortality. *Almost exactly the opposite is true.* The three cities that head the list are in California—San Francisco with a suicide-rate of 50 per hundred thousand of population, San Diego with more than 40, and Sacramento with 37. Then comes Hoboken, N. J., with 34, followed by Los Angeles with 32 and Oakland, Cal., with 31, St. Louis coming in between the last-named two. All of the cities of California, then, have a high suicide-rate. Hoboken's rate is doubtless so high, partly because of its large Teutonic population, but much more because a number of those who contemplate suicide in the great city near it go across the Hudson River in the hope of escaping identification or at least avoiding the publicity likely to come in New York.

The cities of the country having the lowest suicide-rate are in the oldest-settled portions, especially in the South and in New England. In the last twenty of the hundred cities Massachusetts has eleven towns with a suicide-rate of 10 or less per hundred thousand. Augusta, Ga., has the lowest rate, 3.7, and the fourth from the end of the list is Charleston, S. C. Williamsport, Pa., has the unique distinction of having had no suicide during 1912, and during the preceding decade the rate was only about 9 per hundred thousand, or less than one half the average for the hundred American cities at large. Exceptionally low rates prevailed for the decade in Elmira and Newburgh, N. Y., Orange, N. J., Savannah, Ga., and Johnstown, Pa. Indeed, their rates are so low that Mr. Hoffman suggests a doubt as to the absolute accuracy of the returns, for there is more or less of a tendency to classify suicides as accidents in the absence of a precise coroner's verdict to the contrary. The cities of the West and middle West have as a rule a much higher suicide-rate than those of the East and South. Springfield, Ill., is seventh on the list, while the first Eastern city is McKeesport, Pa., which with its large foreign population is sixteenth on the list. Chicago is twenty-first with a suicide-rate of 22.2 for the decade, while New York with its very mixed population has the same average as the whole country for the decade, 20.2. Atlantic City, N. J., is in the same class.

---

[1] Hoffman, Frederick: The Spectator, Oct. 2, 1913.

Suicides also occur most frequently at an unexpected time of year. It is not on damp, dark days which would naturally add to the depression of those who already have dark thoughts and consequently lead to suicide, but in the month of June that most suicides are recorded. It has been shown over and over again by the comparison of suicide records of cities with reports of their weather bureaus that suicides were considerably more frequent on bright, sunny days than in dark, cloudy weather. December has the lowest suicide-rate of the year. It is psychic, not physical, depression that tempts to suicide. The moment at which there is a deep feeling of the contrast between their own unhappiness and what they imagine, at least, to be the happiness of others, is the time chosen by the discouraged to end it all and get away from what to them is unbearable.

The highest suicide-rate is not found among the very poor, but among the well-to-do. Very few suicides are absolutely without resources. Even those who have failed in business are often not among the absolutely ruined, but among those who have lost a considerable amount of money, yet retain ample to begin life on a more moderate scale or to enable them to take up their business once more and make a success of it. They are as a rule much better off than when they began their business career. Many of them carry insurance and have kept up payments on it; hence the interest of life-insurance companies in the subject.

Insurance companies would gladly assist in any movement that would bring about a lessening of the loss of life from suicide by which a needless and heavy burden is placed on life-insurance policy-holders through the enforced payment of claims often long before the attainment of normal expectation. Mr. Hoffman points out how much economic and social dependence with serious consequences to the taxpayers of the several states must result from these self-murders, and he suggests that "in an age which concerns itself so generally with the problem of the conservation of natural and human resources it would seem that the time has come for a more intelligent public interest in what is, without question, one of the greatest moral and social problems of the time."

re[illegible] should take more interest in these problems. So

NUTRITION IN PARIS

Whenever the cost of living increases we are at once brought back to the ever-recurring question as to the ideal ration for man. Communities and even nations, like families, become accustomed or adjusted, as it were, to certain modes of living, in which are included their dietary habits and choice of foods. To speak of nutrition in certain countries without mention of rice would appear quite as extreme as to plan a dietary in the United States without the inclusion of bread of some sort. Such national food habits are doubtless dictated at the start by economic and agricultural considerations. Even within small circumscribed geographic areas the eccentricities of diet customs are exemplified in striking ways. The differences between the range and derivation of the menus of an ultra-fashionable restaurant and the bill-of-fare of the modest "dairy lunch"—the preponderance of high-priced cuts of meat and animal foods with relatively few examples of pastry dishes in the one, and the evident popularity of lactovegetarian meals in the other—make one wonder whether there are, after all, any fundamental dietary laws that can be laid down for people in general. We can scarcely assume that large groups of the population would voluntarily subsist for any length of time on dietaries which were manifestly inadequate for their nutrition. Yet here are the striking contrasts side by side in the routine observation of small and large communities alike.

Physiologists have propounded certain dicta regarding the nutritive needs of man and expressed them both in terms of familiar nutrients and in units of energy, calories. How these have been arrived at need not concern us seriously here. In part it has been by direct feeding experiment to ascertain the limits at which permanent gains or losses to the bodily economy result, and in part by statistical methods whereby the actual food consumption of individuals and groups has been noted and the averages thus gained taken as an index to the probable needs of the human organism. On the whole, the agreement of these two methods, the experimental and the statistical, has been surprisingly close. Recently we discussed some of the limitations to which the free choice of a dietary may be subjected by extraneous circumstances.[1] The collection of suitable statistics throughout the world cannot fail to add useful information as a basis for larger dietary programs, precisely as the study of special groups (laborers, poorer classes, prisoners, etc.), has indicated limitations that need to be recognized by authorities who deal with public problems of nutrition.

The French bear the reputation of being a well-nourished or at least a well-fed nation. This is sustained by the data collected by Gautier,[2] one of the French experts in the field of nutrition study. His figures have an exceptional value and added interest because they represent the findings not of a single day or week, but of no less than two decades. The statistics are those of food consumption on the part of the great majority of the inhabitants of Paris—the "average" inhabitants—derived from public records of taxes paid on foodstuffs and from actual investigation among peasant or "bourgeois" families. In consideration of the long period over which the records apply and the large numbers of people involved—nearly three millions—the discrepancies between rich and poor, undernourished and overfed, are probably in good part equalized. Here are the figures, expressed as a daily average: obtained from vegetable sources: bread, 420 gm.; green vegetables, 250; cereals, 40; potatoes, 100; sugar, 40; fresh fruits, 70; alcoholic beverages, 432; from animal sources: meats, 200 gm.; eggs, 24; cheese, 8; butter and oil, 28; milk, 213; to which may be added salt, 20 gm., and water, 950. When these are translated into terms of the familiar nutrients they furnish a daily total of proteins, 97 gm.; fats, 58 and carbohydrates, 418, with an energy value of over 2,500 calories. This accords well with established "standards" for the average man. Incidentally national characteristics are emphasized in the relative proportions of foods consumed as, for example, the liberal use of bread. Despite such incidental variations, the actual nutrient intake of peoples seems to be much the same the world over.

---

THE RAILWAY TRESPASSER

So much does the spectacular attract the public mind that the killing of a dozen people in a single railway accident calls forth throughout the country newspaper extras, the first page flaring with headlines. Yet, states Mr. Dow,[1] the general safety agent of the New York Central lines, more than that number of persons, fourteen daily on an average, have been killed while trespassing on railway property; and for every one thus killed another has been injured, in general seriously—maimed or crippled for life. Nor are all such persons tramps, negligible derelicts, who would not have been crushed to death under the railroad cars had they been about some worthy business. Only 25 per cent. of railway trespassers are tramps. According to Interstate Commerce Commissioner C. C. McChord,[2] the casualties, taking under consideration a period of twenty years, were suffered by: 25,000 young people (victims of their elders' neglect), all under 18, many under 10—children playing behind or "hitching" on cars or picking coal from the tracks; 36,276 of the sometimes unjustly berated tramps; 120,103 citizens, men and women, mostly wage-earners going to and from work, heads of families, people whose homes were in the vicinity. The total number of railway employees and passengers killed each year is less than the total number of railway trespassers killed.

Apart from their tragic connotation with death and suffering, Dow rightly asserts that such figures illustrate accurately the great economic loss suffered by the country through the negligence of our sanitarians, educators, legislators and humanitarians, who, in their laudable effort to prevent disease, to promote the observance of health laws and the study of eugenics, have side-tracked, so to speak, the issue of railway trespass.

There are two chief remedies advanced by Dow for the evil of the unlawful track-walker—education and legislation. He would have public-school children taught a careful, systematic and definite plan of safety—a plan to be graphically presented, which should be extended to every industrial concern situated near a railway—because such workers furnish by far the most trespassers and victims. As to legislation, there are statutes at present in some states which make trespassing on railway property a misdemeanor and punishable by a fine or a jail sentence; but there is no uniformity in the laws and, indeed, even where such laws exist, it is difficult to obtain the conviction of a trespasser. Many people find humane motives in a railway corporation hard to believe in; certainly, however, the presentment of Mr. Dow, a railway company representative, has this wholesome flavor. His company gains nothing thereby. Such a corporation is not liable when a trespasser is hurt or killed; nor are the tracks injured by any one walking on them. The engineer, also, whose heart is as human as another's, should be considered, for it is his paramount duty to concentrate his attention on his work and to protect from disaster the passengers in his care. One may well sympathize with him whose engine had struck and fatally injured a track-walker: "there were tears in his eyes and his hand trembled as he nervously passed it over his forehead in a gesture of despair and said, 'Such things get my nerve. I wouldn't kill a dog if I could help it; and there is hardly a day when my heart is not in my mouth a dozen times on account of people walking the tracks where I run, barely escaping getting caught by me.' "[3]

Current Comment

MORE FRIEDMANN "CURE" ADVERTISING

In the New York *Sun* for October 26 appeared a brief news item in the form of a cable dispatch from Berlin. It was to the effect that Professor Frederick Kraus, a Berlin internist, had expressed a favorable opinion regarding the use of the Friedmann serum in surgical cases. A few days after this notice appeared, mimeographed copies of the newspaper article were sent broadcast over the country by the Standard Distributing Company, Room 506, 90 West St., New York City. This address, even to the number of the room, is that from which the "Friedmann Institute of New York, Inc.," was doing business a few weeks ago. The cable dispatch and the way in which it is being used but further emphasize the wretchedly commercial spirit that actuates this whole miserable Friedmann business. To the careless reader, and especially to the reader of headlines, the newspaper article gives the impression that the Friedmann "cure" has been proved of value in consumption. As a matter of fact no such statement is made. But relying on the inevitable carelessness of the common reader and the notorious optimism of the consumptive, this report is scattered broadcast as another move in the Friedmann advertising campaign. What though the tuberculous be tortured once more with false hope—what is another turn of the rack—when dollars are at stake?

SOME FEATURES OF STAINING TECHNIC

In some of their most important practical operations the bacteriologist and the histologist have long since adopted technical methods which are largely based on a sort of refined empiricism. Culture mediums are made up according to approved formulae of which the rationale would be difficult to define; and the microscopic worker employs an outfit of selected stains which somehow furnish differential results despite the ignorance which attends their uses and reactions. It is almost needless to say that none of these practices will rest on firm foundations until the principles underlying their application are unearthed, examined and clearly understood. The rapid progress of biochemical research is already leading to a better appreciation of what some of the long-accepted phenomena really mean. An illuminating instance may be cited in the case of micro-organisms. The group of acid-fast bacteria derive this designation from their peculiar behavior to dyes. They can as a rule be stained with aqueous solutions of anilin colors only with great difficulty. As is well known, Robert Koch succeeded in his demonstration of the tubercle bacilli because of the unique tinctorial responses of the latter in tissue sections. Ehrlich found that tubercle bacilli which were stained with anilin dyes dissolved in anilin water were not decolorized by treatment with strong acid. This fact occasioned the introduction of the expression "acid-fast." Ehrlich and others assumed that the resistance to color removal by acids is due to the presence of difficultly permeable capsules or membranes in those organisms which manifest the acid-fast properties. Still other investigators, however, have expressed the conviction that the special tinctorial features of the acid-fast group are attributable not to the impervious nature of the cell-structure but to unique chemical compounds having specific affinities for certain dyes. The dominance of the latter viewpoint is now assured by the studies of Tamura.[1] These show that not only the acid-fast and alkali-fast properties of two typical organisms, *Bacillus tuberculosis* and *Mykobacterium lacticola perrugosum,* but also their positive behavior to the Gram stain, are due to the presence of an alcohol, mykol, in their cells. This substance has a comparatively high molecular weight with an indicated formula $C_{29}H_{56}O$, and is doubtless in part present in the bacterial body as an ester of some higher fatty acid. The chemical features here recited remind one at once of the higher alcohol cholesterol which also plays an important rôle in connection with many types of both animal and plant cells. It is precisely such information as this just published from the laboratories of Profs. A. and H. Kossel at Heidelberg that promises to take the practice of bacteriologic technic out of the domain of laboratory magic and put it on a secure scientific footing.

RED NOT A SATISFACTORY DANGER-SIGNAL

Red has been the sign of danger and a warning signal since the earliest times. Just why it was selected as a danger-warning is a question for the anthropologist and historian to determine. It is unfortunate that this color, which is becoming increasingly important with the growing danger of accidents in civilized life, is the color to which many human eyes are insensitive. Color-blindness is apparently becoming more common. In its most frequent form, it is impossible for the color-blind person to distinguish red from green, yet those two colors, which are the most confusing to the human retina, are the very ones which are in most common use as signals for danger and caution. So common is red and green color-blindness that all licensed pilots, masters of vessels, engineers, firemen, motormen and others employed in directing vessels, trains, trolley-cars and other means of transportation are required to submit to a color-test and to prove that they possess an accurate degree of red-green color perception. The simple expedient of selecting as a sign of danger a color to which practically all human eyes are susceptible has only recently been suggested. *Drugs, Oils and Paints,* in a recent issue, contains an article by Dr. Francis D. Patterson, suggesting a new signal to take the place of the familiar red warning. Patterson calls attention to the fact that the number of industrial accidents is at present enormous and is apparently increasing. As approximately one male in every twenty-five has a deficient color perception and as most of these have an impaired sensibility for red, Dr. Patterson argues that the retention of this color as a danger-signal is simply inviting further increase in accidents. His objection is based on the fact that many persons are color-blind to red and are consequently not only barred from any occupation in which a color perception is necessary, but are also deprived of the protection from accidents and danger supposed to be offered by danger-signals. He also objects to red for practical reasons; it is a fugitive color, difficult to distinguish, fading on exposure to sunlight and requiring frequent repainting. The possibility that red and green color-blindness will increase rather than diminish in the future only serves to emphasize the unfitness of these colors as signs of danger and caution. Experiments with the spectrum and with color-blind persons, as well as with various colors at different distances, leads Patterson to the conclusion that yellow and blue are the best colors for danger signals, as he says that they are the only colors which give rise to a normal color-sensation as soon as they become visible, are the most luminous colors of the spectrum, and are permanent and fast, while color-blind persons react normally to them. It has long since passed into a proverb that it is easier to change the laws of the people than to change their customs. The fact that many persons are unable to distinguish red from other colors should alone be sufficient to cause it to be discarded as a danger signal. Whatever color is adopted should be selected after the most careful physiologic and optical investigation.

PENNYROYAL, TANSY AND OTHER "EMMENAGOGUE" OILS

Because of its inherent interest to many physicians who still assume that a number of oils, including products like pennyroyal, are efficient emmenagogues and abortifacients, we recur to the subject on the occasion of additional evidence now available.[1] Some of these drugs are still official in the United States, the British and other pharmacopeias. Macht has now reported the added details of his study of the effect of these substances on the isolated uterus. The following oils were examined: oleum hedomae (pennyroyal), oleum sabinae (savine), oleum tanaceti (tansy), oleum rutae (rue), oleum thymi (thyme), oleum terebinthinae (turpentine) and apiol. They have no specific or directly stimulating action whatever on the uterine muscle; on the contrary, they inhibit the contractions of the uterus and even paralyze it. It ought to be clear then, once for all, that if these oils exhibit any "emmenagogue" or abortifacient phenomena whatever in the organism it is due to a general constitutional poisoning or gastro-intestinal irritation and not to any specific action in accord with the intent with which they are sometimes administered.

CARELESSNESS AND DIPHTHERIA

The office of the Georgia State Board of Health at Atlanta was recently compelled to close by an epidemic of diphtheria among the officers and employees. Ten persons were affected. Only the secretary and one other physician escaped the disease. The secretary of the board is reported to have said that the disease was contracted from specimens which were so carelessly prepared by the physicians who sent them in that no indication was given of what the packages contained. Ordinary envelopes, it is said, were sent in containing portions of membrane placed between pieces of cardboard or paper; other envelopes contained cotton swabs which fell out when the package was opened. Even if this were not a violation of the postal laws, it is almost inconceivable that physicians could be so careless as to send in this manner material as deadly as dynamite or an infernal machine. It not only constituted a danger to the persons in the office of the health board, as the sequel proved, but it was also a menace to every one handling the mail *en route*. The responsibility of physicians in handling such material is great and the utmost precaution should be observed.

HEALTH TOPICS FOR WOMEN'S CLUBS

The influence of women's clubs on public health questions has been steadily increasing. Now that they have covered the field in a general way, there arises a demand in women's organizations for more accurate knowledge on the important problems of public health. Recognizing that the state board of health exists for the purpose of serving the people of its state in every way possible, the secretary of the Kansas State Board of Health has prepared an outline for the use of women's clubs in studying health questions. This outline, issued in a small leaflet, will prove of immense value in directing the work of the women's clubs desiring to take up this line of activity. Under foods and drugs appears a study of foods, including their preparation and preservation, a discussion of a proper ration and selection of foods, food adulteration, the sanitation of food supplies, drug adulteration and drug addiction. Rural sanitation, school sanitation and hygiene, the cost of preventable disease, the disposal of waste and the conditions for a pure water-supply are some of the topics included in the outline. Reference to bulletins, government publications, journals and books are also included. In directing the attention of women's clubs to these topics and in furnishing them a logical outline of work to be followed, the Kansas State Board of Health is not only doing a great service to the people of its state, but is also building up an educated following which will greatly improve the effectiveness of the work of the board itself.

Medical News

ALABAMA

Personal.—Dr. W. M. Faulk, Tuscaloosa, has been elected treasurer, and Dr. J. L. Williamson has been reelected a member of the Board of Trustees of the Alabama Bryce Hospital, Tuscaloosa.——Dr. C. L. Guice has been elected president of the Gadsden Chamber of Commerce.——Dr. R. F. Elrod, Cottonton, is under treatment in a hospital in Montgomery on account of injuries received in a mowing machine accident.——Dr. D. F. Talley has been made medical director of the Sun Life Insurance Company of America, Birmingham.——Dr. R. D. Jackson, Birmingham, fell in front of his home recently, fracturing his hip.

New Officers.—Jefferson County Surgical and Gynecological Society, at Birmingham, October 25: president, Dr. E. P. Hogan, and secretary, Dr. E. P. Solomon, both of Birmingham.——Russell County Medical Society, at Hurtsboro, October 21: president, Dr. W. B. Hendrick, Hurtsboro; secretary-treasurer, Dr. R. C. Williams, Ratchehubbee; county health officer, Dr. R. B. McCann, Seale.——Marion County Medical Society in Hamilton, October 8: county health officer, Dr. R. L. Hill, Winfield.——Baldwin County Medical Society, at Bay Minette, October 8: president, Dr. C. L. Mershon, Fairhope; vice-president, Dr. W. N. Moore, Daphne.

CALIFORNIA

New Officers.—San Bernardino County Medical Association at Redlands, October 14: president, Dr. B. F. Church, and secretary, Dr. C. G. Hilliard, both of Redlands.

State Board Election.—The initial meeting of the State Board of Medical Examiners was held in Sacramento, October 14. W. W. Vanderburgh, San Francisco, was elected president; Dr. Fred F. Gundrum, Sacramento, vice-president; Dr. Charles B. Pinkham, San Francisco, secretary, and Dr. H. E. Alderson, San Francisco, treasurer.

Personal.—Dr. C. A. Wright, formerly police surgeon of Los Angeles, was seriously injured October 20, when his wheel chair was struck by a street car.——Dr. J. M. G. Carter, Los Angeles, fell recently, fracturing several ribs.——A luncheon was given by the Associated Charities of San Francisco October 30, in honor of Dr. William Palmer Lucas, physician-in-chief of the children's department of the University of California Hospital. Dr. Robert Langley Porter of Stanford University delivered the address of welcome.

Hospital News.—The contract has been awarded for the construction of a four-story and basement, reinforced concrete hospital building at Eighth and Cedar streets, San Diego, to cost $250,000.——A tract of 305 acres near Norwalk has been purchased as a site for the new State Hospital for the Insane, to be erected in Southern California, for which $140,000 was appropriated by the last legislature in addition to the funds necessary for the purchase of the site.——The directors of the Fullerton Hospital have voted to increase the capital stock of the institution from $10,000 to $50,000.

[1] Macht, David I.: The Action of So-Called Emmenagogue Oils on the Isolated Uterus, THE JOURNAL A. M. A., July 12, 1913, p. 105; The Action of So-Called Emmenagogue Oils on the Isolated Uterine Strip, Jour. Exper. Pharmacol., 1913, iv, 547.

COLORADO

New Officers.—Eastern Colorado Medical Association at Ray, October 20: president, Dr. E. A. Clarke, Akron, and secretary-treasurer, Dr. E. D. McGill, Wray. The next meeting will be held in Akron.

Personal.—Dr. Eleanor Lawney, Denver, has gone to California for the winter.——Dr. Elsie Seelye Pratt, Denver, has been appointed a member of the Health Service Bureau of the University of Michigan.——Dr. E. W. Emery, Denver, was overcome by gas in his garage, October 1.——Dr. G. P. Lingenfelter, Denver, has been appointed a member of the visiting staff of the Denver County Hospital.

DELAWARE

Hospital News.—At a meeting of the Physicians and Surgeons' Hospital Association, Wilmington, October 22, it was announced that the present hospital site had been purchased from the Helen Bowe estate for $11,000. Dr. J. P. Pyle is president, Dr. Benjamin R. V. Beasey, vice-president; Dr. B. Allen Jenkins, secretary, and Dr. Smith Cooper, treasurer of the association.

State Society Meeting.—The one hundred and twenty-fourth annual meeting of the Delaware State Medical Society was held in Dover. October 14 and 15, under the presidency of Dr. L. A. H. Bishop, Dover. The following officers were elected: president, Dr. William P. Orr, Lewes; vice-presidents, Drs. T. H. Davis, Farnhunt, and William Marshall, Milford; secretary, Dr. G. W. K. Forrest, Wilmington (reelected); treasurer, S. C. Rumford, Wilmington (reelected); councilor, Dr. James H. Wilson, Dover; delegate to the American Medical Association, Dr. H. W. Briggs, Wilmington, and trustee of the state medical journal, Dr. George W. Marshall, Milford. The following names were submitted to the governor from which to select members of the Medical Examining Board: Drs. H. W. Briggs, Wilmington; John Ball, HocKessin; George W. Marshall, Milford; Roland G. Paynter, Georgetown; Robert Ellegwood, Delmar; W. H. Kraemer, Wilmington; P. S. Downs, Dover; E. S. Dwight, Smyrna; James Beebe, Lewes, and Joseph W. Bastian, Wilmington.

ILLINOIS

New Officers.—Knox County Medical Society at Galesburg, October 23: president, Dr. Albert C. Keener, Altona; secretary-treasurer, Dr. George S. Bower, Galesburg.

Addition to Sanitarium.—The new addition to the Prince Sanitarium, Springfield, will be occupied by Drs. Frank P. Norbury and Charles L. Patton. The first floor will be used for offices and the second floor and basement for sanitarium purposes.

State Board Meeting.—At the first meeting of the new Illinois State Board of Health held in Chicago, November 3, it was announced that the policies of the late board as regards prosecution of violators of the medical practice acts of Illinois and the enforcement of the laws of sanitation, will be continued by the new board. Dr. George W. Webster, Chicago, was continued as president of the board.

Personal.—Dr. William A. Young, Springfield, who has been ill for several months, is reported to be convalescent.——Dr. and Mrs. Malcolm C. Roe, Chana, celebrated their fiftieth wedding anniversary, October 21.——Dr. Charles A. Wilcox, Amboy, who underwent operation in a hospital in Dixon recently, has returned home, recovered.——Dr. Oscar B. Ormsby, Murphysboro, has gone to Rochester, Minn., for a surgical operation. ——The home of Dr. Horace H. Sheets, Oregon, was seriously damaged by fire October 25.——Drs. Carl E. Black, Elmer L. Crouch and George H. Stacy have moved their offices to the Ayers Bank Building, Jacksonville.——Dr. Louis B. Jolley of North Chicago fractured his arm while cranking his automobile recently.

Chicago

Roentgen Society Organized.—The Chicago Roentgen Society was organized October 24. Dr. Hollis E. Potter was elected president and Dr. James T. Case, secretary.

Swift's Surgeons to Meet.—The plant surgeons of Swift & Co. will meet in convention in Chicago, November 11 to 13, at the general offices of Swift & Co., Union Stockyards. Papers will be read covering general surgical and medical subjects, one of the most notable of which will be on "The Importance of Detecting Infectious and Contagious Diseases, Particularly Tuberculosis, Among Employees."

Examination Postponed.—The civil-service examination for attending dispensary physicians in the dispensary department of the Chicago Municipal Tuberculosis Sanatorium, originally scheduled for Oct. 28, 1913, has been postponed to Nov. 24, 1913. The examination is open to all physicians residing in Chicago. Particulars may be obtained from the secretary of the Civil Service Commission, Room 610, City Hall, Chicago.

Gynecologists Hold Meeting.—At the annual meeting of the Chicago Gynecological Society, October 17, the address of the evening was delivered by Mr. Leonard A. Busby, president of the Chicago City Railway Co., and the following officers were elected: president, Dr. Frank W. Lynch; vice-president, Dr. Henry F. Lewis; secretary, Dr. Robert T. Gillmore; treasurer, Dr. Charles B. Reed; editor, Dr. W. A. Newman, and pathologist, Dr. Arthur H. Curtis.

Personal.—Dr. Robert Sonnenschein has returned from Europe.——Dr. Otto L. Schmidt has been reappointed a trustee of the Illinois State Historical Library.——Dr. A. Arkin, formerly a member of the staff of the Otho S. A. Sprague Institute for Medical Research, and of the Department of Pathology in the University of Chicago, has been appointed professor of pathology and bacteriology in the Medical School of West Virginia University, Morgantown.

Sanatorium Corner-Stone Laid.—The corner-stone of the Sanatorium for Advanced Cases of Tuberculosis, an institution under the patronage of the Jewish Consumptive Relief Society, was laid October 19. The building, which is under construction at North Fiftieth and Belmont Avenues, will cost $50,000 and is intended as a place of treatment for patients in advanced stages of the disease, who on this account would not be admitted to other tuberculosis sanatoriums. Dr. Theodore B. Sachs will be in charge of the institution.

Public Safety Commission Organized.—The Public Safety Commission of Chicago and Cook County, which was organized recently, has appointed committees containing the following physicians: Industrial Accidents—Dr. A. M. Harvey; Electric Railway Accidents—Dr. Harold N. Moyer; Educational—Drs. W. E. Buehler and A. M. Harvey; Criminal Operations—Drs. E. R. LeCount, chairman; Harold N. Moyer, C. W. Hopkins and W. E. Buehler; Drowning, Homicides, Suicides—Dr. W. E. Buehler, chairman, and Drs. E. R. LeCount, Harold N. Moyer and C. W. Hopkins.

Clinical Congress of Surgeons.—The clinical congress of surgeons of North America will be held in Chicago, November 10 to 15. Dr. E. Wyllys Andrews is chairman of the committee of arrangements. In addition to the clinical demonstrations, whose name is legion, which are to be held in the various hospitals of the city, there will be eight evening sessions at which papers will be read and discussed. The opening meeting will be held November 10, in Orchestra Hall, at which Dr. Edward Martin, Philadelphia, the retiring president, will deliver an address. The president, Dr. George E. Brewer, New York City, will be inaugurated, and will deliver the presidential address, and Drs. Harvey Cushing, Boston, and John B. Murphy, Chicago, will read papers. On November 11, in Orchestra Hall, Sir W. Arbuthnot Lane, London; Mr. Herbert J. Paterson, F.R.C.S., London; Dr. Carl Beck, Chicago; Dr. John B. Deaver, Philadelphia, and Dr. A. J. Ochsner, Chicago, will present papers. The meeting November 12 will be held in the Gold Room of the Congress Hotel. At this time Prot. Dr. Kroenig of Freiburg, Germany; Dr. Howard Kelly, Baltimore; Dr. C. J. Gauss, Freiburg, Germany; Dr. Roswell Park, Buffalo; Dr. Dean D. Lewis, Chicago; Dr. John F. Binnie, Kansas City, and Dr. Jasper Halpenny, Winnipeg, Man., will speak. The evening of November 13 will be devoted to the consideration of cancer. The meeting will be held in Orchestra Hall. Dr. Thomas S. Cullen, Baltimore, will present the report of the Cancer Campaign Committee of the Clinical Congress of Surgeons of North America, and Mr. Samuel Hopkins Adams, New York City; Dr. Edward Reynolds, Boston; Dr. Frederick R. Green, Chicago; Mr. Frederick L. Hoffmann, Newark, N. J.; Dr. James Ewing, New York City; Dr. C. J. Gauss, Freiburg, Germany, and Dr. Joseph C. Bloodgood, Baltimore, will present papers and reports dealing with various phases of the subject. On November 14, in the Gold Room of the Congress Hotel, Dr. Hugh Cabot, Boston; Dr. Arthur Dean Bevan, Chicago; Dr. John M. T. Finney, Baltimore; Dr. E. Wyllys Andrews, Chicago; Dr. Charles H. Mayo, Rochester, Minn., and Dr. George W. Crile, Cleveland, will take part in the program.

In the division of surgical specialties, evening sessions will be held on November 11, 12 and 14 in the Louis XVI Room of the Hotel Sherman. On the first evening Dr. Edward Jackson, Denver; Drs. C. H. Beard, George H. Fiske, Chicago; Dr. Harold Gifford, Omaha; Drs. E. V. L. Brown and J. Brown Loring, Chicago; and Lieut. Col. Robert H. Elliott, I.M.S., superintendent of the Government Ophthalmic Hospital, Madras, India, will make addresses. On the second evening Dr. G. Hudson-Makuen, Philadelphia; Drs. W. E. Casselberry and Elmer L. Kenyon, Chicago; Dr. Viray P. Blair, St. Louis; Drs. Arthur D. Black and Herbert A. Potts, Chicago, will read papers. On the third evening Dr. Frederick Whiting, New York City; Drs. Frank Allport and Joseph Beck, Chicago; Dr. Philip D. Kerrison, New York City; Drs. George E. Shambaugh and J. Gordon Wilson, Chicago, will speak.

November 13, at 6 p. m., the Alumni of Rush Medical College will hold a dinner at the Hotel Sherman, which will be Rush Alumni headquarters during the congress. At the same time the Alumni of the College of Medicine of the University of Illinois will hold a banquet at the University Club, 76 E. Monroe Street. The headquarters of this organization will be the Illinois Club, 314 South Federal Street.

NEW YORK

Physician Wins Suit.—In the suit of Percy Palmateer, Spencerport, against Dr. Lewis E. Slayton, in which $30,000 damages was claimed on account of the death of the wife of the plaintiff from alleged mercurial poisoning, the jury decided in favor of Dr. Slayton.

Cancer Institute Opens.—The Hospital of the State Institute for the Study of Malignant Diseases, Buffalo, was formally opened November 1. Dr. Roswell Park, Buffalo, and Hon. Charles Fairchild, formerly Secretary of the Treasury, spoke for the trustees of the institute, and Dr. James Ewing, professor of pathology in Cornell University, delivered an address on "The Cancer Research Hospital."

Personal.—Dr. Frank W. Spaulding, Clifton Springs, is spending the winter on the Pacific Coast.——Dr. Joseph Moore of the staff of the Manhattan State Hospital has been appointed first assistant physician at the Matteawan State Hospital. Dr. Daniel W. Nead, medical examiner for the Pennsylvania System at Buffalo, has been transferred to be medical examiner at Reading, Pa., and Dr. John H. Brewster has been appointed medical examiner at Buffalo.

New Officers.—Medical Association of Central New York at Auburn, October 30: president, Dr. George M. Price, and secretary, Dr. John J. Buettner, both of Syracuse. Mr. Samuel Hopkins Adams addressed the association on "Quackery and the Public Press."——Physicians' Club of Batavia, October 23: president, Dr. Emerson E. Snow, and secretary-treasurer, Dr. Victor M. Rice.——Madison County Medical Society at Oneida, October 14: president, Dr. William T. Tanner; secretary, Dr. George W. Miles, both of Oneida.——Ulster County Medical Society at Kingston, October 7: president, Dr. Frank Keator; secretary, Dr. John R. Gillette, both of Kingston.——First District Branch of the New York State Medical Society at Yonkers, October 9: president, Dr. Henry Lyle Winter, Cornwall; secretary, Dr. Charles E. Denison, New York City.——Broome County Medical Society at Binghamton, October 7: president, Dr. S. Halsey Stevens, Union; secretary, Dr. H. De Witt Watson, Binghamton.

New York City

Celebrate Centennial.—The Riverside Practitioners Society held its one hundredth regular meeting and centennial dinner at the Hotel Manhattan, October 28.

New Instructors.—Drs. E. David Friedman, John H. Wyckoff and Mills C. Sturtevant have been appointed instructors in medicine in the University of Bellevue Hospital Medical College.

Dispensary Corner-Stone Laid.—The corner-stone of the new dispensary of the Hospital for Deformities and Joint Diseases on Madison Avenue and East One Hundred and Twenty-Third Street was laid with proper ceremony, November 4.

Lowest City Death-Rate.—The death-rate for this city for the week ending October 18, was the lowest ever recorded in the history of the health department. It was 11.20 per 1,000 population. The number of deaths for the week was 1,153, as against 1,243 for the corresponding week of 1912. One of the noticeable features of the report was the drop in infant mortality.

Seaside Hospital Inspected.—The Woman's Auxiliary of St. John's Guild made the arrangements for an inspection tour of the Seaside Hospital for Infants and Children at New Dorp, Staten Island, on October 29. As the pressure on the city hospitals is so great, the Seaside Hospital is to be kept open as a convalescent hospital during the winter season. The new wards provide for heart cases, orthopedic cases, maternity cases and general convalescents. One of the interesting features of the hospital organization is that it is conducted in neighborhood groups as far as possible.

Society to Celebrate Fortieth Anniversary.—The New York Laryngological Society will celebrate the fortieth anniversary of its organization this month. This society was the first of its kind to be established, antedating all societies in Great Britain or the continent by more than ten years. In 1898 the society was merged with the New York Academy of Medicine, becoming the Section of Laryngology and Rhinology. The formal meeting has been arranged to be held at the Academy of Medicine, at which addresses will be given and a bronze tablet and other memorials commemorative of the occasion will be presented.

OHIO

Public Health Service.—The state and municipal boards of health, together with the Anti-Tuberculosis League, will soon cooperate with the public health service in an investigation of tuberculosis in this city, which will include the relation of the disease to the various industries.

University of Cincinnati, Medical Department.—Not a little importance is attached to the appointment of Dr. Frank B. Cross, Tuesday, November 4, as vice-dean and secretary of the medical department. Dr Cross has acted as secretary of the Medical Civics Association since its origin, is a well-known ophthalmologist, and has done some very effectual organization work in medical circles in Cincinnati.

Personal.—The Cincinnati Academy of Medicine has elected Dr. Albert Freiberg, chairman of the Committee of Arrangements for the Mississippi Valley Medical Association, which will meet in Cincinnati next October.——Dr. Adolph Schmidt, Halle, Germany, addressed the Academy of Medicine, November 3, on "Diarrhea and Constipation." Dr. Schmidt has opened up new fields for the study of intestinal diseases by means of his original investigation, and has enriched medical literature with several very useful and comprehensive contributions. His address was clear, concise and full of interest to all present.

PENNSYLVANIA

Insane Asylum Dedicated.—The new state institution for the insane, located near Pottsville, was dedicated October 30. The new institution, when completed, will have cost approximately $600,000, and will accommodate 600 patients.

New Officers.—Central Pennsylvania Branch of the Jefferson Alumni Association at Altoona, October 16: president, Dr. Henry H. Brotherlin, Hollidaysburg; secretary, Dr. Charles F. McBurney, Altoona.——Somerset County Medical Society at Rockwood, October 21: president, Dr. George C. Berkheimer, Windber; secretary, Dr. Henry C. McKinley, Meyersdale.

Hospital News.—In a whirlwind campaign, $100,000 was raised for the General Hospital of Braddock.——The congregation of the Sacred Heart of Jesus, Allentown, has purchased the home of the late Judge Edward Harvey, and will establish a hospital to be conducted by the sisters of St. Francis.——The new tuberculosis hospital at the county poor farm near Connellsville was opened October 16.

Personal.—Dr. John L. Bower, medical examiner for the Pennsylvania System at Reading, has been transferred to be medical examiner at Broad Street Station, Philadelphia, vice Dr. E. C. Town, deceased.——Dr. Samuel G. Dixon, state health commissioner Harrisburg, who was operated on recently at the University Hospital, Philadelphia, is convalescent and has gone to Atlantic City.——Dr. Ivor D. Fenton has resigned as a member of the staff of the State Hospital, Fountain Springs, and will practice in Mahoney City.——Officers and employees of the department of health and charities, Pittsburgh, gave their former director, Dr. E. R. Walters, a complimentary banquet, at which he was presented with a 31-foot rowing shell.

Philadelphia

Personal.—Drs. Joseph M. Rosenthal and Wilfrid B. Fetterman were injured in a collision between the motor-car in which they were riding and a trolley-car, October 25.——Dr. James T. Rugh has been appointed consulting orthopedic surgeon at the Philadelphia General Hospital, vice Dr. H. Augustus Wilson, resigned.

Physicians as a Social Force.—At a reception given by the Medical Club of Philadelphia to President Hibben of Princeton University, October 17, he appealed to physicians to cooperate and help the social forces at work to-day to make saner men and minds through the elimination of degenerate social conditions.

Philadelphia Joint Lecture Course.—The Rush Society for the Correlation and Support of Medical and Biological Lectures in Philadelphia has entered into an agreement with the committees controlling the Mütter Lecture and the Weir Mitchell Lectures at the College of Physicians of Philadelphia, the lectures of the Philadelphia Pathological Society and the two lectures supported by undergraduate organizations at the University of Pennsylvania. In another year it is hoped that as a result of present efforts, this list of cooperative committees may be further extended to include the lecture of the John Morgan Society and the Gross Lecture of the Jefferson Medical College. The Samuel D. Gross Lecture, before the Philadelphia Pathological Society, October 23, opened the course. The next one will be the fifth Rush Society Lecture, on November 18, at 8:30 p. m., by Frederick L. Hoffman, of the Prudential Insurance Company of America, on "The Incidence of Cancer by Organs and Parts of the Body Affected," at the College of Physicians Building, Twenty-Second Street above Chestnut. The medical public is invited to attend.

TEXAS

Medical Buildings.—At the meeting of the Harris County Medical Society in Houston, October 3, the question of a medical office building for Houston was discussed.

New Public Health Association.—The Texas Antituberculosis Association, at its meeting in Austin, October 16, made arrangements to pay the debt on the Walter Colquitt Memorial Hospital for Tubercular Children, Galveston; pledged cooperation with the State Health Department and decided to change the name of the association to the Texas Public Health Association.

Hospital News.—The Physicians and Surgeons' Hospital has been organized at El Campo.——The Sherman Hospital has received its charter. At a meeting of the stockholders, October 10, Drs. E. J. Neathery and O. C. Ahlers were elected directors, and at a meeting of the directors Dr. Neathery was elected president and Dr. Ahlers secretary-treasurer. It was announced that the new building, which is being erected at a cost of $50,000, will be completed by December 15.

Medical Society Notes.—Dr. W. N. Wardlow, Corpus Christi, councilor of the Sixth Medical District, visited Kingsville October 9, and organized the Kleberg County Medical Society as a component society of the State Medical Association.——Dr. Orville Egbert, Beeville, has been elected secretary of the Bee County Medical Society, vice Dr. W. E. Sturgis, San Angelo, who has removed from the county.——The retiring chairman of the Fort Worth Physicians' Luncheon Club has named Dr. W. C. Lackey as chairman, Dr. Crittenden Joyes, vice-chairman, and Dr. Pierre Higgins secretary-treasurer.

Personal.—Dr. and Mrs. J. W. Harvey, Sunset, were injured by the overturning of their automobile, October 4.——Dr. H. G. Heanye, Corpus Christi, recently underwent an operation for appendicitis in Galveston, and is reported to be doing well.——Dr. Edward S. Ruth has been appointed instructor in anatomy and Dr. C. F. McClintic instructor in physiology in the medical school of the Southern Methodist University, Dallas.——Dr. Henry C. Hartman, formerly assistant state health officer, has been appointed professor of pathology in the State Medical College, Galveston, vice Dr. J. J. Terrill.——Dr. T. M. Sherman has been elected vice-president of the Farmers' Guaranty Bank, Kennard.

New Officers.—Eighth District Medical Association, at Wharton, October [illegible]: president, Dr. S. A. Foote, and secretary, Dr. P. E. Parker, both of Bay City. It was decided to hold the next meeting in conjunction with the Ninth District Medical Association at Houston.——Leon County Medical Society, at Marquez, October 14: president, Dr. S. R. Burroughs, Buffalo; secretary-treasurer, Dr. V. L. Smith, Jewett. The next meeting will be held in Buffalo.——South Texas Medical Association, thirty-fourth semi-annual meeting at Beaumont, October 10: president, Dr. E. F. Cooke, Houston, and secretary-treasurer, Dr. W. F. Thompson, Beaumont. The next meeting will be held in Port Arthur.

GENERAL

Tuberculosis Day.—Churches, schools, labor unions, fraternal orders and other organizations have been asked to join the antituberculosis workers of the country in the observance of the fourth annual national tuberculosis day, which has been set for November 7.

New Union District Officers.—At the annual meeting of the Union District Medical Association, held in Oxford, Ohio, October 25, the following officers were elected: president, Dr. D. W. Stevenson, Richmond, Ind., and secretary, Dr. William A. Thompson, Liberty, Ind.

Students of Criminology Organize.—At the meeting of medical, sociologic and psychologic scientists, held in Indianapolis, October 13, noted in The Journal of October 25, page 1547, the organization adopted the name of the American Association of Clinical Criminology.

Railway Surgeons Meet.—The Atlantic Coast Line Surgeons' Association held its seventh annual meeting in Montgomery, Ala., October 14 and 15, and elected the following officers: president, Dr. J. N. Baker, Montgomery, Ala.; vice-presidents, Drs. A. M. Brailsford, Mullins, S. C., and P. P. Lane, Waycross, Ga.; and secretary-treasurer, Dr. C. P. Aimar, Charleston, S. C. (reelected).

Anti-Disease Society Organized.—The New England Society for the Prevention and Treatment of Diseases was organized recently with an initial membership of twenty-five, and the following officers were elected: president, Dr. Andrew F. Christian, Boston; vice-president, Dr. Melville Jackson, Portland, Me.; secretary, J. J. Higgins, Boston, and treasurer, George L. Lupe, Boston. A series of twelve lectures, offered to the public, is being given on Sunday evenings at the hospital of Dr. Christian, Marlboro Street, Boston. The first lecture was given November 2.

Bequests and Donations.—The following bequests and donations have recently been announced:

University of Pennsylvania, Philadelphia, $50,000, by the will of Miss Anna Blanchard.

University of Pennsylvania, $15,000, to endow three beds in the children's orthopedic ward; Philadelphia Home for Incurables, $5,000, by the will of Mrs. R. L. Bringhurst.

For a new hospital to be erected at Albania, $10,113, in payments and subscriptions.

Hospital in China Needs Woman Physician.—The Board of Foreign Missions of the Presbyterian Church announces that a woman physician is needed for the Presbyterian Hospital and dispensary at Tsinanfu, Shantung Province, North China, 300 miles south of Peking. The hospital was opened in 1899, but has been closed periodically for the last three years owing to ill-health of the physician in charge, and a woman with thorough medical training, considerable experience and practice, a sound constitution and good health, good sense and tact, is urgently required. Support is said to be adequate, including salary, traveling expenses, living quarters, etc., and is provided by the mission board. Correspondence regarding this matter should be addressed to Wilbert B. Smith, 600 Lexington Avenue, New York City.

Award of Hodgkins Prize.—On the recommendation of the Committee on the Award of the Hodgkins Prize of $1,500 for the best treatise "On the Relation of Atmospheric Air to Tuberculosis," which was offered by the Smithsonian Institution in connection with the International Congress on Tuberculosis held in Washington in 1908, the institution announces that the prize has been equally divided between Dr. Guy Hinsdale of Hot Springs, Va., for his paper on "Tuberculosis in Relation to Atmospheric Air," and Dr. S. Adolphus Knopf of New York City, for his treatise "On the Relation of Atmospheric Air to Tuberculosis." The members of the Committee on Award were: Dr. William H. Welch, Johns Hopkins University, Baltimore, Maryland, chairman; Dr. Hermann M. Biggs, New York City; Prof. W. M. Davis, Cambridge, Mass.; Dr. G. Dock, Washington University Medical School, St. Louis, Mo.; Dr. Simon Flexner, Rockefeller Institute for Medical Research, New York City; Dr. John S. Fulton, Baltimore, Md., and Brig. Gen. George M. Sternberg, U. S. Army (retired), Washington, D. C.

CANADA

Infant Mortality in Ontario.—One out of every ten children born in Ontario dies before reaching 5 years of age. In 1912, 8,230 children under the age of 5 years died, of which 6,494 were under 1 year, a rate of 110.3 per 1,000 births. There were 200 less deaths from diarrheal diseases than in 1912.

The Fight against Tuberculosis in Ontario.—The death-rate from tuberculosis in Ontario continues to decrease. Although the reduction was less in 1912 than in several previous years, it is looked on with satisfaction. The deaths from tuberculosis in 1912 numbered 2,250, an actual decrease of 103. At the present time about 7 per cent. of the deaths in Ontario are due to tuberculosis. More die between 20 and 30 than in any other period.

Declining Birth-Rate in Ontario.—In the report of the registrar-general for Ontario, the birth-rate is shown as 22.4 per 1,000 for the past fiscal year, the lowest since 1903 and two points below that of 1912. This is in the face of the fact that the marriages show an increase of 3,038 in the year. The responsibility rests with the cities and towns. The cities had a record of 22,929 marriages, but were only able to report 15,917 births. The rural municipalities reported 10,910 marriages and 32,028 births.

President Godlee in Toronto.—Sir Rickman John Godlee, president of the Royal College of Surgeons, England, had the honorary degree of doctor of laws conferred on him at a special convocation of the University of Toronto, November 5. In the evening Sir Rickman was a guest at the regular monthly dinner of the Æsculapian Club, at which the Hon. W. J. Hanna gave an address on prison reform. At the Academy of Medicine on the evening of the 4th, Sir Rickman delivered an address on foreign bodies in the air passages. At the same meeting C. Franklin Hoover, M.D., Cleveland, read a paper on the clinical study of respiration.

Conference on Pollution of Navigable Waters.—Called at the instance of the Hon. J. D. Hazen, minister of Marine and Fisheries, a conference was held at Ottawa October 29, to determine on cooperative legislation enactments in the various provinces of Canada toward preventing the pollution of all navigable water-supplies. As contingent to this end, the conference passed a strong resolution calling for the immediate establishment of a federal department of public health. This resolution was proposed by Dr. E. P. Lachapelle, Montreal, chairman of the Quebec Board of Health, and seconded by Dr. M. M. Seymour, Regina, commissioner of public health for Saskatchewan, and president of the Canadian Public Health Association. Speaking to this resolution, the Hon. Martin Burrell could not give any definite announcement as regards a proposed federal department in the immediate future, as, although the matter had been discussed several times by the government, there were certain difficulties to be cleared up before the government could act in the matter. The jurisdiction between the provinces and the Dominicn had to be worked out before legislation could be passed. Dr. Charles A. Hodgetts, Ottawa, medical adviser to the Conservation Commission, advocated a federal act given into the hands of a central body to apply in conjunction with the provincial bodies.

LONDON LETTER

(From Our Regular Correspondent)

London, Oct. 25, 1913.

Noguchi's Demonstration in London

At a special meeting of the Royal Society of Medicine, Dr. Hideyo Noguchi gave a demonstration on "The Application of Cultural Methods to the Study of Infectious Diseases of Unknown Etiology." Noguchi's announcement of his discovery of the *Spirochaeta pallida* in the brain of subjects with general paralysis was listened to with great interest. Some beautiful microscopic specimens and lantern-slides were exhibited showing the organism in the brain tissue. He had transmitted it from the brain of a general paralytic to a rabbit, and had also produced in the rabbit by intracerebral or subdural inoculation, lesions resembling general paralysis. Lantern-slides were shown indicating that the spirochetes multiplied by longitudinal fission. Noguchi also drew attention to his lutein reaction for syphilis, which he considered superior to the Wassermann. He had cultivated three groups of spirochetes, of which the first two invaded the tissues and the blood, respectively, while the third was non-pathogenic and lived on the surface of mucous membranes or moist lesions. For the cultivation of the first two groups a piece of fresh sterile animal tissue was necessary in the culture medium. For the tissue spirochetes absolute anaerobiosis was necessary, which could be secured by an apparatus which he had constructed. But anaerobiosis was detrimental to the blood spirochetes, as a small amount of oxygen was necessary. Noguchi also showed cultures of the virus of poliomyelitis and rabies. He described the granules which he had found in pure cultures of the virus of rabies and believed to be the causal agent.

The Care of the Feeble-Minded

At the ninth quinquennial festival of the Royal Albert Institution, which is responsible for the care of the feeble-minded of the seven northern counties, Sir James Crichton-Browne gave an address on the future care of the feeble-minded. The etiology of mental deficiency was still obscure. At present the belief in its hereditary nature was uppermost and hopes were entertained that by segregation it might be reduced and even extinguished. But there could be no doubt that feeble-mindedness was a recessive character and might skip a generation. They could not shut up a man because his father or grandfather was weak-minded. There were also other causes besides heredity. It would almost seem as if the highest intellectual development in parents might sometimes result in mental deficiency in offspring. It was unquestionably desirable that a certain type of imbecile men and women should be segregated, the men for life and the women until 50 years of age; but it was erroneous to suppose that they would for a long time to come make any serious impression on the number of the feeble-minded in the community or on the mental caliber of the people at large. Along with heredity they must have regard to other causes of mental defect. The prevention of a large amount of it might be secured by improved sanitation in its widest sense, by skilled midwifery, by the hygienic rearing of infants and children, by the abolition or diminution of those zymotic diseases, scarlet fever, measles, etc., which left so many children blemished for life, by the timely treatment of defects of the senses and of various bodily illnesses, especially those of a tuberculous nature, by expert and discriminating teaching in schools of all classes, and the avoidance of that artificial production of stupidity which now sometimes went on, and by increased temperance and morality generally.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Oct. 24, 1913.

Deaths of Distinguished Men

Surgery in France has suffered a great loss in the death of Dr. Lucas-Championnière, which occurred October 22. He had been a member of the Académie des sciences for several months, and was present to read a paper on prehistoric trephination, which was on the program of the next meeting of the Institut de France, when he sank into his chair, overcome, probably by an embolism.

Born Aug. 15, 1843, at Saint-Léonard, Oise, Just Lucas-Championnière was intern in 1865, received his medical degree in 1870, and was appointed surgeon in 1874. He was chief of service at the hospitals of Cochin, Tenon, Saint-Louis and Beaujon, successively, and ended his hospital career as surgeon at the Hôtel-Dieu in 1906.

His chief interest had become focused on the method of antisepsis in 1868, when he was still an intern. In Scotland he met Lister, and became enthusiastic over a method which at that time was opposed or regarded with indifference. It was the glory of Lucas-Championnière to introduce antisepsis into France; he explained it and defended it against critics. He adhered to its principle in face of the progress in asepsis under Terrier and his successors. Antisepsis permitted Lucas-Championnière to undertake fearlessly a bolder surgery than that which had previously been practiced, and among his contributions to surgical progress were a perfecting of trephination, arthrotomy and the radical treatment of hernia. He also introduced the treatment of fractures by massage and early mobilization.

He was an active member of all the societies to which he belonged, and took a lively interest in free instruction. With other physicians and surgeons he founded in 1907 the Association d'enseignement médical des hôpitaux de Paris, and he gave clinical instruction to students. No one was worthier than he to occupy a chair at the Faculté de médicine, but though this distinction was denied him, his merit was none the less widely recognized. He had been a member of the Académie de médecine since 1894, and in 1912 was elected a member of the Académie des sciences, succeeding Lannelongue. He was editor of the *Journal de médecine et de chirurgie pratiques* and a member of the Association de la presse médicale francaise, and presided, at London, August 5, over the last meeting of the International Association of the Medical Press.

Dr. Ledouble, formerly professor of anatomy at the Ecole préparatoire de médecine de Tours, is dead from asphyxia by gas at the age of 65. Born in 1848 at Rocroy, Ardennes, he was intern at Paris in 1873, surgeon at Tours in 1878, and took the chair of anatomy at the medical school in that town in 1888. He became a corresponding member of the Académie de médecine de Paris in 1898, and an associate member in 1907. Ledouble published some remarkable anatomic studies on the variations of the muscular and osseous systems, works on prehistoric medicine and surgery, on hairiness in man, and on Rabelais and Bossuet.

Dr. Louis-Frédéric Wickham, formerly chief of clinic of diseases of the skin at the Faculté de médecine de Paris, and physician of the Maison de Saint-Lazare, is dead at the age of 53. He was a pioneer in the use of radium therapeutically, especially in the treatment of cancer.

First Congress of French-Speaking Pediatricians

In accordance with the decision made last year the annual session of the Association française de pédiatrie has been changed to the Congrès des pédiatres de langue française in order to permit foreign French-speaking physicians to take part in it. The congress was held in Paris, October 3 and 4, under the presidency of *Agrégé* Professor Netter of Paris.

OBESITY IN CHILDHOOD

Dr. Le Gendre, physician of the hospitals of Paris, believes that the obesity of childhood is almost always caused by arthritism and neuro-arthritism. The greater majority of obese children belong to families in which several generations have over-eaten and are the victims of weakened digestive powers. The prognosis of obesity in children is less grave than among adults affected to the same degree, as far as the immediate outcome is concerned. The serious feature is that the moderately obese child runs a great chance of becoming a very obese adult. The general indications of treatment are theoretically the same in children as in adults. The particular difficulties in the case of the child arise in the graver difficulty in appealing to the will. Exercise should play the greatest part in the treatment. The hour that follows the meal should be devoted not to exercise but to complete rest. The duration of exercise should be calculated and the amount should be divided throughout the day. Bicycling is useful and may begin at 6 or 7 years, if not carried to excess. Skipping the rope, running with the knees bent and the chest up, and hoop-rolling are exercises good for pulmonary ventilation. No new methods of diet have been developed recently, but there is a reaction against too monotonous diets. As for physical agents, except hydrotherapy and massage, which necessarily play a part in every complete cure, the electrotherapeutic method of Professor Bergonié offers an advantage in certain cases in which active exercise is difficult. (The Journal, Oct. 9, 1909, p. 1201.)

Dr. Marcel Nathan of Paris read a paper on glandular obesity, studying successive thyroid and genital obesity, hypophyseal obesity, pineal gland obesity and adrenal obesity.

Dr. G. Mouriquand, *agrégé* at the Faculté de médecine de Lyon, read a paper on the study of the syndrome described by Fröhlich in 1901 and characterized by a tumor (adenoma, carcinoma, etc.) of the hypophysis, accompanied by a monstrous general obesity and atrophy or delayed development of the genital organs. Patients affected by this syndrome have a high tolerance to carbohydrates. Often they are children of diabetic and glycosuric parents, and their syndrome thus contrasts with that of their parents. Theoretically, it would seem that the syndrome, which is due to hypopituitarism, ought to be benefited by the use of extracts of hypophysis. The drawback to preparations of this gland is that the activity varies greatly in accordance with the variable content of the gland, in active principles and the methods employed for extraction. Practically the physician will do well to use powders which have been altered by neither heat nor chemicals. The child tolerates well the dried and pulverized gland. Mouriquand has given as much as 0.3 gm. to little girls of 10 years and 0.2 gm. to a child of 2 years without bad results. The best practice seems to be to associate thyroid medication with the use of the hypophysis, or to alternate the two. Genital opotherapy may help out in case of failure. There have been some successes with radiotherapy.

Dr. Apert, physician of the hospitals of Paris, while recognizing that dietary restriction is useful, emphasizes the fact that it is not nearly so well borne by obese as by normal subjects, and this not only subjectively but objectively (lipothymia, weakness, etc.). He considers it an error to calculate the ratio of an obese patient on the scale of that of normal men. It is necessary to restrict diet progressively and without excess.

Dr. Guinon, physician of the Bretonneau Hospital, emphasizes the rôle of race and heredity in the etiology of obesity. The obese are abnormal not only in respect to their excessive fat, but because they are almost always unstable, emotional and restless. They often have osseous dystrophies (genu valgum, flatfoot, scoliosis). Guinon has employed thyroid and hypophysis treatment, but at present he dispenses with them and obtains about the same results.

Dr. Léopold-Lévi of Paris observed that the thyroid gland in therapeutic doses (0.2 gm. of dry powder, for example) has little effect on obesity. It increases the appetite and may thus fatten thin persons. Hypophysis treatment sometimes gives results, but it is on diet and physical exercise that one must rely.

According to Dr. Hallé, physician of the hospitals of Paris, there are cases of obesity in childhood in which the diet must not be too much restricted and in which there is danger in thyroid treatment. These are in lymphatic patients affected with adenitis and osseous lesions.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Oct. 17, 1913.

Personal

October 16, the noted gynecologist of Marburg, Professor Ahlfeld, celebrated his seventieth birthday.

Privat-dozent Dr. Lange of Greifswald has been selected as successor of Professor Bürkner in the directorship of the polyclinic for ear diseases in Göttingen.

Professor Gaffky has received the distinction of the title Wirkl. Geheimer Obermedizinalrat on his retirement from the Institute for Infectious Diseases, and has been appointed an honorary member of the Institute.

Restriction of Foreigners in German Universities

As a result of the overcrowding by foreign students, especially Russian, the Prussian Department of Education has determined that from now on a maximum figure shall be established which the students of any foreign nation shall not exceed. The Baden Department of Instruction has, in view of a threatened overfilling of the auditorium and laboratories, prescribed as the privilege of the native students that foreigners shall not be admitted to registration for lectures, and for the assignment for places for the winter semester previous to November 5, and for the summer semester May 5, and then only to the extent that places are available at these assigned dates.

Annual Meeting of the German Society of Urology

Two topics were presented by the executive committee for discussion, in addition to the numerous addresses made to the fourth annual congress which was held in the latter part of September.

SEROLOGY AND VACCINE THERAPY IN UROLOGY

This subject was introduced by Professor v. Wassermann. He noted the peculiar position of the uropoietic system in its biologic relation. In his view the tolerance of the tissues for infection is very closely connected with a local immunity. Moreover, he showed that there is in a therapeutic sense an extremely important distinction to be made between two different infectious conditions which bacteria may excite in the urinary apparatus, according as the infection is superficial or has penetrated deeply into the tissues. He showed from the success and failure of treatment of the coli and gonococcus infections of the urinary tract that only the deep infections furnish a satisfactory field for vaccine therapy.

George Michaelis, a coworker with Wassermann, presented the serologic principles of vaccine therapy as they were founded on Wright's discovery of opsonins and that of tropins by Denys and Neufeld. Finally he gave a short summary of bacterial infections of the urinary tract in which he made plain the necessity of the preparation of autogenous vaccines.

Volk of Vienna said that the favorable results reported by American observers from the employment of gonococcus serum needed confirmation. The vaccine treatment, which, with exact dosage and careful observation, is not injurious in any case, is suited not only to the treatment of various gonococcic complications, *but also to the various infectious diseases of* the urinary organs, particularly as a remedy auxiliary to the methods previously used. Acute gonorrheal urethritis is not influenced. The determination of the opsonic index is superfluous so far as treatment is concerned. More attention must be paid in the future to diagnostic vaccinations, and especially the combination of vaccine therapy with other methods and particularly with chemotherapy, must receive further development.

C. Schneider of Brückenau-Wiesbaden said that the entirely safe vaccination treatment of infectious processes of the urinary system means a marked advance over the previous methods of treating these diseases, and should be applied in all acute and chronic cases. Vaccine treatment should, if possible, be combined with local treatment, which is necessitated by the pathologic changes induced by the infection.

Asch of Strassburg stated that antigonococcus serum had failed in the treatment of gonorrhea, and that antimeningococcus serum was more satisfactory in gonorrheal arthritis with serous effusion. Vaccine treatment is successful in gonorrheal arthritis with a few exceptions. In funiculitis, periurethral infiltrates and acute septic gonorrheal processes, it often exercises a good influence, but not in prostatitis. In place of subcutaneous injections, which readily cause inflammation, Asch recommends the intramuscular injection of vaccines. The rise of temperature which follows such injections is of no value for diagnosis, as even healthy people may react with high fever. Gonococci are found in the urethral secretion after the injection when they were not previously demonstrable. For the diagnosis of late gonorrhea urethroscopy before and after the injection is recommended. From one to three days after such injections, striking lesions are to be found in the urinary tract which formerly appeared healthy. By this method gonococcus carriers can be converted into gonorrheics.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Oct. 15, 1913.

The International Congress on First Aid

In September, Vienna was the congress city of Europe for, apart from several less important conventions and meetings, two large gatherings of a scientific nature took place here — the convention of the German Natural Scientists and Practitioners (Deutscher Naturforscher und Aerztetag) and the Congress on First Aid and Ambulance (Congress für erste Hilfe und Rettungswesen). The latter being of more importance for the profession, it will be reported first. In order to systematize the proceedings, ten sections were formed, on first aid in accidents, first aid in towns and in the country, instruction of non-medical men in first aid, first aid in fire, in the mining and allied industries, in traveling, on the seashore and in navigation, and first aid in sport, in mountaineering, and in prevention of accident. More than two hundred papers were read, and over twelve hundred members were present.

Dr. Kuhn of Berlin read a paper on "Resuscitation of Persons Apparently Dead from Asphyxia." He postulates that artificial respiration and stimulation of the heart should be applied more frequently than it has been the custom hitherto. Experimental researches have shown that it is possible to obtain successful results in cases of poisoning with carbon dioxid or monoxid, or in drowning, lightning-stroke and electric shock. Especially the last-named two gave good prospects, even after hours, as proved by Hering. This man had succeeded in making human hearts beat eleven hours after he had removed them from the necropsy table. Similar observations were made by Kuliabko in hearts removed from children's bodies and in general anesthesia.

"First Aid in Alcohol Intoxication" was the subject of a paper by Mr. Windt. He pointed out that hitherto little had been done in this respect, as in the majority of cases persons found drunk in the streets were taken care of at the police station. These persons were patients, and should have the benefit of medical aid, as in over 50 per cent. there was complete loss of consciousness.

Sponge-fishing and its dangers were discussed by Dr. Flégel, who stated that over a hundred thousand souls directly found their living by this dangerous occupation. The old methods as used two thousand years ago were the safest: the trident, the search-rope or diving without any apparatus. These methods necessitated naturally that the work be done in shallow water with comparative safety. The adoption of modern methods (diving apparatus) enabled the men to work in greater depths, with the consequence of numerous fatalities, owing to derangements of the apparatus, and the rapid change of pressure of the surrounding medium (caisson disease). Except Austria-Hungary and Egypt, where the sponge-fishers are protected from these dangerous methods by the government, all other sponge countries (Greece, Turkey, India) had not yet found their way to do away with the dangerous system by law.

"First Aid and Prevention of Loss of Life in Navigation" was the title of a paper by Professor Hamm. Water-tight compartments arranged in the long axis as well as in the transverse diameter of a vessel were necessary, of course, with due regard to the stability. An important item was the relation of life-boats to the number of souls on board, not to the tonnage of the vessel. The water-tight compartments should not be considered at all in fixing the capacity of these boats. Careful consideration of the distribution of the cargo, the fuel and the storage of it, as well as the instalment of wireless telegraphy lessened the dangers on board a modern vessel. For every five hundred souls (or less) on board one doctor was necessary, and a ward besides a laboratory was advised for all ships taking long trips.

Aeronautics was discussed in several papers, of which one by Dr. von Schrötter dealt with the first-aid and prophylactic measures in high altitudes. He said that special precautions were needed in heights over 9,000 feet. The drop of temperature, of barometric pressure and of the oxygen content of the air were the chief dangers. An anointment of the skin exposed to the actinic rays of the daylight was necessary, and the eyes should be protected by preferably yellow-green — so-called "euphos"—glasses. Electric light, oxygen bulbs and life-belts (in flight over water) should be on board the air-vessel, as well as an emergency (first-aid) outfit. Great importance attaches to the perfect physiologic function of the heart, the ears and lungs. Loss of orientation might be caused by disturbance of the static organ, either by changes in the circulation or by the effects of the drop of barometric pressure. Another important point was the outlet of the motor from which the fumes could intoxicate the aeronauts, if carelessly adjusted. Smoking in hangars or in airships was absolutely dangerous. No person should approach an aeroplane (or balloon) about to descend. An apparatus for extinguishing fire should be at hand in all "air ports," as well as skilled medical help.

"First Dressing of Injuries" was the title of a paper by a member of the Vienna Ambulance Corps, Dr. Rosner. He emphasized the following rules: Fresh wounds should not be washed or probed; prolapsed organs should only be carefully supported (not replaced in the cavities of the body) and dressed with a simple dressing. Immobilization of fractures was a sine qua non in first aid. The first dressing should only enable the conveyance of the injured person to a hospital (or to his home). It should consist of a soft pliable, aseptic and absorbent substance. The first dressing was of paramount importance, especially on the battle-field. In all cases, however, reduction of luxations and fractures should be done as soon as possible, even on the scene of accident.

The sanitary precautions of the Austrian state railways were explained in a paper by Dr. Bagdan. Hospital cars and ambulance cars are running now on these lines, and a corps of male and female attendants is at the disposal of each district head office. First-aid boxes are carried in each express train, and for case of war or epidemics or large disasters usual freight-cars can be speedily converted into hospital-cars. A large, quite modern formaldehyd disinfection institute capable of holding two complete railway cars in the receiver is in service now. The cars will be disinfected in batches, and this method is said to be very cheap.

In connection with this congress, of which only the most interesting papers have been mentioned, there was an exhibition of appliances related to first aid: fire-outfits, smoke-proof outfits for firemen, modern instruments, statistics of accidents in factories, exhausters for dust-producing occupations and similar objects commanded the interest of those who had time to visit them. The majority of the members preferred to stay at the transactions and to help to organize an "International First Aid Committee," which will find means, after the model of the Red Cross, to render help in large disasters in a rapid and extensive way. This was the most important outcome of the congress.

BUDAPEST LETTER

(From Our Occasional Correspondent)

Budapest, Oct. 9, 1913.

How to Attain Old Age

Dr. Lorand Dezsö, in an address given before the Hygienic Society, said that the chances of attaining old age are much greater if we live much of our life in fresh country air. Statistics go to show, he said, for Budapest, Vienna and Berlin at least, that the fourth generation of the town dweller is unknown; but enough is currently reported to make the conclusion inevitable that the sine qua non of longevity is a certain amount of time spent in the country. The city child is subject to a number of disturbing conditions other than mere absence of creature comforts, which undermine the constitution by throwing too heavy a burden on the sense organs, through which exhaustion of the central nervous system follows; among these conditions are noises, a perpetual round of hurry, and unending sequences of incidents exhausting the attention, to which are superadded the physical discomforts of vitiated air and effluvia from human beings and waste organic products, besides offensive gases and infection-laden dust. To attain old age we have to relieve ourselves from worry, strains and anxieties, withdraw periodically from the whirl of effortful existence, modify our diet, omit the use of stimulants and narcotics, and spend reasonably long periods of time under pleasant conditions in practical retirement. Above all, amusements should be simplified and accepted rather than sought after. Only vegetable and semi-animal foods should be eaten.

Check on the Development of Mental Degeneracy

There are about fifty thousand persons of unsound mind in Hungary at the present day. Dr. Décsi has drawn attention to this fact in the medical society, adding the fact that more than one-third of this insanity is caused by syphilis and drink. He suggests the following rules for checking the development of mental degeneration at the present day: 1. Prevention of those who have been insane once from marrying. It may be stated as a certainty that many women who have had one attack of lunacy would have remained free from a second attack had they not married. 2. Immediate legislation for compulsory confinement of habitual drunkards, who are the greatest propagators of lunatics and degenerates, and who should therefore be legally restrained from inflicting their own vice on other human beings. 3. Prohibition of marriage by habitual drunkards. 4. Care in the administration of alcohol to women, as this very often makes the offspring a drunkard or a lunatic. 5. General reformation of the marriage system, with certain health requirements. 6. Prohibition of marriage when hereditary insanity exists on both sides. 7. Prohibition of marriage by paralytics, epileptics, consumptives and those affected with cancer. 8. Restriction of the liquor trade. 9. The establishment of intermediate houses, so to speak, where those suffering from acute, but curable, insanity, could be placed instead of being incarcerated in lunatic asylums. 10. Removal of all children born of nervous or neurotic parents from the influence of the parents, and from all home associations as soon as possible.

Marriages

Earl Warren Presley, M.D., New York City, to Miss S. Lois Exton of Arlington, N. J., at Poughkeepsie, N. Y., October 7.

Walter Stuart Woodruff, M.D., Mount Vernon, N. Y., to Miss Jessie Thurber Hequembourg, of Dunkirk, N. Y., October 18.

Thomas Russell Littlejohn, M.D., to Miss Mary Elizabeth Weeks, both of Pinewood, S. C., October 22.

Isaac Flavius Littell, M.D., to Miss Elizabeth Luckett Vance, both of Alexandria, La., November 3.

Allyn Bernard Moise, M.D., Shreveport, La., to Miss Edith Margaret Moore of New Orleans, October 22.

Robert M. Lowrie, M.D., Braddock, Pa., to Miss Laura R. Essick of Jerseytown, Pa., October 14.

Arnott Kell Duncan, M.D., Aldrich, Ala., to Miss Annot Vaught, at New Orleans, October 11.

Frederick Morris Frankfort Meixner, Peoria, Ill., to Miss Lillian Payne of Chicago, October 18.

Charles O. Burgess, M.D., Monmouth, Ill., to Miss Lura Harlin of South Bend, Ind., recently.

Lawrence Taylor Price, M.D., to Miss Louise Crutchfield, both of Richmond, Va., recently.

Hyman R. Wiener, M.D., Harrisburg, Pa., to Miss Belle Fried of Baltimore, October 22.

Edmund Russell Brush, M.D., to Miss Ruth Evans, both of Zanesville, Ohio, October 15.

Martha A. McCullough, to Nicholas Link, D.D.S., both of Dubuque, Ia., October 22.

Deaths

Hamilton Kelly Beatty, M.D. Jefferson Medical College, 1871; a veteran of the Civil War; superintendent of the bureau of health of Allegheny until the consolidation of that city with Pittsburgh; later deputy superintendent of the bureau of health, and superintendent of the bureau of sanitation of the Pittsburgh department of health; one of the original members of the staff of the Allegheny General Hospital; died at his home in Pittsburgh, October 6, from pneumonia, aged 65.

George John Kleinschmidt, M.D. College of Physicians and Surgeons, Chicago, 1906; formerly a Fellow of the American Medical Association; professor of anatomy in Marquette University, Milwaukee; for many years connected with the business management of newspapers in Milwaukee; died at his home in that city, October 12, aged 48.

John B. Grammer, M.D. Memphis (Tenn.) Hospital Medical College, 1894; a member of the Arkansas Medical Society, and formerly secretary-treasurer of the White-Cleburne County Medical Society; for more than twenty-five years a practitioner of White County; died at his home in Searcy, October 12, from angina pectoris, aged 51.

Byron B. Butler, M.D. Detroit College of Medicine, 1900; of Great Falls, Montana; surgeon for a construction camp of the Chicago, Milwaukee and St. Paul System between Great Falls and Lewistown; died in his camp office, September 27, from the effects of morphin, self-administered, it is believed, with suicidal intent, aged 34.

Armin Mueller, M.D. Wisconsin College of Physicians and Surgeons, Milwaukee, 1902; captain, Medical Corps, U. S. Army; a Fellow of the American Medical Association; died at Field Hospital No. 3, Texas City, Tex., October 14, from infection, following a compound fracture of the leg, aged 33.

William Arnold, M.D. Starling Medical College, Columbus, O., 1850; surgeon of the Thirty-Seventh Ohio Volunteer Infantry during the Civil War, thereafter a practitioner of Brownville, Neb., until 1884, and since that time a resident of Omaha; died at his home, October 3, aged 94.

Robert Devereaux, M.D. Jefferson Medical College, 1867; owner of the Cresson (Pa.) Water Company; president of the Cresson First National Bank; a member of the hospital corps of the army during the Civil War; died at his home, October 5, from disease of the liver, aged 68.

Charles Sinclair Elliott, M.D. Homeopathic Hospital College, Cleveland, 1886; professor of mental and nervous diseases and electrotherapeutics in Kansas City Hahnemann Medical College; neurologist to the Armour Home; died at his home in Kansas City, September 27, aged 50.

Frank W. Cartwright, M.D. University of the South, Sewanee, Tenn., 1903; demonstrator of practical anatomy in his alma mater; of New York City; a veteran of the Spanish-American War; died in the Reading (Pa.) Hospital, October 17, from acute nephritis, aged 36.

John D. Brundage, M.D. Yale University, New Haven, Conn., 1864; a member of the Medical Society of the State of New York; for twenty years a practitioner of West Hampton, L. I.; died at the home of his daughter in Goshen, Conn., October 21, aged 79.

George C. Butler, M.D McGill University, Montreal, 1865; of London, England; for thirty-seven years a practitioner of London, England, who arrived in Halifax, N. S., from England, July 17; died in that city July 19, from pneumonia, aged 61.

Harry Sumner Newlin, M.D. College of Physicians and Surgeons, Baltimore, 1883; a Fellow of the American Medical Association; surgeon to the McKeesport (Pa.) Hospital; died at his home in that city, October 19, from pneumonia, aged 54.

Per Emil Torgny Anderson, M.D. Rush Medical College, 1887; for many years a practitioner of Wahoo, Neb., but for the last two years a resident of his native city, Stockholm, Sweden; died in that city, September 19, aged 52.

Charles W. Baldwin, M.D. University of Nebraska, Lincoln, 1886; a pioneer practitioner of Douglas County, Nebraska; once a member of the state legislature; died at his home in Elkhorn, October 21, from pneumonia, aged 49.

Edward Terry Buck, M.D. Long Island College Hospital, Brooklyn, 1888; formerly a practitioner of Brooklyn and Indianapolis; was found dead in bed in a hotel in Indianapolis, October 19, from heart disease, aged 48.

Henry Thompson Peirce, M.D. College of Physicians and Surgeons, New York City, 1870; a member of the Medical Society of the State of New York; died at his home in New York City, September 27, aged 69.

Werner M. Bramigk, M.D. Fort Wayne (Ind.) College of Medicine, 1892; for many years a practitioner of Fort Wayne; died in his home in Detroit, Mich., September 27, from carcinoma of the throat, aged 53.

John Francis Marion Davis, M.D. Atlanta (Ga.) Medical College, 1860; of Choccolocco, Ala.; a Confederate veteran; died at the home of his daughter in Atlanta, September 27, from heart disease, aged 73.

Thomas J. Carpenter, M.D. University of Michigan, Ann Arbor, 1871; for many years an employee of the pension bureau, Washington, D. C.; died at his home in that city, September 17, aged 66.

Charles Albert Bemis, M.D. Jefferson Medical College, 1872; a member of the Massachusetts Medical Society; died at his home in West Medway, September 13, from cerebral hemorrhage, aged 70.

Frederick A. Hall (license, Kansas, 1901); a member of the Kansas Medical Society, and district surgeon for the Union Pacific System at Hoxie; died suddenly at his home, October 21, aged 60.

Sigmund Edward Bondy, M.D. Imperial Royal Karl-Ferdinand University, Prague, Bohemia, 1877; of Passaic, N. J.; died in Trenton, N. J., August 21, from pulmonary abscess, aged 54.

William Walton Black, M.D. Tulane University, New Orleans, 1871; for many years physician to the Fink and Poydras asylums; died at his home in New Orleans, September 19.

David Cowie (license, Florida); of New Smyrna; formerly a surgeon in the British Navy; died in the Shelter Sanatorium, New Smyrna, October 31, from senile debility, aged 82.

Olive Ophelia Nelson, M.D. Hahnemann Medical College, Chicago, 1900; a member of the Indiana State Medical Association; died at her home in Huntington, September 23, aged 53.

W. H. Denton (license, Tenn., 1910); of Reelfoot, Tenn.; a member of the Tennessee State Medical Association; was shot and instantly killed at Cherry, Tenn., October 12, aged 33.

Jeremiah Frazier Dively, M.D. Bellevue Hospital Medical College, 1876; of Pittston, Pa.; died at the home of his son in West Pittston, October 5, from cerebral hemorrhage.

Erastus Manford Drollinger, M.D. Eclectic Medical Institute, Cincinnati, 1878; died at his home in South Bend, Ind., October 2, from disease of the stomach, aged 60.

Robert W. Campbell, M.D. Washington University, St. Louis, 1873; for forty years a practitioner of Bowling Green, Mo.; died at his home, October 7, aged 68.

Washington B. Cousins, M.D. Western Reserve University, Hudson, Ohio, 1862; of Ashland, Ohio; died in the Samaritan Hospital in that city, October 12, aged 74.

William Benson Clowe, M.D. Hahnemann Medical College, Philadelphia, 1883; died at his home in Walla Walla, Wash., September 30, from nephritis, aged 67.

John Boston Britt, M.D. Jefferson Medical College, 1889; of Princeton, S. C.; died about October 18, and was buried at McCormick, S. C., October 20, aged 47.

Lewis Blanchard, M.D. University of Buffalo, N. Y., 1866; one of the oldest practitioners of Delaware County, Ia.; died at his home in Edgewood, August 5.

Charles A. Ayers, M.D. Hahnemann Medical College, Philadelphia, 1888; died at his home in Philadelphia, October 9, from cerebral hemorrhage, aged 61.

Madison James Conant, M.D. University of Michigan, Ann Arbor, 1888; died at his home in Tawas City, Mich., October 7, from bulbar paralysis, aged 54.

Rufus Childs, M.D. Meharry Medical College, Nashville, Tenn.; died at his home in Houston, Tex., about September 24, aged 45.

Alexander J. Erwin (license, Ohio, 1896); a practitioner since 1864; died at his home in Mansfield, October 9, aged 73.

Abram Orrinzer Allen, M.D. Rush Medical College, 1886; died at his home in Mountain Lake, Minn., October 19, aged 57.

John A. Bush, M.D. Louisville (Ky.) Medical College, 1890; died at his home in Greenville, Tex., October 23, aged 46.

Everett L. Day, M.D. Barnes Medical College, St. Louis, 1906; died at his home in St. Louis, August 29, aged 35.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

THE MEDICAL TIMES ADVERTISEMENTS

A Discussion of Some "Oversights" and the Ethics of Journalism

Two or three weeks ago we published letters from two physicians calling attention to an advertisement of a "cancer cure" hospital appearing in the *Medical Times*. As a result of THE JOURNAL'S comments, some of the physicians who were listed as "contributing editors" of the *Medical Times* wrote that they had requested that their names be withdrawn from this list. In reply to at least some of these letters, the editor of the *Medical Times* wrote asking them to reconsider their decision and offering as an excuse the statement that the appearance of the "cancer cure" hospital advertisement was an oversight. In this connection the following letter from the *Medical Times*, addressed to THE JOURNAL of the American Medical Association, is pertinent:

> "*Gentlemen*:—We note in your issue of October 18 an article calling attention to an advertisement which appears in the columns of this journal, and to which your editor rightly objects.
>
> "The advertisement in the *Times* was the result of an oversight, and it will not reappear.
>
> "While we are indebted to you for thus bringing the matter to our attention, we cannot but feel that a letter written to us would have been more in keeping with the ethics of journalism.
>
> "Very truly yours, THE MEDICAL TIMES."

It will be noticed that this letter, like the letters sent to other physicians, ignores altogether the most important point made by THE JOURNAL in its criticism of that publication's advertising policy. THE JOURNAL said in this connection:

"If our correspondents will go through the advertising columns of the *Medical Times* they will find many, many other frauds, less cruel perhaps than the Kellam advertisement, but no less disreputable or discreditable to the medical profession."

The *Medical Times* apologizes for the advertisement of the Kellam Cancer Cure Hospital but ignores altogether the fact that the hospital advertisement was but one of many equally discreditable. We turn to recent issues of the *Medical Times* and we find it fairly reeking with advertisements of proprietary preparations that are a disgrace to the medical profession, many of them having been repeatedly exposed in THE JOURNAL. We find, for instance, a quarter-page advertisement of the Expurgo Manufacturing Company. "Expurgo Anti-Diabetes," we are solemnly told in the pages of the *Medical Times*, is:

> "The only reliable and thoroughly tested remedy for the cure of Diabetes Mellitus and Insipidus."

This wretched fraud, which also is advertised in true "patent medicine" style direct to the public, is presented to a presumably intelligent profession as a "cure" for a disease which so far has baffled the best brains in the scientific world.

"Expurgo Lapis" we are told, also via the *Medical Times*, is:

> "The only known cure for gall-stones, kidney and bladder stones, gravel and all kidney trouble arising from uric-acid origin.'

Did Kilmer's Swamp-Root ever claim more? "Diabetes is no longer an incurable disease" runs the advertisement of the Jireh Diabetic Food Company, yet the editor of the *Medical Times* must know that in THE JOURNAL[1] and in the reports of state chemists the Jireh diabetic foods have been shown time and again to be among the most dangerous and fraudulently exploited products sold to the unfortunate diabetic.

Phenalgin,[2] twin brother to the Antikamnia fraud, shouts its inferential falsehoods in a half-page display. Micajah's

[2] Propaganda for Reform, Ed. 8, pp. 10 and 267.

Wafers,[3] the alum-borax mixture long advertised as a cure for gonorrhea, endometritis, etc., may also be found, as well as many other preparations exposed at various times by THE JOURNAL. For example: Anasarcin[4], Campho-Phenique,[5] Papine,[6] Bromidia,[7] Cactina Pillets,[8] Pluto Water,[9] Prunoids,[10] Sanatogen[11] and Sal Hepatica.[12]

What excuse can the *Medical Times* offer for the presence of these frauds in its pages? Are these, too, "the result of an oversight"? Presumably for thus bringing to its attention these various *other* disreputable advertisements, THE JOURNAL will be accused again of violating "the ethics of journalism." If calling attention to fraudulent advertisements is out of keeping with the ethics of journalism, *what*, pray, must be said of the publications that are willing to share in the profits of such fraudulent exploitation? But, and we cannot repeat it too often, the *Medical Times* is but *one of a class*, neither worse *nor* better than many other medical journals whose financial support comes from the proprietary interests rather than from the medical profession. The responsibility for the *existence of these journals really rests not on the business* men who conduct them on a commercial basis, but on the physicians *who tolerate* or encourage them in any way.

"A CONTRAST IN MEDICAL PUBLICATIONS"

Under this title *The Journal of the Oklahoma State Medical Association*, in its October issue, comments pertinently, thus:

"Last month we had the pleasure of calling attention to the high class of *The Journal of the Southern Medical Association* and its advertising pages.

"We regret to have to note a contrast on analyzing a journal familiar to many Oklahoma readers. The *Medical Herald*, the official organ of the Medical Association of the Southwest, has long been an object of comment for its laxness in the acceptance of questionable advertising. That this laxness will eventually build up a defense for inferior products and render the physician users of them callous along ethical lines is evident from the tenor of editorials in this publication.

"The August issue of the journal contains a criticism of the Carnegie Foundation and the American Medical Association in their efforts to improve the condition of our medical colleges.

"The writer of this editorial, Dr. T. D. Crothers of Hartford, Conn., a contributing editor, bemoans the fact that the medical colleges of the United States have been reduced to 117; that it is proposed to make a reduction of twenty-five more. Dr. Crothers objects to reports of inefficiency of the medical institutions, but suggests no remedy.

"In the September issue of his journal he objects to the method of publication of papers in THE JOURNAL of the American Medical Association, and intimates that there is a trust or combination for the purpose of limiting the output of that journal to those who are popular with the section officers.

"It is a notorious fact that preachers often overlook their greatest field of activity in their own immediate circle. That reformers overlook *in their own neighborhood a fertile field* for work, and in this connection we have only to call attention of this able man to his own medical publication, and, incidentally, we desire also to call the attention of the Oklahoma readers to the advertising columns of this journal and have to suggest that they use their influence to reform its advertising pages.

"The August issue contains the advertisements of sixty-four drugs or compounds; *of the sixty-four, fifty-five have either* not been accepted by the Council on Pharmacy and Chemistry of the American Medical Association, have been thoroughly tested and failed, or found wanting in various degrees.

"Among the oldest offenders, we find Anasearin, Cactina Pillets, Hayden's Viburnum Compound, Triacol, Farwell and Rhines Gluten Flour, Pepto-Mangan (Gude), Nephritin, Sinkina and many others.

"Dr. Crothers is an alienist and neurologist, we understand, of some note. We wonder how much 'Neurilla,' manufactured by the Dad Chemical Company of New York, he uses in his practice? How much 'Neurosine' he orders dosed out in his Hartford hospital? An inspection of the advertising pages of this journal with which he is connected will convince anyone that it is a most notorious offender against ethics in carrying these advertisements to the medical profession existing to-day in this country. We note advertisements of compounds that were guilty of various shortcomings more than ten years ago, and that have not improved in that time. A great many of the fifty-five undesirable compounds have been criticized either by direct report of the Council or editorially in THE JOURNAL of the American Medical Association more than once. Most of them are known to be rank frauds, others claimers of virtues that never existed, the remainder just indifferent products.

"Just as long as the unthinking physician supports these medical publications by subscribing for them, or using the products advertised in them, he will continue to do himself an injustice, and ofttimes a severe one. We prayerfully commend the advertising pages of the *Medical Herald* to Dr. Crothers and suggest that there his explosive activity will find something worth working on."

THE FRIEDMANN "CURE"

Two Letters — Take Your Choice

EISNER-MENDELSON CO.
90 WEST ST. NEW YORK

October 31, 1913.

To the Editor:—An item appears in your issue of October 25, wherein it is stated that the Eisner-Mendelson Company was *reported to have* bought the rights for the Friedmann vaccine. This impression is entirely erroneous, and it was stated by us publicly at *the time that* the Eisner-Mendelson Company has *no* interest in this matter at all. We will thank you to kindly correct this item.

Yours very truly,
EISNER-MENDELSON Co.
per William J. Eisner.

A. E. BUTLER & CO.
Members Chicago Stock Exchange, Stocks and Bonds
116 SOUTH LA SALLE STREET, *CHICAGO, U. S. A.*

Dr. ———, May 15, 1913.
R———, *Illinois.*

Dear Sir:—We would like to call your attention to the Eisner-Mendelson Co. *preferred stock, which for the past* eight years has paid 8 per cent. on its par value *($10.00).*

THIS COMPANY HAS LATELY ACQUIRED THE FRIEDMANN CURE FOR CONSUMPTION;[1] *and where opinions differ as to the merits of this serum, it can in* no way impair the present *earning* capacity of the company, but, on the contrary, may increase its earning power materially. The preferred stock in this *company can be bought now at about $9 per share, netting* approximately 8.09 per cent. on the investment. The principal stockholders are doctors and dentists.

We have a *limited amount of this stock which* we believe we can procure if you desire same, and if so, *would suggest* your sending Chicago exchange through your local bank *to* their Chicago correspondent, instructing them to turn money *over to us on the delivery of the* number of shares you ordered. Kindly advise us at the same time.

Awaiting the pleasure of hearing from you, we are

Yours very *truly,*
A. E. BUTLER & Co.

Correspondence

A Method of Securing Qualified Men

To the Editor:—A civil service examination for health director of the city of Oakland, Cal., was conducted under the auspices of the U. S. Public Health Service, with the permission of Surgeon-General Rupert Blue, in cities in which the service had stations. The examination was held on July 30 and 31, and was conducted by the civil service board of Oakland for all applicants residing in the state of California.

The board was fortunate in securing the aid of an advisory committee to assist it in preparing the questions and checking the examination papers. The committee consisted of Dr. E. N. Ewer, health officer of the city of Oakland; Dr. H. G. Thomas, Oakland; Dr. W. F. Snow, secretary of the California State Board of Health; Dr. W. A. Sawyer of the State Hygienic Laboratory, and Prof. C. G. Hyde of the University of California.

The civil service board received twenty-seven applications from physicians in various parts of the United States. The requirement that the health director must give his entire time to the city's business naturally limited the aspirants to men who are particularly interested in public health work. Nineteen men took the examination, of whom eleven passed.

Under the charter of the city of Oakland, the three men whose names are highest on the eligible list must be certified to the appointing power by the civil service board. The appointing power has the privilege of selecting any one of these men to fill the position.

Dr. Richard G. Brodrick of San Francisco passed highest on the list with a percentage of 94.3. Dr. Brodrick is the present health officer of the city and county of San Francisco, and has held this position for a number of years.

Dr. Norman E. Williamson of Lahontan, Nev., is second on the list with a percentage of 83.7. Dr. Williamson is in the United States Public Health Service and was for four years in charge of one of the health districts in the Panama Canal Zone.

Dr. Allen F. Gillihan of Berkeley, Cal., is third on the list with a percentage of 82.9. Dr. Gillihan is president of the Board of Health of the city of Berkeley and has devoted a large amount of time to the study of public health work.

Frank Colbourn, Oakland, Cal.,
Acting Secretary, Civil Service Board.

The following are the questions used in this examination:

WRITTEN EXAMINATION (TIME, FOUR HOURS)

1. Discuss diphtheria, bubonic plague, epidemic cerebrospinal meningitis, small-pox, measles and tuberculosis, under the following heads:
   (a) Methods of transference to human beings.
   (b) Periods of incubation.
   (c) Methods of defense against the disease.
   (d) Methods of control of its spread.

2. How would you investigate an outbreak of typhoid fever with a view to discovering its source? Devise an inspector's data blank for such an investigation. Outline instructions which should be issued to the public and to physicians.

3. How should a health officer proceed in making a survey to determine the prevalence of (*a*) malaria, (*b*) hookworm disease?

4. Outline, and give reasons for, a set of rules which you would consider reasonable for the control of (*a*) scarlet fever and (*b*) epidemic poliomyelitis, in the present state of our knowledge regarding these diseases.

5. Criticize the value of formaldehyd fumigation of dwelling-rooms after tuberculosis, diphtheria, yellow fever and measles.

6. What clinical and laboratory findings would you expect in a case of human bubonic plague, and how would you obtain your material for examination?

7. Discuss the relative responsibilities of city, county and state authorities for the supervision of a city milk-supply. Give details for the practical administrative control of the quality of such a milk-supply.

8. Of what benefit to the public health is an efficient meat- and market-inspection service?

9. Many cases of occupational diseases and industrial accidents occur annually in the United States. Name several of these diseases and common accidents and outline a constructive program for their prevention.

10. Outline the approved methods of disposal of the following classes of municipal refuse, severally and in groups: garbage, rubbish, street-sweepings, ashes, dead animals.

THESIS (TIME, FOUR HOURS)

Write an original discussion, not to exceed three thousand words, on the subject of "School Inspection."

The following information regarding Oakland is furnished in order that the candidate may acquaint himself with the more important facts.

The city of Oakland has fifty schools providing for the usual primary, grammar and high-school grades. Most of the buildings are less than 10 years old and several, including one high school, are under construction at the present time. The older buildings are of two and three stories, the newer ones have the rooms all on one floor and provide in part for open-air classes. Several are of the patio style of construction. The department employs the whole time of one physician, whose title is Superintendent of School Hygiene, and the whole time of seven trained nurses. The superintendent of school hygiene, besides attending to the usual duties of such an official, delivers lectures to the boys in the high schools on sex hygiene and kindred subjects. These subjects are taught to the girls by a woman physician who is also in the active practice of medicine.

EDUCATION AND EXPERIENCE

1. State your age, birthplace and present address.

2. What high-school and college education did you have before studying medicine? Give names of institutions, dates of attendance and degrees conferred. State fully.

3. Give a statement regarding the nature of your college work in (*a*) biology, (*b*) other subjects.

4. Give the name of the medical college which you attended, dates between which you were in continuous attendance, the degrees conferred and the dates when the degrees were received.

5. Give a statement regarding any special training in public health which you received in the medical school. State fully.

6. Describe your hospital experience (*a*) as intern or extern. (*b*) as visiting physician. Make special mention of your hospital training in communicable diseases. Name the hospitals and state their location. Answer fully.

7. What experience have you had in executive work?

8. What practical experience have you had in public-health work?

9. State any special experience, not already mentioned, which would be of value in the position for which you are applying. Mention any experience in teaching or research in medicine or public health.

PERSONAL QUALIFICATIONS (ORAL)

1. What use would you make of the laboratory in your administrative work as the health officer of a city?

2. Given a case suspected of being leprosy. With what diseases might the disease be confused? How would you reach a decision regarding the diagnosis?

3. Name the several preparatory methods of treating municipal sewage and the several methods by which raw or treated sewage may finally be disposed of.

4. What methods do you consider most effective in reducing the prevalence of venereal diseases?

5. What practical measures do you consider the health officer can institute to insure complete birth and morbidity returns?

Method of Sterilizing (?) Rubber Gloves

To the Editor:—A method of sterilizing (?) rubber gloves by means of 2 tablets (weight not given) of mercuric cyanid in 4 ounces of alcohol and 4 ounces of talc is recommended by Dr. Ray Ernest Smith in The Journal, Oct. 18, 1913, p. 1475. The solution is poured over the gloves, and they are removed and left to dry in a sterile towel. The time of application of the germicidal fluid is not given.

This method of sterilization is useless. Mercuric cyanid has been shown in my own experiments to have no action on most of the pus-forming organisms, particularly *Staphylococcus pyogenes aureus*. Harrington of Boston (*Boston Med. and Surg. Jour.*, Jan. 14, 1904) had a similar experience in obtaining no germicidal effect from mercuric cyanid after thirty minutes with a 1:500 solution, after which he desisted and considered the salt useless. Organic matter still further lowers the germicidal action. Dr. Smith's method is therefore useless. The alcohol may have a slight effect, about the same as the cyanid.

The way to sterilize rubber gloves is to boil them in water or glycerin or put them in the autoclave at a temperature of 120 C. (248 F.), with a pressure of 15 pounds for thirty minutes. Steam at 100 C. (212 F.) without pressure will not do it. They may be boiled and kept in glycerin conveniently.

The mercuric salts, bichlorid, iodid and cyanid, in the presence of organic matter, such as blood, pus, serum, soap or skin, are ineffective because they are neutralized and the insoluble albuminate is formed. Bichlorid is very strong under test-tube conditions; but, if organic matter is added, the salt retains no germicidal effect whatever. This has been repeatedly proved, as, for example, by Gebbert, who grew cultures after a fifteen-minute application of mercuric chlorid solution, 1:1,000, in the presence of albuminous fluid. Somerville and Walker (*Med. Press*, Feb. 14, 1906), also showed that, by the addition of organic matter, the germicidal value of mercuric chlorid dropped much below that of phenol (carbolic acid) in equal strengths. Anthrax spores grew after fifteen-minute treatment with mercuric chlorid, 1:120.

Conditions of practice are such that disinfection by the mercuric salts must always be done in the presence of organic matter, soap, serum, blood, pus, skin or mucous membrane. All of these render the mercury salts ineffective and useless. How long will surgeons persist in the vain delusion that they can sterilize their hands with solutions of these salts? They are worse than useless in that they create a false sense of security and a belief in their germicidal value, which would be naive were it not pathetic and serious in its practical results. If there is any degree of uselessness, cyanid is the worst.

Ellice McDonald, M.D., New York.

Mishaps Under Salvarsan

To the Editor:—Since the introduction of salvarsan three and one-half years have passed. During this period there have been reported in the literature about two hundred fatalities and the occurrence of blindness, deafness, hemorrhagic encephalitis, paralysis, epileptiform convulsions and severe intoxication following its use. As many physicians are not in the habit of writing for publication, and as others shrink from any publicity in regard to cases of syphilis in their private or contract practice, or for other reasons, many of the deaths and mishaps from the use of salvarsan have not been published. Therefore, I ask those physicians who have had any experience with deaths, blindness, paralysis, etc., or any of the other severe menacing disturbances following salvarsan, to send me brief clinical reports in order that I may compile comprehensive statistics. In making use of the material the names of the physicians supplying the information and their place of residence will not be mentioned. It is without doubt of the greatest importance that these hitherto ignored instances shall be collected, in order that there shall be placed in the literature such information that a decision can be made as to the actual harmlessness or the danger of salvarsan. Please address: W. H. Dreuw, M.D., Potsdamerstrasse 31 a, Berlin, Germany.

[The foregoing is a translation of a German letter just received from Dr. Dreuw. He is a dermatologist, one of the collaborators on the *Dermatologische Wochenschrift*, published by Unna of Hamburg.]

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TOXICITY OF THORIUM

To the Editor:—Will you please inform me whether or not thorium, the radio-active metal, is a poison? If it is a poison, what is its physiologic action? What is the maximum and minimum dosage?

A. H. Jahn, M.D., Pittsburgh, Pa.

Answer.—Metallic thorium and its insoluble compounds, such as the oxalate and dioxid, are non-toxic. Some experiments have been made with them (oxalate) in the attempt to control vomiting, and (metal and dioxid) in roentgenographic work in the gastro-intestinal tract. In general the results were not markedly superior to those obtained with bismuth compounds. In the Roentgen-ray work 30 gm. of the metal have been administered daily without toxic effects. A pharmacologic study of thorium salts has been made by Chase and Gies and by Sollmann and Brown (*Am. Jour. Physiol.*, 1907, xviii, 426 and 457).

Aqueous solutions of thorium salts precipitate proteins and protoplasmic materials in general, blacken and precipitate blood, bleach and harden muscle and harden and shrivel practically all tissues. They have no appreciable effect on the unbroken skin. Thorium nitrate has the properties of an astringent irritant. Its irritant effects can be avoided by dissolving it in a solution of sodium citrate. Its toxicity is very low. At one time thorium nitrate was described in New and Nonofficial Remedies as a non-proprietary article. The following statement in regard to its action and usage was given:

"The soluble thorium salts bear a close resemblance to alum in their local astringent and irritant properties. They are not absorbed from the alimentary canal. Hypodermically they cause local sloughing, and intravenously they kill by coagulating the blood. The non-precipitant double salts are practically non-toxic, even intravenously. They are excreted by the kidneys. Thorium salts are fairly radio-active. They have been recommended for local application in malignant diseases and thorium emanation has been inhaled in phthisis. Reliable evidence as to the therapeutic value of thorium salts is lacking."

The eligibility of thorium nitrate having been questioned, the committee which looked into the matter reported that the substance appeared to be little used and that its retention in New and Nonofficial Remedies was not justified. Accordingly the description of the product does not appear in New and Nonofficial Remedies, 1913.

RELIEF OF HEADACHE AFTER POISONING BY ILLUMINATING-GAS

To the Editor:—What are the quickest and most efficient remedies to relieve the intense headaches as a consequence of illuminating-gas poisoning? Kindly give the names of the drugs, in their relative order of efficiency, the doses and frequency of administration, and also state which one has been found the most reliable. I should also be glad to have a detailed account of treatment and any other available data.

R. H. Kilduffe, M.D., Philadelphia.

Answer.—Articles on the treatment of gas poisoning make little reference to headache. We have been able to find only the following:

Peterson and Haines ("Legal Medicine and Toxicology," ii, 655) state that the inhalation of oxygen prevents the headache subsequent to poisoning.

Robin (*Gaz. méd. belge*, 1909, xxii, 79, abstr., The Journal, Dec. 18, 1909, p. 2116) warns against using the ordinary remedies for headache which may impair the blood and says that morphin should be the main reliance. Caffein and strychnin should be used if tonics seem to be indicated.

The following references to the treatment of illuminating-gas poisoning may be consulted:

McConnell, J. W., and Spiller, William G.: A Clinicopathologic Study of Carbon Monoxid Poisoning, The Journal, Dec. 14, 1912, p. 2122.

SODIUM FLUORID IN ABDERHALDEN'S SERODIAGNOSIS FOR CANCER

To the Editor:—I note with much interest your editorial on "Abderhalden's Test in Cancer" (The Journal, Oct. 18, 1913, p. 1461). I should appreciate reference to articles giving the sodium fluorid technic. I have used the regular Abderhalden technic, with plain distilled water and cancer tissue in a dozen or more cases, with favorable results, but am not acquainted with the technic to which you refer.

Clarence F. Ball, M.D., Rutland, Vt.

Answer.—Erpicum (*Bull. de l'Acad. roy. de méd. de Belg.*, 1913, xxvii, 624), used the following method: The serum from the suspected cancer patient is obtained in the usual way with the usual aseptic precautions. The fragments of cancer tissue (1 cm. in diameter) are boiled in about twenty times their volume of water for ten minutes; a sample of this water is now tested for the biuret reaction, and if a positive result is obtained the fragments of tissue are bathed in distilled water with 3.5 per cent. sodium fluorid until the liquid no longer gives the biuret reaction. A bit of tissue is now placed in the dialyzer, 2 c.c. of serum are added, and the dialyzer introduced into a suitable bottle or vessel containing a 1.5 or 2 per cent. sodium fluorid solution and the whole is kept at 22 C. (71.6 F.) for thirty-six hours. A control dialyzer without the cancer tissue is prepared in the same way. Whether or not any new substances—peptones, etc.—have appeared in the fluid outside the dialyzer is determined by the biuret reaction and other methods. Erpicum used the biuret reaction. He obtained the biuret reaction only once with the water in which he boiled the cancer tissue preliminary to dialysis, and once as the result of contamination with the serum in the control dialyzer. Sodium fluorid is used in such experiments as these because in the concentrations mentioned it is germicidal without affecting enzymatic processes.

THE ITALIAN PHYSICO-CHEMICAL ACADEMY AND THE SOUTHERN CALIFORNIA PRACTITIONER

To the Editor:—1. I enclose a communication from the "Italian Physico-Chemical Academy" advising me of election to this "academy" as honorary member. Will you be good enough to inform me if anything is known of this academy, whether it is first-class and has any standing among European scientific societies, etc.? I do not intend to be "stung," nor do I want to pass a good thing.

2. Also, is the *Southern California Practitioner* of Los Angeles (Dr. George E. Malsbary, editor) all right? He is asking for an abstract of a recent paper of mine to be paid for in the form of five yearly subscriptions worth $10 sent to five persons I shall name. Sorry to trouble you, but both of these propositions sound "fishy."

HENRY W. BURNETT, M.D., Providence, R. I.

ANSWER.—1. Our correspondent's suspicions regarding both the "academy" and the medical journal are well founded. The propositions *are* "fishy." The Italian Physico-Chemical Academy is, as we have repeatedly stated, a fake institution whose chief purpose seems to be that of selling membership certificates to the gullible. The thing was written up in THE JOURNAL, Oct. 21, 1911, under the title "Bogus Scientific Institutions"; it was also referred to in the Berlin Letter of the same issue. Again our readers were warned in the issues of May 11, 1912, p. 1455, March 8, 1913, p. 770, and May 10, 1913, p. 1480.

2. The scheme that certain medical journals work for the purpose of obtaining a subscription list that will pass muster with the postal authorities by offering to pay for an abstract with a certain number of subscriptions was referred to in THE JOURNAL, Oct. 11, 1913, p. 1391, and Oct. 18, 1913, p. 1473.

TREATMENT OF PELLAGRA

To the Editor:—Is there any specific treatment for pellagra? If not, kindly tell me what has proved the most effectual.

R. W. WILEY, M.D., Salem, Va.

ANSWER.—Most authors agree that there is no specific treatment for pellagra, but some assert that the one drug which is most effectual is arsenic. Arsenic has been tried in various forms, including, in addition to the ordinary official preparations, atoxyl, sodium cacodylate and salvarsan. None of these appears to have produced such results that it can be regarded as a cure for the disease. Niles recommends arsenite of iron given by hypodermic injections and sodium cacodylate in doses of ¾ grain, injected on alternate days under careful aseptic precautions. Proper diet and proper hygienic conditions must be provided. Hydrotherapy is regarded as very useful by some, and others have recommended the transfusion of blood from those who have recovered from the disease. This method, however, has received only a limited application.

RUSSIAN MEDICAL JOURNALS

To the Editor:—Please name some Russian medical journals and places of publication.

M. WEINSTEIN, M.D., Rockaway Park, L. I.

ANSWER.—The following are among the leading Russian journals, with addresses of subscription offices:

Russky Vrach, Nevskii 14, St. Petersburg, Russia. Weekly; about $7 a year.

Meditsinskoe Obozrienie, Arbat Dom Obshestva Russkich Vratchi, Moscow, Russia. Semimonthly; about $5.25 a year plus postage.

Pediatria, 31 Nikolaevskaya, St. Petersburg, Russia, Monthly, about $3 a year plus postage.

STATES WITH WHICH PENNSYLVANIA RECIPROCATES

To the Editor:—Please tell me with what other states the Pennsylvania State Board reciprocates. SUBSCRIBER.

ANSWER.—Pennsylvania has established reciprocal relations, on the basis of an examination only, with Illinois, Indiana, Louisiana, Nevada, New Jersey and Ohio. The Bureau of Medical Education and Licensure of Pennsylvania is given authority in its discretion to accept certificates of license issued by other states in lieu of an examination when those states accord a like recognition of licenses issued in Pennsylvania.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Regular, State Capitol Bldg., Little Rock, November 11-12. Sec., Dr. W. S. Stewart, Suite 404 Citizens Bank Bldg., Pine Bluff; Homeopathic, Little Rock, November 11. Sec., Dr. Ida J. Brooks, E. 10th St.; Eclectic, Little Rock, November 11. Sec., Dr. C. E. Laws, 712 Garrison Ave., Ft. Smith.

CONNECTICUT: Regular, City Hall, New Haven, November 11. Sec., Dr. Charles A. Tuttle; Homeopathic, New Haven, November 11. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.; Eclectic, New Haven, November 11. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

FLORIDA: Jacksonville, November 12-13. Sec., Dr. J. D. Fernandez.

MAINE: City Hall, Portland, November 11-12. Sec., Dr. Frank W. Searle, 776 Congress St.

MASSACHUSETTS: Regular, State House, Boston, Nov. 11-13. Sec., Walter P. Bowers, Room 159, State House, Boston.

NEBRASKA: Lincoln, November 12-13. Sec., Dr. H. B. Cummins, Seward.

SOUTH CAROLINA: Columbia, November 11. Sec., Dr. A. Earle Boozer, 1806 Hampton St.

TEXAS: Bender Hotel, Houston, November 11-13. Sec., Dr. W. L. Crosthwait, Suite 1003, Amicable Bldg., Waco.

WEST VIRGINIA: Hotel Chancellor, Parkersburg, November 10. Sec., Dr. S. L. Jepson, Wheeling.

Colleges Adopt Higher Requirements

The new announcement of the University of Arkansas, Medical Department, indicates that after Jan. 1, 1914, that school will require for admission one year of collegiate work, including courses in physics, chemistry, biology and German or French, in addition to a standard four-year high-school education. The Medical College of South Carolina also announces the adoption of the same requirement after the beginning of the year. This makes seventy-nine colleges which either already are enforcing the entrance requirement of one or two years of collegiate work, or which, according to their announcements, will do so after Jan. 1, 1914.

Illinois June Report

Mr. Amos Sawyer, acting secretary of the Illinois State Board of Health, reports the written examination held at Chicago, June 17-19, 1913. The number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 285, of whom 258 passed and 27 failed. Two candidates withdrew and for five candidates the examination was incomplete. The following colleges were represented:

College	Year Grad.	Total No. Examined
PASSED		
Bennett Medical College	(1913)	14
Chicago College of Med. and Surg.	(1913)	102
Chicago Medical College	(1890)	1

* Official information from the college says this man is not a graduate.

The following questions were asked:

ANATOMY AND EMBRYOLOGY

1. Describe in detail the scapula. 2. What bones enter into the formation of the wrist joint? 3. Give origin and insertion of the biceps and triceps muscles. Give the origin and branches of the femoral artery. 5. Give origin, course and distribution of the vertebral arteries. 6. Describe the coverings of the brain. 7. Give the divisions of the spinal nerves and the number of each. 8. Name the anatomic divisions of the abdomen and describe the linea alba. 9. Describe the gall-bladder and name the bile ducts. 10. Describe the male urethra.

PHYSIOLOGY AND HISTOLOGY

1. Define a reflex action and name three reflexes of interest to the practitioner. 2. Give the general relations of the gray and white matter in the cord. How do we determine from what region any given section is taken? 3. Mention some important characteristics of the pulse in health and *disease*. 4. Give general description of the heart, defining its function. 5. Give the physiology of respiration. 6. Describe the pressure conditions in the *lungs and thorax and their* influence on the circulation. 7. Describe the digestion and absorption in the stomach. 8. What is urea and where found? 9. Give histological structure of the cornea. 10. Give the histology of the nasal mucous membrane.

BACTERIOLOGY AND HYGIENE

1. State the agencies by which the body protects itself against the entrance and bad *effects of pathogenic* bacteria. 2. State the products of bacteria. Give functions. 3. Define spirilla, bacilli. Illustrate. 4. N pathogenic diplococci. 5. Name the most comm ion in diphtheria. 6. State the chief sources of of drinking-water. 7. What precautions are *necessary* to insure healthy *sleep?* What gases accumulate in improperly ventilated sleeping-rooms? 8. How would you prepare an artificial food for a new-born infant? 9. Describe the effects of a cereal diet. 10. Give a proper diet in the case of diabetes mellitus.

CHEMISTRY AND MEDICAL JURISPRUDENCE

1. To what salts do most cathartic minerals owe their virtue? 2. What are *proteids?* Name one. 3. What pathologic conditions produce bile in urine? 4. Mention several tests for sugar. 5. Give chemical antidote for silver nitrate, mercury bichlorid, Tr. iodin. What is formed? 6. Define oxidation and where does it occur in the body? 7. How would you determine organic matter in water? 8. How do gunshot wounds differ from other wounds? 9. Give the distinguishing marks between ante-mortem and post-mortem wounds. 10. Differentiate between dementia and hysteria.

OBSTETRICS AND GYNECOLOGY

1. Give the dimensions of the female pelvis. 2. How would you treat a case of incomplete abortion? 3. Give the treatment of subinvolution of the uterus following labor. 4. Give the causes and treatment of puerperal septicemia. 5. Give some of the indications for version. How would you do it? 6. What is Credé's method of expelling the placenta? 7. Give the most common cause of pus tubes or pyosalpinx. 8. At what age does menstruation occur? Name some of the causes of delayed menstruation. 9. Name some of the causes of incontinence of urine in women. 10. Name the causes of dysmenorrhea and give treatment.

PRACTICE OF MEDICINE AND PEDIATRICS

1. In what cases would the ophthalmoscope aid in diagnosis? 2. Of what import is the spleen in the diagnosis of febrile conditions? Define splenic dulness. 3. Differentiate early pleurisy from intercostal neuralgia. 4. Make a diagnosis of aneurysm of the descending aorta. 5. Describe treatment of acute inflammatory articular rheumatism. 6. What diseases may cause occlusion of the common bile duct? 7. Differentiate the coma of opium poisoning from that of cerebral hemorrhage. 8. What treatment would you recommend for diphtheritic paralysis? 9. Give symptoms and treatment of whooping-cough. 10. Give symptoms, complications and *treatment of* mumps.

PRACTICE OF MEDICINE AND PEDIATRICS (ECLECTIC)

1. Give the etiology, diagnose and 2. Make diagnosis, outline treatment of diabetes mellitus. 3. Discuss acute ling common sequelae. Give treatment. iagnose and treat scarlet fever. 5. Give the symptoms, diagnose and treat *erysipelas.* 6. Define sciatica. Diagnose and treat. 7. Give the symptoms, diagnose and treat lobar pneumonia. 8. Diagnose and treat incipient pulmonary tuberculosis. 9. Define poliomyelitis. Diagnose and treat. 10. Define cerebrospinal meningitis. Diagnose and treat.

SPECIAL MEDICINE

1. Discuss heart murmurs. functional. 2. Define dyspnea. Discuss va 3. Diagnose and treat frontal sinus and treat diphtheria of the nasal passages. 5. Diagnose and treat tuberculosis of the larynx. 6. Discuss aphonia. 7. Define *diplopia*, ptosis. Give etiology, diagnose and treat. 8. Define glaucoma. Diagnose and treat. 9. Give the etiology, diagnose and treat *poliomyelitis.* 10. Give the etiology, diagnose and treat chorea.

SURGERY

1. Classify tumors and give the theories concerning their origin. 2. *Discuss the indications for drainage and describe* two drains in common use. 3. Give the *early* symptoms of *carcinoma of the* stomach and describe in detail one of the laboratory tests which is helpful in the diagnosis of the same. 4. Describe *ligation of the* middle meningeal artery near its point of bifurcation, including *the topography* on the exterior of the skull. 5. State the ways in which a fracture of the olecranon process is produced and give *its symptoms* and treatment. 6. Give the symptoms of the most common dislocation of the hip joint and *describe one* method of treatment by manipulation. 7. Describe in detail an amputation of a finger at the metacarpophalang Discuss the etiology of peritonitis. 9. *Give the* diagnosis and details of surgical treatme emoral hernia. 10. Define Fowler's position, sition, meningocele, *appendicectomy, choledochotomy,* talipes equino-valgus, aneurismal varix, *pylephlebitis,* ranula, *hypospadias.*

MATERIA MEDICA AND THERAPEUTICS

1. Convert liter, gram and c.c. into weights and measure ordinarily used in *U. S.* Army. 2. Write a *prescription* containing four *remedial agents.* 3. What is normal blood-pressure? Name two drugs that increase it. 4. *Enteroclysis; hypodermoclysis;* describe them. 5. Tr. nux vomica; give dose and per cent. of strychnia it contains. 6. *Iodin;* give therapy. 7. Air and sunshine; give

therapy. 8. Iron; give therapy. 9. Digestive ferments; name principal ones and give therapy. 10. Mineral acids; give therapy.

MATERIA MEDICA AND THERAPEUTICS (ECLECTIC)

1. Give properties, dose and specific indications for digitalis, belladonna and gelsemium. 2. What is the source of quinine? Give dose and therapy. 3. Give therapeutic indications and dose of arsenous acid. 4. What is oleoresin aspidium? Give dose and therapy. 5. Discuss the therapeutic value of diaphoresis. What drugs and measures are most effective? 6. Write a prescription useful in the treatment of acute cystitis. 7. Discuss therapeutic measures of value in the treatment of arteriosclerosis. 8. What remedies are useful in the treatment of angina pectoris? 9. What measures would you use for the relief of hyperpyrexia? 10. What is an antitoxin? Name two and give dose of each.

Book Notices

MIND AND HEALTH. With an Examination of Some Systems of Divine Healing. By Edward E. Weaver, Ph.D., with an Introduction by G. Stanley Hall, Ph.D., LL.D., President of Clark University. Cloth. Price, $2 net. Pp. 500. New York: The Macmillan Company, 1913.

The material contained in this volume was originally prepared for a thesis for the degree of Doctor of Philosophy at Clark University, but, according to the author, it has been greatly elaborated since that time. His own words best set forth the object of the book, "The study of the influence of mental states upon health has now entered upon the stage of exact investigation, by both psychology and medicine. This treatise is an attempt to embody some of the latest results of the psychologic study of this important subject and to lay down the fundamental psychological principles governing health and promoting healing. Inasmuch as there is a strong tendency on the part of religious bodies to make non-medical healing a part of their work, and because this is done without a thorough knowledge of psychology or medicine, there is urgent need for the examination of this professed healing."

The proposition which the writer has undertaken to demonstrate is that the treatment and cure of disease, or at least of a certain class of disease, is a proper function of religious organizations. Dr. G. Stanley Hall in the introduction says, "I see no reason why religion, which in past ages has always exerted such a profound influence on all matters of health and disease, cannot rehabilitate for itself from the material herein described its old function of healing, which, when it is complete, will have a profound significance on the future fate and function of the church."

With all possible sympathy for the author and his efforts, the impartial reader is forced to admit that the book falls short both of its possibilities and of the ambitions of the writer. It is apparent throughout that the writer, however conversant he may be with psychology, is not familiar with modern scientific medicine. This is shown in the quotation from the preface given above, in which is found the old and inaccurate distinction between medical and non-medical healing, the author apparently assuming that the field of modern medicine in the treatment of disease is limited to the use of drugs. The attitude of the author toward the instances of healing which he narrates is one of credulity rather than of scientific discrimination, while his apparent confidence in testimonials and *ex parte* statements shows a lack of appreciation of the relative value of evidence. It is also noteworthy that in citing authorities on psychotherapy he too often refers to the most demonstrative rather than to the most authoritative writers in this field. The reasoning in many cases is of the *post hoc, ergo propter hoc* variety, found in all sectarian literature. The cases referred to in the introduction are of the old familiar type. A woman is suddenly stricken with a mysterious malady. The physicians in the case "have given her up." The patient is said to be "entirely beyond the reach of medical science." These are the usual formulas for such cases. The healer or the minister or the aged father prays for her recovery. The woman recovers. Therefore, she was healed by prayer. It is hardly necessary to point out the many fallacies in this line of argument.

Mr. Weaver would have written a better book if he had confined his efforts to the history of the various mental-healing movements, on which subject he is clear, concise and interesting. But when he attempts to formulate general principles he gets into deep water. No one familiar with modern psychotherapy will agree with him that "the practical handling of psychotherapeutic principles runs precisely parallel to the terms of the gospel evangel, and to-day science is affording us the wondrous spectacle that in order to free ourselves of disease we must employ the same means that we have been led to employ in the past to become free from sin." The loose reasoning here is equaled only by its loose diction.

The principal "religious systems" considered are Christian Science, the Emmanuel movement, Dowieism, and metaphysical healing. If the author had gone more deeply into the history of medicine, and if he were familiar with the "miracles" which are a part of all religious and emotional movements, as well as such strange chapters in human experience as mesmerism, Perkins tractors, the earlier days of electricity, the belief in the miraculous power of kings and other exalted personages to cure diseases by the laying on of hands, he would realize that the phenomena which he regards as associated with religion are in fact to be found as an accompaniment of any popular movement or belief in which are found the elements of ignorance, credulity, superstition, mystery and compelling personality. He would also perhaps learn something of the value of human testimony and would discriminate more carefully as to his witnesses.

Mr. Weaver's book may be read with much profit by one desiring facts as to the different mental-healing sects. It is necessary, however, to discriminate carefully between the writer's statements of fact and his elaboration of theory. Its publication as a thesis by a fellow of Clark University and its introduction by Dr. G. Stanley Hall gives it a weight and an importance which makes careful criticism of its conclusions all the more necessary.

IRRITABILITY. A Physiologic Analysis of the General Effect of Stimuli in Living Substance. By Max Verworn, M.D., Ph.D., Professor at Bonn Physiological Institute. Cloth. Price, $3.50 net. Pp. 264, with 63 illustrations. New Haven: Yale University Press, 1913.

This volume comprises the eighth series of Silliman lectures, delivered at Yale University in 1911-1912. In this series of nine lectures the author endeavors to "show what information the analysis of irritability and of the effect of stimuli can give us of the nature of the processes in living substances." The historical development of the modern conception of irritability is outlined in the first lecture. Of special interest to the physician is the important contribution to the conception of irritability by Virchow in establishing the cell doctrine in pathology and medicine, with its corollary that "disease must be considered as a reaction of body-cells to stimuli." The subjects treated in the final chapter are the general effects of stimuli, the nature of the excitation processes, conduction of the excitation processes, the nature of fatigue, inhibition and narcosis.

Verworn is a recognized authority in the field of general physiology, and the volume is an interesting, and, on the whole, fairly complete digest of recent investigations in this field. It is but natural that he should give special prominence to work from his own laboratory and by his own pupils. Many scientists, however, will question his view that "the modern scientific conception of cause does not originate from experience, but is the remains of a part of the old anthropomorphic mysticism carried over into our own times" (page 20). Few physiologists will admit that Verworn makes out a strong case for his view that "fatigue is an extension of the refractory period." Yet the book will interest both the clinician and the laboratory man. Neurologists will be particularly interested in the evidence cited for the existence of the all-or-none law in nerve fibers; that is, that there is no such thing as nervous impulses of varying strengths in the same axis cylinder. If this contention of Gotch and of Verworn shall finally prove true we must greatly modify our present conception of the mechanism involved in weak and in strong voluntary movements in the same individual.

We are glad to be able to say that our leading American pathologists recognized long ago that "disease is life under altered vital conditions and altered vital conditions are stimuli —the pathologist who does not wish to confine his observations to purely superficial symptomatology must seek to penetrate into the nature of the general reactions to stimulation in living organisms. In this field we expect much from pathologic *investigation, which* alone has abundant material at its command. But this will take place only when pathology adds to the histologic direction of the investigation that of experimental physiology" (page 72).

ABWEHRFERMENTE DES TIERISCHEN ORGANISMUS GEGEN KÖRPER,- BLUTPLASMA- UND ZELLENFREMDE STOFFE, IHR NACHWEIS UND IHRE DIAGNOSTISCHE BEDEUTUNG ZUR PRÜFUNG DER FUNKTION DER EINZELNEN ORGANE. Von Emil Abderhalden, Direktor des Physiologischen Institutes der Universität zu Halle a.S. Second Edition. Paper. Price, 5.60 marks. Pp. 199, with 12 illustrations. Berlin: Julius Springer, 1913.

This is the second edition of the *monograph* issued a short time ago under the title of "Schutzfermente," the new title *being selected in deference to the fact that* the defensive action of the *enzymes concerned* in reaction to foreign substances does not invariably lead to a complete protection, as might be implied by the title "Schutzfermente." The value of this monograph lies in the fact that it represents a study of the fundamental processes of immunity from the standpoint of a *progressive*, biological chemist. As *nearly all the work* that has been done in this field, which is *essentially* chemical, has been accomplished by bacteriologists and pathologists who have had but slight appreciation of the *chemical* aspects of their work, it is not strange that a *chemist* finds many possibilities which his predecessors have overlooked. Professor Abderhalden is unusually gifted in his *presentation* of scientific work to general readers, and this book, like all his other writings, is interesting reading. The medical man who wishes to keep in touch with the *advances* of immunity will find profit and pleasure in Professor Abderhalden's latest summary of his work and ideas in this field.

IONIC MEDICATION. The Principles of the Method and an Account of Clinical Results Obtained. By H. Lewis Jones, M.D., Consulting Medical Officer to Electrical Department in St. Bartholomew's Hospital. Cloth. Price, $1.50 *net*. *Pp.* 151. Philadelphia: P. Blakiston's Son & Co., 1913.

This little book gives an *unexaggerated, scientific* statement of the principles and of the practice of ionic medication, and, unlike so many books, *it has a* reason for existence, for it is practically the only book on the subject. Ionic medication has a field of usefulness and the book is recommended as worthy of study.

HYSTERIE. Zur Frage über die Entstehung hysterischer Symptome. Von Dr. J. M. Raimist, Leiter der Nervenabteilung des Jüdischen Hospitals in Odessa. Paper. 3.50 marks. Pp. 101. Berlin: S. Karger, 1913.

This is a dissertation on the origin of hysteric symptoms, based on a few cases as observed by the author. No new message will be found here, but a reiteration of what many have long contended, namely, that hysteria is an emotional disorder causing physical symptoms. That *symptoms often* disappear when the patient's attention is diverted from his malady has also been known for ages.

UEBER HALLUZINOSEN DER SYPHILITIKER. Von Privatdozent Dr. Felix Plaut, Wissenschaftlichem Assistenten der Psychiatrischen Universitätsklinik in München. Paper. *Price* 5.60 marks. Pp. 116. *Berlin: Julius* Springer, 1913.

In this interesting monograph the author makes an attempt to differentiate a certain type of hallucinatory psychosis occurring in syphilis of the nervous system from general paresis and the tabetic psychoses. He makes use of the new laboratory aids (1) Wassermann in blood, (2) Wassermann in cerebrospinal fluid with *increasing quantities*, according to Nonne-Hauptmann, (3) lymphocyte count, and (4) Nonne's globulin test. Having observed clinically, over long periods of time, cases that gave positive laboratory reactions of syphilis of the nervous system, but not the clinical signs of general paresis, tabetic psychosis or alcoholic paranoia, he concluded that the mental disturbances, chiefly of a hallucinatory character, belong to syphilis proper. He cautiously advances the view that such hallucinatory disturbances might be caused by the syphilitic poison in the same way as the gross physical lesions. The monograph is very suggestive; the histories are complete and the conclusions quite conservative. Perhaps one of the most instructive portions of the book is that in which the new laboratory aids in the diagnosis of brain syphilis are discussed.

Medicolegal

Manslaughter Is Such Neglect of Infant as to Cause Its Death —Duty of Poor Person as to Procuring Medical Aid for Child or Stepchild

(Stehr vs. State (Neb.), 139 N. W. R. 676)

The Supreme Court of Nebraska affirms a conviction of the defendant Stehr of manslaughter by negligently causing the death of his stepson, a child about 4 years of age, for which he *was* sentenced to the penitentiary for a term of from one to *ten years*. The court says that it appeared that the child, called "Kaurt," was to some extent *afflicted* with bed-wetting; that one very cold night, after a day of "blizzard," the defendant *allowed the fire to go out altogether*, although he had a small supply of coal; and, sometime during the night, he discovered that Kaurt had wet the bed; that the bedding was frozen stiff, and that the room was full of frost; that snow had drifted through the crack of the door, and through a broken window-pane, and the bedding on all of their beds was frozen stiff. Notwithstanding this *situation, the defendant* built no fire, and, as stated by him, he turned the bed-tick over on which Kaurt slept, and again placed the child in the bed alone, where he lay until the next morning. Shortly after this, and as early as the fifth day *following*, it was discovered that the child's feet had been frozen, and had begun to show signs of discoloration. Mrs. Stehr stated that the child's feet looked gray and somewhat green in spots. The defendant thereupon applied hot water and dressed the feet with cloths saturated with *petrolatum*. No physician was consulted or called until the sixteenth day after the freezing, at which time the child's feet were so badly decomposed that the stench arising *therefrom* had become unbearable. The defendant's wife then went to a merchant, with whom *they were trading*, and inquired for a German *doctor*. One was recommended, and he called to see the *child, but declined* the case because the defendant had *no money*. *Another* German physician was called, *who on* the same evening visited the child and also declined the case, but recommended that the city physician be notified of the situation. On the *following* day the city physician, who was a skilful surgeon, called *at the defendant's* house, examined the child, found a gangrenous condition of its feet, and informed the defendant that amputation was absolutely necessary. Meanwhile one of the county commissioners, who was active in securing assistance for the poor, furnished *the defendant with a supply of coal and other* necessaries, and arranged for the amputation. The child was taken to the home of a *professional* nurse, and on the following day the operation was performed and everything possible was done for the relief of the child. It was found, however, that sepsis or blood-poisoning had developed to such an alarming extent that a recovery was *impossible*, and on the twenty-second day after the freezing the child died.

The court says that it must be observed that the question actually submitted to the jury was whether or not the defendant was criminally negligent in failing to provide medical care for his stepson after he discovered the frozen condition of the child's feet. It was contended that the defendant was an ignorant German, unable to speak *the language* of this country, was without means to procure medical assistance, and therefore was not responsible for his neglect. The evidence showed, however, that he was a fairly intelligent man: that he was surrounded by his friends and neighbors, all of whom could speak both German and English; that he failed *to mention the child's* condition, or inform them of his necessities. His own testimony showed that for ten or eleven days he saw the child's feet turn from gray to purple, from blue to green and black, and saw its flesh rotting and dropping away, yet made no effort to procure medical aid until the odor of the rotting flesh became unbearable. It seems idle to assert that he was so ignorant as not to realize the necessity for calling a physician.

The degree of negligence in such a case that would make a man criminally responsible can hardly be defined. It is not a slight failure in duty that would render him criminally negligent; but a great failure of duty undoubtedly would. The line between the two extremes is hard to define, and is a question that must be left to a great extent in each individual case to the common sense of the trial jury. It is for them to determine whether or not the degree of failure of duty is in fact criminal. As the court views the evidence, the jury had a sufficient basis for finding the defendant guilty of such criminal negligence as would amount to manslaughter.

The defendant was charged with the legal duty of seeing to it that the child's life was not endangered. If he realized the condition of the boy's feet and for ten days failed to call a physician, or if he negligently refused to ascertain the condition of the boy's feet in time to call a physician, then the jury would be justified in finding him guilty of criminal negligence.

For a parent having special charge of an infant child so culpably to neglect it that death ensues as a consequence of such neglect is manslaughter, although death or grievous bodily harm was not intended. If the parent has not the means for the child's nurture, it is his duty to apply to the public authorities for relief, and failure to do so is itself culpable neglect, wherever there are public authorities capable of affording such relief.

Exclusion of Milk from City—Health Officer Not Liable—Power of Department of Health

(Bellows vs. Raynor (N. Y.), 101 N. E. R. 181)

The Court of Appeals of New York affirms a judgment dismissing the complaint in this case, brought by the plaintiff, who was engaged in dairy farming, to recover damages from the defendant, chief of the division of general sanitary inspection of the department of health of the city of New York, for having, as the plaintiff alleged, trespassed on his property rights. The plaintiff complained that the defendant had unlawfully and wrongfully stopped the delivery of the plaintiff's milk product to a creamery, ordering and directing the creamery company not to receive the milk. The court thinks that the plaintiff was properly nonsuited, for, if the plaintiff's complaint was in trespass, the evidence failed to show an unauthorized entry on his premises, either by the defendant, or by any agent. If, however, the alleged "trespass on the property rights of the plaintiff" consisted in causing the interruption in the sale of his milk product, then no cause of action was made out. If what the plaintiff intended was to charge an illegal exercise by the defendant of official power, or of the powers conferred on the board of health, no cause of action was established. The complaint did not allege that the defendant acted in excess of his authority as an officer of the department of health, nor that he acted in bad faith, or without due care, or maliciously, and therefore, in what he did as such officer, he was protected by the statute against the consequences. Acting as an officer of the department of health, in good faith, if the defendant's acts caused any loss to the plaintiff, the latter's exclusive remedy, on the ground of an illegal exercise of power, was by an action against the city.

The argument that the department of health of the city of New York exceeded its lawful powers "in assuming to regulate the method of the production of milk by the plaintiff, and in prohibiting the creamery company from including plaintiff's milk in its shipments," was unsound, as was the argument that the statute, if conferring such an authority, was invalid as delegating to the officers of the municipality jurisdiction over the affairs of another locality. The department of health of the city of New York is charged by law with the responsibility of preventing pestilence and disease in the city of New York. Its duty is to enforce all laws applicable to the preservation of human life and the promotion of health, and such as relate to the use or sale of unwholesome, deleterious or adulterated food. In the faithful and efficient performance of that duty, the whole state, as well as the city, is concerned, and the department must be deemed to possess whatever power is needed to make effective the express powers conferred. So broad is the responsibility with which the department of health is charged that it is to give all information in its possession, relating to the existence and cause of disease, to the local health authorities of any city, village, or town, which may request the same, and to "add thereto such useful suggestions" as experience may supply.

Of the food supplies introduced into the city of New York, milk is one of the most important. It is now a matter of common knowledge that, if infected, it carries with it the germs, or bacilli, of dangerous and epidemic diseases. It is the food of the infant, and it is an important element of the food of the adult. It may be infected as it comes from the cow, or it may be contaminated by reason of the insanitary conditions of the dairy. Whatever, therefore, the department of health may do toward preventing the introduction of milk into the city of New York, which its officers have reason to believe to be unwholesome and deleterious, is in the performance of a statutory duty.

It is unreasonable to say that the department of health, in exercising such a power, renders itself amenable to the charge of exercising an extraterritorial jurisdiction. In notifying the creamery company not to include the plaintiff's milk in its shipments to the city, it was acting for the protection of the inhabitants of the city of New York, and therefore for local interests. There was no interference with the plaintiff's conduct of his farm or business, except as he proposed to supply milk to the city of New York; there was simply an embargo laid on the introduction, within the city of New York, of any milk not produced by him under conditions specified by the department. It had the right to exact from all shippers of milk a compliance with such conditions as would reasonably tend to a pure product for the use of the citizens as a condition of permitting its sale in the city of New York.

Contract Not to Practice in Vicinity After Dissolution of Partnership Binding

(Glover vs. Shirley (Mo.), 155 S. W. R. 878)

The Kansas City Court of Appeals reverses a judgment rendered for the defendant in this action to enjoin him from the practice of medicine anywhere within a radius of 10 miles of a named town, directing that a decree be entered for the plaintiff restraining the defendant as prayed in the petition, and for normal damages. The court says that the plaintiff was an established physician in said town, and desired the assistance of a younger man. After some preliminary talk at different times, he and the defendant, also a physician, entered into a written contract which stated that they had entered into a partnership for the general practice of medicine and surgery at said place, and surrounding territory, said partnership to continue so long as mutually satisfactory and agreeable to both parties, and to be terminable at the will of either, said parties to share equally the expenses and the profits of the partnership, and, in the event of the partnership being, for any reason, dissolved, the defendant agreed not to practice medicine or surgery, for a period of ten years, either by himself or as a member of a partnership, in said town, or within a radius of 10 miles from said point.

At the expiration of several months this contract was dissolved, and their partnership accounts settled between them. The defendant then located himself in the town, and began the practice of medicine, and the plaintiff, as already said, brought this action to restrain him. The law justifies such action. "That contracts restraining the exercise of a trade or profession in particular localities are valid, when there is fair and reasonable ground for the restriction, as in the case of the sale of the good will of a trade or business, where the vendor covenants not to pursue the same business within certain limits, is beyond question." McClurg's Appeal, 58 Pa. 51. In *Gordon vs. Mansfield*, 84 Mo. App. 367, Smith, P. J., speaking for this court, made the observation that: "The doctrine had been at rest ever since Lord Kenyon declared in *Davis vs. Mason*, 5 T. R. 118, in which the bond of a surgeon not to practice within 10 miles of the place where the obligee lived was held good." And he further quoted Judge Scott's remark in *Presbury vs. Fisher*, 18 Mo. 50, that: "There is no practical man who would not smile at the conceit that the public welfare would sustain an injury by enforcing an obligation" which would prevent one from exercising a certain business in certain limits for a limited period.

There was no lack of consideration for the contract. The mutual obligations of a contract stand as a consideration for each other. It is proper to assume that the plaintiff would not have entered into the contract at all without incorporating the agreement not to practice in the named town.

Nor does it appear to the court that the mere failure to seek out the defendant and tell him he ought not to do what he agreed he would not do was sufficient to nullify the contract.

Laymen Mistaking Apoplexy for Drunkenness

(Middleton vs. Whitridge (N. Y.), 141 N. Y. Supp. 104)

The First Appellate Division of the Supreme Court of New York reverses a judgment rendered in favor of the plaintiff, as administratrix, against the defendant, as receiver of the Third Avenue Railroad Company, for damages for the death of one Lewis Middleton, a man aged 51, who had boarded a street-car, being kept on the car for five hours under the supposition that he was drunk, when, after he was finally taken to a hospital, his trouble was diagnosed as cerebral hemorrhage. The court says that it was conceded that the defendant was in no way responsible for the cerebral hemorrhage or stroke of apoplexy. It happened while Mr. Middleton was on the car, not because he was there; or on account of anything which occurred while there. The actionable negligence claimed, on which alone the judgment reversed rested, was the failure of the conductors, motormen, and starters of the street railroad company to properly diagnose his condition and promptly procure for him medical treatment and complete rest. The claim was that this neglect aggravated the condition, and accelerated the death, which might not otherwise have happened. This led to two inquiries. 1. Was there actionable negligence? 2. Was such alleged negligence the proximate cause of death?

While it is shocking to think that a man stricken with apoplexy should be carried around the city for five hours in an open street car, the question was: Did it follow that the defendant was responsible in money damages? It is established that, so far as external appearances are concerned, it is difficult to differentiate between intoxication and apoplexy. Even medical men and hospital officials make mistakes. Was it negligence, then, for the two motormen, two conductors, two starters, and an inspector to conclude that the man was under the influence of liquor, and not to discover that he had a stroke of apoplexy? It must be taken into consideration, also, that a policeman and two passengers came to the same conclusion, and that no passenger during all those five hours made any suggestion to the employees that the man was sick, rather than as he appeared.

The treatment by these employees of this unfortunate passenger, instead of being susceptible to the charge of gross brutality and inhumanity, seemed to have been actuated by a kindly and sympathetic feeling. Instead of being thrown off the car, he was allowed to remain where he had put himself, with the notion that it was the best thing for him; that he would sleep it off, and that he had better be in the open air.

No case holds a street railroad employee to the duty of correct medical diagnosis, and, when nothing is done to interfere with the passenger, holds the company responsible for an omission to call a physician or transport him to a hospital. The court thinks that actionable negligence was not made out.

It does not seem that the responsibility for this death was traced to the defendant with that degree of certainty which the law requires. It was not responsible for the cerebral hemorrhage. It was really but guesswork to say that prompt attention would have saved the life. The defendant's liability as the proximate cause of death was not satisfactorily established. Therefore, on both grounds, the plaintiff failed to make out a cause of action.

Fourteenth annual meeting, held in Boston, Oct. 1-4, 1913

(Continued from page 1659)

SYMPOSIUM ON BONE DISEASES

Unusual Bone Lesions

Dr. A. Hartung, Chicago: I have seen three cases of osteitis fibrosa, two of them being of the deformans type, or Paget's disease. The roentgenogram is characteristic, showing a chronic inflammatory condition of the bony skeleton associated with a softening and overgrowth leading to deformities which are almost pathognomonic. There is a marked bowing and enlargement of the long bones, and hyperostosis and thickening of the flat bones. There is a coincident porosis and sclerosis, with areas resembling cyst formation. I have also seen a case of multiple bone cysts or osteitis fibrosa cysticus —von Recklinghausen's disease. These lesions are primary in the bone. Another type of bone lesion which is secondary to disease elsewhere in the body is hypertrophic osteoarthropathy of Marie. I have seen three cases of this type. There was a marked osteoperiostitis involving particularly the metacarpals and metatarsals. I cite these cases particularly to emphasize the fact that the roentgenogram furnishes an absolute means of diagnosis.

Chronic Typhoid Periostitis

Mr. H. W. Dachtler, Toledo, Ohio: There is such a condition as a typical typhoid periostitis and osteitis, which occurs late in the attack, or during convalescence. The periosteal inflammation is the most common; multiple lesions are frequent; bilateral involvement is not uncommon; the tibia is the bone most frequently involved. The bone changes are characterized not so much by the type of infection as by its virulence, and the condition may be confused with a syphilitic lesion unless the clinical history of the case is gone into carefully.

Roentgen Diagnosis of Bone Diseases

Dr. W. C. Hill, Cleveland: Roentgenoscopy is of particular value as a method of differential diagnosis in the various types of arthritis, exostoses, bone cysts, sarcoma, carcinoma, enchondroma, osteomyelitis, tuberculosis, syphilis and Charcot's disease. The roentgenogram is so characteristic as to be pathognomonic. Atrophic arthritis is characterized by atrophy of the articular cartilages and erosion of the bones; hypertrophic arthritis, by thickening and lipping of the articular surfaces. Usually there is a small hook on the patella when the knee is involved, and it is the joint most often involved. In infectious arthritis there is a slight rarefication of the bone, with sometimes marked destruction of the articular surfaces. Sarcoma gives a fuzzy appearance and when it breaks through the periosteum the surrounding soft tissues are seen to be involved. This is characteristic of sarcoma—the numerous lamellae and straggling filaments of bone. At a still later stage the entire bone becomes destroyed. Carcinoma produces a crater-like depression in the bone, the walls of which have a gnawed appearance. The surrounding bone appears absolutely normal. Bone cysts present a transparent cavity in the bone. They destroy the medulla, but never break through the cortex. In bone abscesses there is a surrounding envelope of ossifying periostitis, or eburnized bone.

Bone Syphilis

Dr. Percy Brown, Boston: The fusiform subperiosteal overgrowths, usually near the joint, are the most common findings in bone syphilis. Sometimes the so-called Codman "blister" is seen. It represents a small area in the bone in which the infection seems to be particularly severe, and the periosteum overlying it seems to be elevated or raised from the bone. I have called this the "pudding-stone" type of periosteal hyperplasia.

DISCUSSION ON SYMPOSIUM

Dr. P. M. Hickey, Detroit: We must guard against making a diagnosis of syphilis because the lesion might be one of the others mentioned. On the other hand, we should look for syphilitic bone manifestations, especially in obscure cases. We should not, however, base a diagnosis on the roentgenogram alone, unless we are absolutely sure of our ground. The stereoscopic method is the preferable one.

Dr. J. H. Edmonson, Birmingham, Ala.: I have found syphilitic bone disease when three Wassermann tests were negative. Antispecific treatment, potassium iodid and mercury, effected a cure.

Dr. F. H. Baetjer, Baltimore: The situation of the lesion will frequently help us. Carcinoma practically always starts in the bone where the nutrient artery enters. If the growth is elsewhere in the bone one can rule out carcinoma. In the non-malignant growths there is production of new bone, and it is symmetrical. The cortex is thinned out but intact. In the malignant growths the bone is destroyed, even the cortex. The non-malignant growths do not infiltrate the surrounding tissues, whereas the malignant growths do infiltrate. It is difficult to make a positive diagnosis of syphilis unless one or more bones are involved.

Fracture of Skull with Air in Ventricles

Dr. William H. Stewart, New York: A man sustained a fracture of the frontal bone in the region of the outer edge of the right frontal sinus. Later he had severe headaches, with occasional vomiting, and he became dull and listless. The neurologic diagnosis made at this time was "increased intracranial pressure, probably abscess." The ophthalmoscopic examination indicated a bilateral optic neuritis, also indicative of intracranial pressure. The leukocyte count was 15,900. The roentgenogram showed a dark circular shadow just back of the fracture. From the shape, location and course of this shadow, corresponding with the cerebral ventricles, the diagnosis of air in the cerebral ventricles was made. A needle was passed into the anterior horn of the lateral ventricle, and two or three quick spurts of air came from the needle when the obturator was removed. The patient died. It was subsequently learned that a severe pain in the head with a free discharge of fluid from the nose followed a violent blowing of the nose. The patient evidently established a communication between the nose through the right frontal sinus and anterior lobe of the brain into the right lateral ventricle, so that when he blew his nose he also inflated his cerebral ventricles.

DISCUSSION

Dr. Geo. E. Pfahler, Philadelphia: Dr. Pancoast and I had a patient referred to us who had become delirious apparently without cause. We roentgenoscoped the head and found an area of transparency in the left frontal region. We interpreted it at the time as a possible softening of the bone due to pressure. The patient got well in about six weeks, and further roentgenographic examinations failed to show this area. The history suggested sinus disease, but the sinuses were normal. We believe now that this was a case of air in the left ventricle.

Roentgenoscopy of Mediastinum

Dr. George F. Thomas, Cleveland: The symptoms that indicate mediastinal investigation are: (1) a feeling of oppression or sense of weight on the chest; (2) dyspnea; (3) dysphagia; (4) pain in mediastinum region possibly radiating to shoulders, arms, side of chest or upper abdomen; (5) tickling in throat, cough or desire to cough; (6) aphonia or hoarseness due to complete or partial paralysis of vocal cords; (7) enlargement of veins of face and neck; (8) unilateral flushing of face or unilateral dilatation of pupils; (9) tachycardia or bradycardia. The clinical history and physical examination may make the diagnosis. Roentgenoscopy always aids in doing so and may afford the only means for diagnosis. The position and shape of the mediastinum, the relation of the heart and great vessels, and anomalous shadows in the mediastinum are the points to bear in mind in making an interpretation of the roentgenogram.

DISCUSSION

Dr. George E. Pfahler, Philadelphia: There is danger of diagnosing beginning aneurysm in cases in which there is a projecting shadow in the region of the descending arch. In a case of that kind there was simply a tortuosity of the aorta causing clinical symptoms of aneurysm. This was confirmed at the necropsy. A fluoroscopic examination is of great value in these cases.

Dr. A. Howard Pirie, Montreal: Examining a patient with the fluoroscope and rotating him gives a stereoscopic effect on the screen, which is very valuable in an examination for aortic aneurysm.

Dr. William H. Stewart, New York: A dilated esophagus may cause mediastinum trouble and that may occur in case of carcinoma at the cardia. Cardiospasm must also be considered; likewise diverticulum.

Dr. F. H. Baetjer, Baltimore: Cardiospasm is closely associated with the position of the stomach. In every case of cardiospasm that I have seen there has been a distinct marked prolapse of the stomach.

Dr. L. T. LeWald, New York: I saw two cases recently in which there was marked prolapse of the stomach in conjunction with cardiospasm. In six cases I have seen a transposition of the heart, three within the past year.

Dr. Kennon Dunham, Cincinnati: The trachea is a landmark in all chest work. Its position will often help us to make a diagnosis.

Therapeutic Pneumothorax

Dr. Kennon Dunham, Cincinnati: I have made stereoscopic roentgenograms for the purpose of mapping out the extent and location of an artificial pneumothorax, and have found that they are far more reliable and accurate than the results of a physical examination. One can see the cavities becoming obliterated by successive injections of gas, and the position of the heart may be determined accurately. Therapeutic pneumothorax is a routine procedure in the Cincinnati Tuberculosis Hospital, but it is always safeguarded by stereoroentgenograms.

DISCUSSION

Dr. F. H. Baetjer, Baltimore: The great difficulty we have to contend with in producing artificial pneumothorax is pleural adhesions, so that in some cases it was almost impossible to get the lung sufficiently collapsed to be of permanent value. As to the formation of a hydropneumothorax, patients, as a rule, suffer little discomfort unless the fluid is excessive in amount.

Dr. L. T. LeWald, New York: Can you tell beforehand from the Roentgen findings whether or not it is going to be difficult to produce a pneumothorax?

Dr. Kennon Dunham, Cincinnati: Overfilling the pleural cavity is not only detrimental to the progress of the case, but dangerous to the life of the patient. There are two ways to judge that—by the clinical symptoms and by the roentgenogram. When there are no pleural adhesions there should be no difficulty. When they are present the gas will not flow in readily and only in limited amount. The accumulation of fluid is an important matter. I have not had it occur in my work until last August, when I saw two cases. The amount is usually slight and the roentgenogram will tell you whether it is of any significance. I have not been able to tell beforehand whether we could inject the gas or not. In four of our twenty cases we could not find any pleural space—and we tried many times and at intervals.

Roentgenotherapy of Raynaud's Disease

Dr. W. S. Newcomet, Philadelphia: I have had three cases of Raynaud's disease, in which roentgenization of the fingers was productive of good results. In the first case the tips of the fingers had ulcerated. Roentgenization was employed for a period of six months. The ulcers healed and the patient has since been free from pain. The ulcers have not recurred. The remaining two cases were similar to this one. The dosage in these cases was extremely mild, and the patients suffered discomfort and no sequelae.

Roentgen Diagnosis of Membranous Pericolitis

Dr. George H. Stover, Denver: In nine cases I have been able to diagnose roentgenographically a membranous pericolitis, the diagnosis being confirmed by operation. The picture seen was that of a malposition and deformity of the cecum, at times attended by more or less obstruction at the ileocecal junction, the latter also being characteristic of chronic appendicitis. The cecum does not change its position much through a series of plates. It is pulled inward from its usual position and is bent into the form of an arc with the convexity toward the right side of the body.

DISCUSSION

Dr. A. Hartung, Chicago: It might be possible to determine whether or not adhesions were binding the ascending colon to the transverse colon by changing the position of the patient.

Dr. George H. Stover, Denver: My patients were standing when the roentgenograms were made. I have also found that when there is a chronic irritation produced by an appendicitis, there is a lagging of the food in the terminal ileum—not due to an obstruction.

Roentgenoscopy in Diagnosis of Heart Lesions

Dr. W. J. Dodd and Dr. George C. Shattuck, Boston: In a series of cases the size and location of the heart and the lung margins by percussion was checked up by roentgenoscopy, and it was found that the former was far from being accurate; in fact, in none of the cases was it possible by physical means to make an accurate location. The roentgenogram showed that percussion had erred considerably, sometimes to the extent of an inch, in outlining the exact position of these viscera. The physical examination was made first and wires fastened to the chest wall to indicate the findings. Then the roentgenogram was made.

SYMPOSIUM ON GASTRO-INTESTINAL DISEASES

Roentgenoscopy of the Stomach

Dr. Lewis Gregory Cole, New York: I consider all localized areas of induration in the wall of the stomach, particularly those protruding into the lumen, as malignant. Serial roentgenograms are essential to a correct diagnosis. Small annular carcinomas that have not been recognized by fluoroscopy or single roentgenograms have been detected by a series of roentgenograms. A normal gastric secretion should not contra-indicate a thorough roentgenoscopy. Postpyloric ulcer is characterized by a constant deformity of the cap or pyloric sphincter caused by the induration or cicatricial contraction around the crater of an ulcer. In some instances the ulcer is viewed in profile; its indurated edges project into the intestinal lumen, and its crater is filled with bismuth. The puckering from cicatricial contraction may cause a deformity equally as great as the induration. Frequently, in addition to the deformity of the cap, there is a band of adhesion passing over on the gastric side of the sphincter, distorting the contour of the extreme pyloric end of the stomach. Not every deformity of the cap, however, is necessarily a postpyloric (duodenal) ulcer; it may be a spasm.

Roentgen Diagnosis of Duodenal Ulcer

Dr. Arial W. George, Boston: The exact method of diagnosing duodenal ulcer roentgenographically consists in demonstrating adequately the anatomic condition of the first portion of the duodenum. Ninety-five per cent. of duodenal ulcers occur in the first portion of the duodenum, and anatomically this part of the duodenum is a constant entity. It can always be demonstrated on the roentgenogram. A constant defect in the duodenal cap means a pathologic condition, such as ulcer, adhesions, cholecystitis, pressure of adjacent organs, and so forth. Any duodenal ulcer which is more than a simple mucous membrane erosion will deform the outline of the bismuth mass. A normal duodenal cap rules out indurated or surgical duodenal ulcer. We have been able to make a positive or absolute negative diagnosis.

The Stomach as a Reflex Organ

Dr. A. W. Crane, Kalamazoo, Mich.: The reactions of the stomach to reflex influences from without are manifested by cardiospasm, pylorospasm, hour-glass contraction, increased and decreased peristalsis, change in outline or position of pyloric antrum, and alterations in the character and quantity of the gastric juice. Gastric ulcer and duodenal ulcer are natural sequences. Roentgenologists must be careful to differentiate between true organic disease of the stomach and disease located outside of the stomach, manifested reflexly. Reflex stomach disturbances continued long enough finally give rise to actual organic stomach disease.

Indications Afforded by Roentgenoscopy For and Against Operations on the Stomach

Dr. A. Howard Pirie, Montreal: Chronic gastric ulcer, hour-glass stomach, gastric carcinoma, pyloric stenosis, caused by duodenal ulcer or carcinoma, gastroptosis, tumors pressing on and distorting the stomach, foreign bodies in the stomach and stenosis of the cardiac opening can definitely be recognized roentgenographically. Each condition gives a characteristic appearance on the roentgenogram. With reference to gastro-enterostomy, I examined about a dozen dogs and cats on which experimental gastro-enterostomy had been done. I found that when the operation was performed without closing the pylorus it was not a success; that it was a success when the pylorus was closed and the new opening was made near the pylorus; that it was not a success when the pylorus was closed and the new opening was in the cardiac end of the stomach. The rate of exit of food through a gastro-enterostomy opening is variable. It may pour through the stomach, so that gastric digestion is impossible. When the opening is at a considerable distance from the pylorus, residual food remains in the stomach between the pylorus and the opening. The indented appearance of carcinoma is so characteristic that one should be able to find it in very early cases. When barium remains more than six hours in the stomach, it is usually due to pyloric obstruction. Stenosis caused by carcinoma is usually evidenced by characteristic, finger-like indentations. When due to duodenal ulcer, typical changes are noted in the first part of the duodenum. Adhesions affecting the stomach can be recognized directly and indirectly. The normal stomach may show certain anomalies against which we must be on guard. Besides finding indications for and against operation by means of roentgenoscopy, we are at times justified in recommending medical treatment.

Discussion on Gastro-Intestinal Diseases

Dr. James T. Case, Battle Creek, Mich.: These patients should be examined with the fluoroscope as well as with the roentgenograph. The duodenal cap can be shown fluoroscopically in a great majority of cases. Its mobility during inspiration and expiration can be shown, and its relation to the definite pain point on pressure can be ascertained in a large number of cases. I have seen the appendix fluoroscopically in over three hundred individuals. I have also seen the appendix of this number of individuals in the roentgenogram.

The structures in the pyloroduodenal region can also be shown. I have seen a number of cases of hour-glass stomach due to penetrating ulcer on the lesser curvature, when the patient had had a gastro-enterostomy.

DR. GEORGE H. STOVER, Denver: Surgeons often fail to confirm our diagnosis because their fingers cannot feel what the roentgenogram shows. I have found in a number of cases that a chronic appendicitis will produce a spasm of the stomach.

DR. F. B. BAETJER, Baltimore: When the bismuth meal or food strikes the ulcer in the stomach or duodenum, it sets up contractions or peristaltic waves. The pylorus closes and the stomach contents are retained in that viscus. In the duodenum the same thing takes place, with the exception that there is not the spastic condition of the pylorus. I mean recent ulcers with no obstructive lesions. When the bismuth passes the pylorus and strikes the ulcer in the duodenum the irritation is set up, and there is a hypermotility of the duodenum, with rapid evacuation of its contents.

DR. ARTHUR F. HOLDING, New York: Serial roentgenograms are expensive, but the method is accurate, more so than fluoroscopy, because the sensitized plate is more sensitive to impressions than the retina of the eye. Objection has been raised to the expense of this method. In many cases a diagnosis cannot be made in any other way.

DR. GEORGE C. JOHNSTON, Pittsburgh: The combined method is the one that eventually will enjoy the most repute. We ought to be able to make a diagnosis of ulcer before the ulcer is formed, that is, when there is merely an irritation of the mucosa which gives rise to a change in the physiologic cycle of the stomach. This condition can be recognized with the fluoroscope.

DR. A. HARTUNG, Chicago: I had a case in which the roentgenograms showed a well-marked stenosis of the pylorus. The surgeon operated, but found nothing on macroscopic examination or palpation of the external wall of the stomach. He opened the stomach and then saw a benign annular growth near the pylorus. He did a gastro-enterostomy and the patient recovered.

2. Ulcer of Stomach and Duodenum.—Twenty patients were first studied clinically by Friedenwald, and then without any note being given as to the nature of the disorder, were referred to Baetjer for Roentgen examinations. The two reports were then placed side by side, and the clinical and Roentgen diagnoses corresponded so closely in every instance as to make the results appear most striking. The authors' general conclusions in reference to duodenal ulcer are these: There is excessive hypermotility of the stomach, with rapid emptying of contents, so that the greater portion of the stomach contents is emptied within the first half hour, the stomach contraction being practically normal and there is no evidence of hour-glass formation. There is hypermotility of the duodenum, with formation of a vacant area which remains fixed in all the examinations. The presence of a duodenal ulcer in simple cases uncomplicated by adhesions can practically always be determined. In gastric ulcer the question of the normal motility of the stomach is still open to debate, as evidenced by the fact that various authorities have given from two to six hours as being a normal period for expulsion of the bismuth contents.

At present it seems to Friedenwald and Baetjer that the gastric ulcer can be diagnosticated in certain situations only. From the roentgenographic standpoint one is able to see practically only one surface of the stomach and a portion of the greater and lesser curvatures. Should the ulcer be situated on the posterior surface of the stomach near the lesser curvature, it is not visible because the bismuth contents of the stomach completely obscures that side; consequently we are unable to see any alterations or irregularities of the peristaltic waves. It is only when the lesion is situated on the anterior surface of the stomach, and along the anterior surface of the lesser and greater curvature, that we can come to any conclusion. If the lesion is on the lesser curvature close to the pylorus, by making repeated examinations of the stomach we are able to see irregularities in the peristaltic waves, due to the induration and partial fixation of the ulcer. The diagnosis between gastric and duodenal ulcer from clinical signs alone is often very difficult, and many clinicians consider it impossible in many instances to differentiate between the two. The roentgenoscopic findings of the two conditions differ, however, so markedly that this method affords an almost positive means of differentiation.

3. Present Situation in Syphilis.—Pusey summarizes his paper as follows:

> 1. Salvarsan has real dangers; they are remote, but, when they occur, serious. 2. As far as can be deduced from our present knowledge there is no reason to believe that salvarsan will lessen the occurrence of parasyphilitic nervous affections, and some ground for fear that it may predispose to them, except in those cases in which it cures the disease. 3. It is a powerful symptomatic remedy. 4. In cases in which vigorous treatment is begun before the generalization of the disease there is strong ground for believing that syphilis can be aborted. This possibly applies to a few early cases with secondaries. 5. In all other cases in the secondary period its "curative" use may do more harm than good.

4. Heart in Syphilis.—Serious involvement of the heart Brooks has found to be frequent in syphilis. Epicardium, endocardium or myocardium or all together may be diseased. Cardiac involvement, he says, may develop early in the infection, though its symptoms may not be apparent until late. The signs and symptoms are those of cardiac disorder, and little or nothing except the history, general aspects and the Wassermann reaction may indicate the true etiology. Treatment should be first along indicated circulatory lines, secondary as to time, but most productive and important of all, it must be specific. Good results, cures in many instances, will follow appropriate antisyphilitic treatment. Brooks insists that the special method of treatment should be individual, but both mercury and salvarsan are efficacious in the condition; usually they are preferably combined; in some instances the former, in others the latter acts best. Iodin is an efficient adjuvant in at least some instances. Treatment should be continued until a permanent negative Wassermann is attained. Subsequent to this the management of the case should be along circulatory, not luetic lines.

5. Syphilis in Etiology of Fibrous Osteitis.—Fibrous osteitis, in some cases at least, in Skillern's opinion, is identical with late hereditary syphilis of bone. He urges that the connection of syphilis with this and other bone diseases of obscure etiology should be thoroughly worked out with the great aid now afforded by the Wassermann reaction. The disease is curable by conservative measures, and may be struck off from the fast-shrinking list of bone diseases requiring amputation.

6. Case of Strychnin Poisoning.—The case cited by Hewlett is noteworthy because of the amount of strychnin taken (15 grains). The fatal dose is commonly stated to be ½ to 1¼ grains, although according to Gadamer it is considerably higher (2 to 6 grains). Over 1 3/5 grains were recovered from the urine. The recovery of the patient was due in part to the presence of food in the stomach, which retarded the passage of the poison into the intestines and in part to the prompt emptying of the stomach at the onset of symptoms; 4½ grains were obtained from the first stomach washings, but unfortunately, the later washings were not analyzed. The case is interesting on account of the attempt to determine quantitatively the amount of strychnin excreted in the urine and the rate of excretion. During the earlier stages of the poisoning the amount of urine was diminished. At best not more than 23 c.c. per hour were excreted during this period, and it seems probable that very little urine was formed uring the acute symptoms. The marked increase in the cond portion of urine (58 c.c. per hour) Hewlett believes was due mainly to the improved renal circulation, for the salt *solution enema given forty minutes* before this urine was obtained could hardly have been solely accountable for the considerable quantity of urine. The subsequent flood of urine was evidently due *in* part to the enemata and in part to the improved renal circulation.

During the acute stages of the poisoning very little strychnin was excreted, only 1 milligram having been obtained from the urine passed five hours after taking the strychnin. Had the patient died within two hours Hewlett says still smaller amounts, probably only traces, would have been recovered from the urine. Following this period the excretion of strychnin increased rapidly, the maximum being reached in ten hours when 49 milligrams were excreted, an average of almost 1 milligram per hour. During the second day no analyses were made. On the third day a distinct trace was obtained, and on the fourth a faint trace. On the fifth day no strychnin was obtained. Altogether, about 96 milligrams (1 3/5 grains) were recovered from the urine. The analyses are noteworthy in showing (1) how little strychnin was excreted during the most acute stage of the poisoning; (2) that the major amount was excreted within twenty-four hours, and (3) that the excretion was not completed for three or four days.

7. **Insufficiency of Pulmonary Valve.**—The chief points in the diagnosis of pulmonary insufficiency are its frequent association with mitral obstruction, the diastolic murmur along the left edge of the sternum from the second interspace downward, the occurrence of marked pulmonary symptoms, with cyanosis, and the special phenomena pointed out by Gerhardt and Bamberger. Allyn believes that it is probable that relative pulmonary insufficiency occurs more frequently than we are wont to believe. Cases have been reported by Graham Steel, Gibson and more recently by Rudolph. He also regards it as not unlikely that in some of the cases of aortic insufficiency in which the diastolic murmur is heard best in the third and fourth interspace to the left of the sternum, that the explanation may be an associated pulmonary insufficiency, usually of relative character.

10. **Chronic Ulcer of Pylorus.**—The actual pathology of pyloric ulcer in La Roque's opinion is that of central necrosis of an area of inflammation, the necrosis resulting from capillary and arterial blocking by hyperplastic connective tissue and inflammatory exudate. The exciting cause of the inflammation causing the necrosis is bacterial infection. The original source of the bacteria is from some focus of inflammation in that part of the body drained by the portal vein, namely, the small intestine, appendix, cecum, colon, sigmoid, upper part of the rectum, liver, bile tract, pancreas and finally the stomach itself. The bacteria are carried to the liver through the portal vein. They are eliminated in the bile after being filtered through the liver. The infection is deposited by the bile into the proximal duodenum or according to the new nomenclature, *pyloric fundus, sac, or chamber.*

The clinical phenomena of pyloric spasm are dependent on the pathology of duodenal pyloritis. Pyloritis, pyloric ulcer, bile-tract infection, pancreatitis, and perhaps cirrhosis of the liver are late results of infection primarily located most commonly in the appendix, though in many cases in some other region drained by the portal vein; and these lesions frequently exist together in the same patient at the same time or may follow each other in rapid or slow succession. Finally, La Roque claims that the cause of pyloric ulcer (inflammation) is probably always primarily located on the duodenal side, and that so-called gastric ulcers are a result of extension of infection from the duodenal, through the lymph vessels in the wall of the pylorus to the gastric side.

11. **Tuberculous Cervical Lymphadenitis.**—After a careful history has been obtained and an examination made, Müller says, the portal of entry can usually be surmised and if necessary the tonsil, adenoid or carious tooth should be removed, or any ulcer, scab, pediculosis, otitis, etc., attended to. In those cases seen early with only a small area involved and in which the child is in good general health, an operation should be advised. If the social position permits, this dissection should be confined to the macroscopic group with a minimum scar and the child sent to the seashore and kept from school for one year; the general and hygienic details of treatment being carried out with scrupulous care. In the case of the poor child or where such cannot be carried out, Müller thinks the entire submaxillary and cervical chains above the omohyoid should be excised. The general treatment must then be carried out at home. If the case is seen late with one or both sides choked up, the Roentgen ray is often of advantage in reducing the hyperplasia and a radical dissection can be carried out at an opportune time. If caseous abscesses, sinuses, etc., exist they should be opened up, curetted out and an effort made to thoroughly clean up the tuberculous granulation tissue after which the Roentgen ray is often invaluable in promoting healing.

Müller prefers the transverse incision whenever possible, especially for the submaxillary and upper part of the deep cervical. When the mass has crossed posteriorly beneath the muscle or involved the posterior superficial cervical chain, an oblique incision from the posterior edge of the mastoid along the posterior edge of the muscle to just below its middle *and then prolonged* transversely to the thyroid muscles will give a large field area. Finally, intratracheal insufflation anesthesia offers immense advantages in difficult cases, although pharyngeal insufflation anesthesia suffices for the easy ones. At all times it is important to keep in mind that we are "not only treating a case of tuberculous glands, but are dealing with a human being infected with tuberculosis. The difference between the two points of view is enormous, and the success will largely depend on the one chosen by the physician" (Hawes).

12. **Thickening of Thiersch Grafts.**—The epithelium of Davis' patient seemed to be particularly responsive to the stimulation of amidoazotoluol, and these thickened grafts present the most remarkable condition of overgrowth which has

come under his observation. Thiersch grafts which were subsequently applied to unhealed portions of the same wound, under exactly the same conditions, but without being dressed with amidoazotoluol, were not thickened. There was also great thickening of the deep pinch grafts placed on the undisturbed granulations of an ulcer on the scalp, which had been treated with amidoazotoluol before and after the application of the grafts. There was no such thickening, however, of similar grafts placed on undisturbed granulations, when not dressed with amidoazotoluol. There was distinct overgrowth of epithelium, "pebbly formation," on the thigh, when the area from which the Thiersch grafts were removed was dressed with amidoazotoluol ointment. Another area on the thigh from which Thiersch grafts were taken, but which was dressed with boric ointment, showed no "pebbly formation." The patient has been under observation for over two years and a half since his discharge from the hospital, and there is no sign of malignant degeneration anywhere.

17. Simulating Appendicitis.—An analysis of White's cases shows that pain, tenderness and apparent tumor were present in all cases. The pain came on suddenly in two, gradually in five; it was limited to the side of the abdomen in five, and was referred to the leg in two. Four with extreme tenderness showed rigidity of the abdominal muscles on the right side, but this was probably a voluntary act. Fever was not present in any case, and the digestive disturbances seen in two of the patients were probably coincidents and had no relation to the trouble. One of the patients was markedly neurasthenic, the other six were not. Long-continued severe pain in the right iliac fossa with a marked tumor, but without fever and without digestive disturbances, White says, would indicate trouble other than appendicitis. However, it is not essential that the diagnosis should be made before operation, provided the condition is recognized, if present, as soon as the abdomen is opened. The presence of a tense tendon along the edge of the psoas magnus renders diagnosis easy through an exploratory incision.

31 Evolution of Mental Healing. C. F. Painter, Boston.

30. Anatomic and Surgical Study of Pericecal Membranes.—Fallon agrees with others that the so-called Jackson membrane is always present, and is in fact a normal structure for the following reasons: He has always found this membrane when he has looked for it; it has all the characteristics of a normal, congenital, peritoneal membrane It is a delicate structure of equal consistency throughout; even, transparent, and with orderly vascularization. It may be traced to the peritoneal plates of the omentum and may be seen to be continuous with them; especially, when an ascending mesocolon is present. But even when the ascending colon is fused to the parietal peritoneum, the veil can be seen to be continuous with the serous covering of the mesocolon by detaching the fused parietal peritoneum. Here the veil may be seen running under the parietal peritoneum, and to be continuous with the mesocolon. The same membrane envelops the remaining colon, having the same characteristics that it has on the ascending colon. This may well be seen on the transverse colon. He believes that the Jackson membrane is a congenital, normal, constant structure, and is not disabling to the cecum and ascending colon, and is not a membranous pericolitis. That there is a definite pericolitis, however, is established, but it has no relation whatever to the so-called Jackson membrane.

38. Rate of Nitrogen Elimination.—The typical curve of nitrogen elimination on a selected mixed diet Mendel and Lewis found showed a rise in the first period, reaching a maximum in the second three hours, followed by a fall to the initial level early the next day. With a definite diet it was always possible to duplicate experiments on the same animal. Different animals on the same type of diet have given parallel curves. A delay in the elimination of nitrogen was caused by the addition to the diet of such indigestible materials as mineral oil, vasoline, bone ash, paraffin, filter paper, cork, and agar-agar substances which act in a purely mechanical as contrasted with a chemical manner. Invariably there was a subnormal rate of nitrogen output in the first periods following ingestion of the meal; with paraffin, filter-paper, cork and agar-agar this was followed by a higher rate in the later periods. The effect of the indigestible materials was progressively greater in the order in which they are given above. A delayed absorption of the nitrogen intake, they believe, is presumedly responsible for the slower rate of elimination of nitrogen. As suggested: (1) a slower rate of digestion caused by an early emptying of the stomach and a consequent early exclusion of gastric proteolysis, with the possibility of a more prolonged intestinal digestion; (2) a slower rate of digestion caused by an adsorption of partially digested protein residues by the added indigestible material, making them less readily accessible to the action of the digestive enzymes; (3) an adsorption of the final digestive products by the indigestible substance whereby their absorption from the intestine is hindered.

39. Idem.—Carbohydrates in the diet, Mendel and Lewis state, cause a slower rate of elimination of nitrogen after a protein meal, the various carbohydrates studied having a progressively greater effect in the following order: starch, soluble starch, sucrose, dextrose. The experimental data do not warrant the adoption of more than a tentative theory as to the explanation of the retardation of nitrogen excretion when carbohydrates are present in the diet. It seems quite probable to the authors, however, that the protein-sparing action of carbohydrate is responsible for this delay. The effect on the nitrogen-output curve of replacing the non-nitrogenous constituents of a mixed diet by fat varied with the character of the fat as follows: (a) with the fluid cotton-seed oil there was a slower rate of nitrogen elimination; (b) with lard and "oleostearin," the nitrogen excretion in the early periods following the meal was above the normal. The apparent action of these latter fats was shown to be in reality the result of removing the sucrose from the diet. The action of cotton-seed oil *per se* was to cause a marked delay in the rate of elimination of nitrogen. Neither lard nor "oleostearin" by themselves had any effect on the nitrogen-output curve.

46. **Idem.**—Apart from the character of the protein ingested Mendel and Lewis found that a large number of diet factors—the water intake, the presence and nature of indigestible materials in the diet, the amount and character of the carbohydrate fed, and to some extent the presence of fat in the diet—play a rôle in modifying the rate of elimination of nitrogen after a meal containing protein. With most of the proteins studied the nitrogen-output curves differed to only a slight extent from one another; and in no case did the nature of the protein have a greater effect on the rate of nitrogen elimination than some of the non-protein diet factors mentioned.

47. **Composition of Milk.**—Human milk, Meigs and Marsh state, differs from cow's milk in three important ways. It contains considerably more lactose than cow's milk, and more substances of unknown nature which contain little or no nitrogen; it contains very much less protein than cow's milk. The composition of milk varies more or less regularly with the progress of lactation so that average figures for its composition are not very satisfactory. The following, however, are given as the limits of normal variation of the constituents of the two kinds of milk from the beginning of the second month of lactation onward, the figures representing percentages of whole milk:

	Fat	Lactose	Protein
Human milk	2-4	6-7.5	0.7-1.5
Cow's milk	2-4	3.5-5	2.5-4

Both kinds of milk contain substances which are important constituents of diet, which are soluble in alcohol and ether, which contain little or no nitrogen, but of which the chemical nature is still unknown. These substances are most plentiful in early human milk and diminish in amount with the progress of lactation. Early human milk contains about 1 per cent. of these unknown substances; milk from the middle period of lactation, about 0.5 per cent. Cow's milk from the middle period of lactation contains about 0.3 per cent. of the unknown substances.

Journal of Nervous and Mental Disease, Lancaster, Pa.

October, XL, No. 10, pp. 617-680

49 *Pathology of Myasthenia Gravis. S. Kuh and M. Braude, Chicago.
50 *Rôle Which Heredity Plays in Inducing Epilepsy in Children Suffering from Infantile Cerebral Palsy. L. P. Clark, New York, and E. A. Sharp, Buffalo.
51 Cerebral Palsies without Demonstrable Anatomic Findings. J. H. W. Rhein, Philadelphia.
52 Syphilitic Bone Disease of Skull. M. S. Gregory and M. J. Karpas, New York.

49. **Pathology of Myasthenia Gravis.**—Although examined serially from the lowest to the highest levels, the spinal cord of the case cited by Kuh and Braude presented but few characteristic changes, the most important consisting in occasional small areas of vascular sclerosis, recent hemorrhages, excess of glia tissue in regions in which normally it should not occur, and in the presence of corpora amylacea. An unusual finding was the presence of an aberrant bundle of fibers in the cervical region. There were present in the higher levels of the cord capillary polymorphonuclear thrombi and chromatolytic and pigmentary changes in the nerve cells. There was a rapid increase in the number of these capillary thrombi in the upper cervical, and a still greater number in the medulla oblongata in the regions of the nuclei of the lower cranial nerves, in the pyramids and sensory tract. In the proportion as the number of these thrombi increased, in just such proportion did the nerve cells in their vascular tributaries show chromatolytic and pigmentary changes. Although less pronounced, the regions of the pons and corpora quadrigemina were also the seats of a moderate number of these thrombi, which were likewise accompanied with corresponding changes in the nerve cells. There were relatively few vascular changes in the cortex and *none* in the optic thalami.

Examination of the muscles (about 50 pieces) showed only changes repeatedly described by others: great variability in the size of the muscle fibers, the presence of pale fibers, simple and degenerative atrophy, fatty degeneration, increase in the number of the sarcolemma nuclei; recent hemorrhages, interstitial perivascular infiltration of lymphocytes, plasma and mast cells. Macroscopically no trace of thymus gland. The case presented two unusual features, one clinical, not described elsewhere, namely, a feeling of fatigue produced by passive movements, and one pathologic, the occurrence of an aberrant bundle of fibers in the cervical region of the cord.

50. **Heredity in Epilepsy in Children.**—Clark and Sharp are of the opinion that the heredity factor in hemiplegic epilepsy is only a little less in evidence than that of genuine epilepsy, and that the prognosis as to a sequential epilepsy following in the wake of a given case of infantile cerebral palsy should be based on the presence and degree of spasmophilic or simple neurotic history, and that this latter fact should be given as much or even more weight than the site, nature and degree of the initial cerebral injury as expressed in the palsy.

59 *Reversible Action of Adrenalin and Some Kindred Drugs on Bronchioles. F. L. Golla and W. L. Symes, London.

57. **Treatment of Experimental Beriberi.**—Voegtlin and Towles found that an aqueous extract of autolysed spinal cord from which coagulable protein has been removed, contains an antineuritic substance which cures symptoms of polyneuritis in rice-fed birds in daily doses corresponding to 4 grams of dried cord. This substance, when added to a diet of polished rice, is capable of removing the nervous symptoms of the disease, but cannot reestablish a normal metabolism, nor enable the affected birds to recover their body weight. The antineuritic substance is liberated through autolysis from the nerve fiber.

58. **Action of Digitalis on Coronary Artery.**—The pharmacologic action of various drugs on the coronary artery was studied by Voegtlin and Macht directly, that is, by the use of excised arterial rings or strips. Rings of the coronary arteries of the ox and the pig were used. Digitoxin, digitalin, digitonin, digitalein, digalen, bufagin, cymarin, strophanthin, tincture of digitalis, infusum digitalis, amyl nitrite, sodium nitrite, nitroglycerin, erythrol tetranitrite and theobromin were the substances used. It was found that digitonin and digalen produce relaxation, while digitoxin, digitalin and bufagin cause a constriction of the coronary arteries. It seemed that digitonin is responsible for the relaxation produced by digalen and the infusion of digitalis, for it is known that the infusion of digitalis and digalen both contain that body. All the nitrites were also found to produce relaxation. It was furthermore noted that the two sets of drugs, the nitrites and digitalis-like bodies, can antagonize each other in their action.

Work done on the physiology and pharmacology of circulation would seem to indicate that the action of the above drugs would be the same on the intact mammalian heart. The vasoconstrictors of the coronaries run in the vagus nerve, and knowing the powerful vagus action of digitoxin and bufagin, the coronary constriction if anything might be even accentuated in life. Whenever, therefore, coronary spasm is to be avoided or guarded against, it would be advisable to employ the digitonin-containing preparations, or simultaneously administer the nitrites. Furthermore, if angina pectoris is due, as is generally assumed, to spasm of the coronary vessels, the authors are of the opinion that their results would certainly tend to explain the favorable action of the nitrites in coronary angina.

59. Reversible Action of Epinephrin.—Golla and Symes found that the action of epinephrin, epinine, tyramine, and some other amines and alkaloids, on normal bronchioles, is constriction. *This constriction is not parallel to*, and usually outlasts the accompanying vascular change. It is abolished by urethane. It is not attributable to secretion. It is, therefore, contraction of bronchiolar muscle. After bronchiolar constriction by certain other drugs, adrenalin, etc., produce bronchiolar dilatation. Among drugs after which the normal action of adrenalin, etc., is reversed, are curare, ergotoxin, apocodein, pilocarpin, muscarin and physostigmin. The tracheal muscle differs in its reactions from that of the bronchioles.

104 Treatment of Fractures near Wrist Joint with Special Reference to Colles' Fracture. A. O. Wilensky, New York.

100. Theobromin Sodium Salicylate.—The object of Neuhof's communication is to show the practicability of intravenous theobromin sodium salicylate injections. The solution is readily prepared and sterilized, and when properly given produces no reaction. While 20 c.c. of a 5 per cent. solution have been found a convenient standard, it may be modified to suit individual requirements. It seems particularly indicated in uremia, in the anuria of cardiovascular renal diseases, and in some types of primary renal disease when internal administration is impracticable or impossible and quick diuretic action is necessary. It is further suggested that these injections may be of benefit in some types of uremia accompanying eclampsia; in conjunction with other forms of treatment, it may help in starting diuresis.

128 Incinerator. A. Farenholt, U. S. Navy.

125. Recurrent Dislocation of Shoulder.—The technic employed by Williams is described as *follows:* Incision 4½ inches in length from tip of the coracoid along the inner border of the cephalic vein, exposing the vein. The fibers of the deltoid were separated by blunt dissection and the insertion of the pectoralis major exposed. The upper two-thirds of the fibers of this muscle were divided on a director and the arm was rotated outward, exposing the flat tendon of the subscapularis tightly stretched over the head of the bone. The upper half or more of the tendon of insertion of this muscle was similarly divided, thus bringing into view the anterior and inferior portions of the capsule. The capsule was incised in a vertical direction for a distance of 1½ inches. The tips of two fingers could be easily inserted between the lower portions of the capsule and the articular surfaces. The margins of the incision were overlapped for a distance of three-quarters of an inch by four mattress sutures of chromic catgut in the same manner that the aponeurosis is overlapped in operating on ventral hernia. The free margin of the incised capsule was slipped down to the outer surface of the capsule by a continuous chromic suture. The divided tendons of the subscapularis and pectoralis major were next carefully united with interrupted chromic gut stitches. Several chromic gut stitches were used to bring together the separated fibers of the deltoid: the skin wound was closed with interrupted sutures. Recovery was uneventful, healing occurring by primary union. Passive motion was begun on the fifth day. The patient was discharged to duty nine weeks after the operation.

127. **Iodized Gauze for First-Aid Packet.**—The gauze used in the first-aid packet of the U. S. navy has been treated with the following: iodin, 10 parts; potassium iodid, 15 parts; water (a sufficient quantity to dissolve). The gauze is colored a deep brown and thoroughly impregnated with iodin. It answers the double purpose of being a confusion color, which is not to be detected from the surrounding terrain, and of supplying an iodin dressing to the surface applied, and in that iodin is conceded to be the most efficient topical antiseptic. The gauze, thus iodized, not only insures the military purpose of invisibility but furnishes an ideal method for preventing sepsis.

14. **Idioventricular Rhythm.**—The conclusions arrived at by Robinson from a study of polygraphic tracings are that the infrequency of the pulse-rate is due primarily to a relative delay in the rate of stimulus formation at the sinus. This, together with an extrasystolic contraction of the auricle not followed by a ventricular response, causes the period before effective stimulation of the ventricle coming from the normal situation to be so long that the ventricle escapes, and in turn produces auricular contraction by a retrograde stimulation, thus producing the establishment of the idioventricular rhythm.

17. **Genesis of Cancer.**—The internal transformation changes of tissue were made the subject of study by Turnbull. His results are based on 25,000 measurements and over 300 calculations. They establish what he believes to be a principle of the first magnitude in the cancer problem, namely: There exists a relation between the strain to which a tissue is exposed and the extent to which that tissue varies. This principle he thinks offers a rational explanation of the transformation of normal into cancerous tissue without it being necessary to think of any external cause for cancer whatsoever, for example, parasites. The above results indicate that cancer is explainable as an internal, compensatory and essentially physiologic tissue-change. If the above results be true then cancer is not infectious.

41. **Fever in Pulmonary Tuberculosis.**—Wethered emphasizes the fact that a rise of temperature in pulmonary tuberculosis, apart from accidental factors, may be considered an indication of activity, and that the most reliable means for reducing activity is rest. If, therefore, a patient who has been progressing favorably exhibits a rise of temperature, it must be accepted as a sign that rest must be insisted on. In other words, a patient suffering from pulmonary tuberculosis must live in accordance with his temperature chart. Any increase of cough and expectoration, headache, general

malaise, and so on, should always be regarded as calling for a record of the temperature for a few days, and should a rise be found the necessary measures should be taken in accordance with the general features of the case.

47. Arteriovenous Anastomosis for Impending Gangrene.—This operation was performed by Goodman in fifteen cases on the femoral vessels, and in this series he noted that the foot, previously cold and cadaverous in appearance, took on a feeling of warmth and a healthy pink color. The valves of the veins were only a temporary barrier to the course of the blood against the constant pounding of the heart. The pain due to ischemia was relieved shortly after the operation in all these cases. Strongly presumptive evidence of establishing a reversal of the circulation are the following facts: improvement of color, increase of warmth of the affected part, relief from pain, filling of the superficial veins, pulsation of veins below site of anastomosis, and return of part threatened with gangrene, or the actual seat of gangrene, to the normal. Goodman had six successes. Several of these cases which promised success required amputation later, but even these had temporary relief from pain. He used the end-to-end method in all excepting one case, as he found it the simplest in execution and least likely to cause thrombosis. The operation should not be undertaken in the presence of sepsis, advanced or fulminating gangrene. The opportune time for intervention is in the pregangrenous stage before mortification has set in, in order to prevent its inception. In nonseptic gangrene the improved nutrition of the limb may be hoped for, permitting lower amputation than would otherwise be possible. The utmost delicacy and skill in minute detail must be observed in order to avoid the formation of thrombi; a most rigid asepsis is required throughout the operation, or the object of the operation will be defeated. Goodman made thirteen end-to-end anastomoses, one side-to-side, and in two of the cases an exposure of the vessel showed that an attempt to anastomose was not warranted on account of the advanced stage of thrombosis of the vessels. In two cases with gangrene a low amputation seemed to be satisfactory. Of the eight cases which were failures, including one death, one was a side-to-side anastomosis, and three of the remainder should not have been operated on on account of the presence of spreading gangrene.

55 *Type of Cerebral Maldevelopment (Forebrain Aplasia). G. A. Sutherland and H. Paterson.
56 *Sulphemoglobinemia. R. L. M. Wallis.

51. Auricular Flutter.—In one case examined by Ritchie, auricular flutter, at a rate usually of 250 to 276 per minute, persisted almost uninterruptedly for seven and a half years. The auricles meanwhile were not under vagus control. The flutter had then been replaced by an auricular tachysystole at a rate of 187 to 201 per minute, the form of the auricular deflexions had changed and the auricles were under vagus control. The pathologic changes are described in a heart that presented auricular flutter ten days before death. There were slight, diffuse inflammatory processes in the myocardium. Both nodes, the bundle and its branches, were slightly affected. The clinical and electrocardiographic features are described in a new case presenting transitions between auricular flutter, fibrillation and an intermediate form of auricular activity.

52. Variations in Excretion of Endogenous Uric Acid.—Graham and Poulton found that the consumption of a diet consisting of protein and fat of insufficient caloric value causes a fall in the endogenous uric acid output of between 30 and 50 per cent. If most of the fat in the previous diet is replaced by carbohydrate, there is no fall in the output of endogenous uric acid. A fall in the endogenous uric acid is also produced in two other conditions: (a) starvation during the first few days; (b) the consumption of a carbohydrate and fat diet. The following possible causes to account for the diminution in the uric acid output have been considered by the authors: (a) diminution in protein metabolism; (b) loss of body protein; (c) acidosis; (d) increased fat metabolism; (e) the interaction of protein and carbohydrate metabolism. Decided objections are raised to the first four hypotheses, but the last hypothesis seems to agree with the facts observed by other authors and Graham and Poulton.

54. Strychnin in Heart Failure.—An inquiry was undertaken by Parkinson and Rowlands to obtain evidence as to its immediate effect when given subcutaneously in cases of severe heart failure. The blood-pressure, rate and regularity of pulse, rate of respiration and general condition were recorded for an hour after each injection. The action of repeated doses was not investigated. Fifty patients were examined on admission and approved if they presented symptoms and signs of severe heart failure with or without valvular disease; those with heart failure secondary to pulmonary or renal disease were excluded, as were those with pyrexia. Most of the patients showed orthopnea and edema of the legs; all had shortness of breath. Strychnin sulphate in a dose of one-fifteenth of a grain (1/15 gr. = 0.0044 gm.) was given subcutaneously in each experiment. Before any observations were made the patient was allowed to remain quietly at rest in bed for three to eight hours, and during this period no drugs were administered. After the injection, records were made at the end of each period of five minutes during one hour. In cases with regular rhythm on no occasion was any increase in blood-pressure produced. The average rate of the pulse before injection was 107.6, and after injection 104.0, a slight decrease of 3.3 beats per minute. The authors ascribe this fall to the same factors as mentioned above under blood-pressure.

The rate of respiration was unaffected by strychnin. No change in amplitude of respiratory movement was noted. In four cases out of the twenty-five Cheyne-Stokes breathing was recorded on the respiratory tracing. Strychnin had no effect on this abnormal respiratory rhythm. In twenty-five cases with auricular fibrillation the average rate of the pulse decreased by only 3.4 beats per minute in the hour following the injection. None presented any change in irregularity. The average rate of respiration showed a decrease of not more than one or two respirations per minute alike after strychnin and after pure water. No change was observed in the amplitude of respiratory movements. In one case Cheyne-Stokes respiration was recorded; this remained unaffected by the injection. The authors conclude that strychnin has no effect which justifies its employment as a rapid cardiac stimulant in cases of heart failure.

55. Type of Cerebral Maldevelopment.—Sutherland and Paterson draw attention to a peculiar form of cerebral maldevelopment which produces a characteristic series of symptoms during life and which presents after death definite pathologic changes. Their experience is limited to two cases. Both patients were females. Both appeared to be healthy at birth and at the end of the second week developed "convulsions" or twitching movements. No evidence of syphilis or tuberculosis was discovered either during life or after death. No external evidences of maldevelopment were seen. The heads were rather small, but there was nothing suggestive of a condition of microcephaly. The fontanelle did not pulsate and was not bulging.

What was very striking was the curiously apathetic condition in which the child lay, never smiling or looking about, or taking notice of anything. The same placid look of calm indifference was always maintained. No gleam of intelligence was ever present, and no evidence that the child could see or hear.

An examination of the eyes showed nystagmus in both cases, but no changes in the fundi. Fits of crying occurred at irregular intervals and would sometimes last for hours. The cry was more like the yapping of a dog, regular, monotonous, weird, expressionless and invariably of the same nature in the individual patient. The character of the crying suggested an automatic discharge of energy at regular intervals. At times there was an abortive cry, that is, the face was screwed up into the expression of crying but no sound was elicited. At rarer intervals screaming of a loud and piercing character was present, but without any sign of pain or distress, and without any obvious cause. Yawning was a marked feature throughout and of frequent occurrence. Slowly opening its mouth the infant threw its head back, then stretched its limbs, then flexed them—in short, the whole process of a leisurely yawn was gone through. Sucking and swallowing were seriously interfered with, and this difficulty appeared to increase from week to week. The respiration was markedly altered. Tachypnea lasting for hours or days was present in both cases. The breathing was always of the so-called medullary type, that is, superficial, almost purely abdominal, and without any sign of distress. There was no evidence of any pulmonary disease. The breathing was often cyclic, spells of active breathing lasting for from nine to thirty-seven seconds, being followed by periods of apnea, lasting for from four to twelve seconds. The longer the spell of breathing, the longer was the apneic period. A long period of respiration usually showed a uniform curve, while the shorter spells were marked by great variation in the depth and rate of breathing.

Attacks of tachycardia were frequently noted in both patients, the cardiac rate rising to 200 beats per minute. The sounds of the heart at those times were of fetal character, but no evidence of cardiac disease was detected and no signs of cardiac weakness were present. Clinically, the cardiac condition was very similar to that seen in paroxysmal tachycardia. The attacks of tachycardia and tachypnea were sometimes associated and sometimes not. Pyrexial disturbance was a marked feature in one case, less marked in the other. The temperature would run up suddenly to 104 or 105 F., the skin would become quite red, and profuse sweating usually occurred. No cause for these attacks could be found on physicial examination. Sensation seemed to be entirely absent. Twitching of the limbs, which was the first symptom noted in both cases, was a marked feature throughout. Clonic spasms and tonic spasms were present, sometimes continuous for days and sometimes absent for days, but always tending to become more pronounced and more persistent in the form of rigidity. Twitching was less marked in the face than in the limbs. The upper extremities tended to become flexed at the elbows, while the lower limbs were extended at the knees. The feet and hands were often fixed in the position of tetany. Tapping the skull with the finger would sometimes induce immediately a clonic and then a tonic spasm of the trunk and extremities. Opisthotonos was an early and progressive symptom, although at times it passed off altogether, and at other times was very pronounced. Even more striking, because of its rarity in infancy, was a condition of pleurosthotonos which was present in both cases. At the necropsy the brain was found extremely ill developed (or atrophied) as regards the cerebral lobes, with the exception of the extreme hinder portions of the posterior lobes, which appeared to be normal.. The cerebellum, the medulla, the pons and the basal ganglia presented a normal appearance. The lateral ventricles were not dilated, the foramen of Monro was patent and normal, the third and fourth ventricles were not enlarged, and the patency of the *iter* was established.

56. **Sulphemoglobinemia.**—Five cases of sulphemoglobinemia examined by Wallis all showed the characteristic features of this disease, viz., marked cyanosis, weakness, headache, and constipation without signs of any lesion in the heart and lungs. The sulphemoglobin partially replaces the oxyhemoglobin of the blood and is present in the red blood-corpuscles and not in the serum. The serum of all the patients contained a strong reducing substance, possibly of the nature of a hydroxylamin derivative capable of producing reduction of the oxyhemoglobin. This, Wallis says, is an essential and primary stage in the production of sulphemoglobin. A nitroso-bacillus occurred in the buccal cavity of these patients, and from its biochemical characters appeared to be capable of producing such a reducing substance. The sulphuretted hydrogen present in the body was in sufficient quantity to form sulphemoglobin under these conditions.

Annales de Gynécologie et d'Obstétrique, Paris

September, XL, No. 9, pp. 497-560

57 *Uterine Cancer. (Valeur comparée des procédés opératoires du cancer de l'utérus et des résultats obtenus.) D. De Ott. (Le cancer de l'utérus "col et corps.") E. Wertheim.

57. **Cancer of the Uterus.**—These two articles were presented by request at the recent international medical congress. Ott is known as the apostle of extensive vaginal and Wertheim of extensive abdominal hysterectomy for cancer. The former states that while his percentage of permanent recoveries is a little smaller than with the abdominal technic, yet the number of persons actually cured is higher than with the abdominal technic as none was damaged in any way by the vaginal operation, while the operative injuries and by-effects from the abdominal operation lead comparatively frequently to fatal complications. Ott grants that once past the breakers, a larger proportion of the individuals left are cured, but he claims that by avoiding the breakers a bigger crowd of patients start on the road to recovery, and the percentages are thus not comparable between the two groups. His total mortality in 345 vaginal hysterectomies for uterine cancer was 1.7. Of the 246 patients whose fate is known after five years, 34.1 per cent. seem to be permanently cured. There is thus a proportion of seventeen permanent cures to one fatality (17 to 1). He tabulates along with his figures Wertheim's published statistics in 500 abdominal cases; the immediate mortality was 19.4 per cent.; of the 180 patients whose fate is known after five years, 57.6 per cent. seem to be permanently cured. The proportion of permanent cures to one fatality is, however, only as 1.7 to 1.

Wertheim's article brings his statistics down to date; abdominal operations for cancer of the cervix in 714 cases; primary mortality 18.6 per cent.; the permanently cured after five years, 186 or 42.5 per cent. Among this group cured for five years are 14 patients whose lymph-nodes showed malignant involvement at the time of the operation. He had postoperative necrosis of the ureter in 6 per cent. of the total 714 cases. He found only 50 per cent. operable of the 1,501 cases encountered during the fifteen years since he introduced his more extensive technic.

Ott sums up his comparison of the end-results with the two methods in the statement: "With the abdominal technic, one gets one and a half times more chance of permanent recovery after five years, but one runs eleven times more danger of dying during or immediately after the operation." (Ott's vaginal operation is done with special endoscopes, some of which were illustrated in THE JOURNAL, 1902, xxxix, 458. He does not describe his technic in this article.)

October 1, XVII, No. 19, pp. 633-668

58 *Familial Purpura; Three Cases. M. Cousin.
59 *Case of Meningitis with Serotherapy. (Méningite cérébro-spinale à méningocoques. Accidents sériques.—Guérison.) Giraud and Marnay.
60 *Early Operative Treatment of Congenital Spastic Paralysis. P. Redard.

58. **Familial Purpura.**—Cousin states that a child of 10 developed purpura; three years later his cousin, of about the same age, and four years later a more distant cousin. The family has a history of bleeding easily but no actual hemophilia is known. Cousin gave calcium chlorid to each of the children and the effect was promptly apparent. He ordered 1 gm. a day in a very dilute solution, and the extremely severe purpura in each case abated under its influence and there has been no return since. Two of the children are now sturdy youths, but the third is inclined to be delicate. The calcium chlorid acts on the cause of the purpura, and consequently it should be supplemented by symptomatic measures until its effect is apparent.

59. **Serotherapy in Meningitis.**—The meningitis in the case reported developed in three stages, first ten days of true mea-

ingitis subsiding under serotherapy and followed by an interval of six days almost free from symptoms. Then the temperature ran up again, the symptoms of meningitis returned and the parotid gland swelled. Then 20 c.c. of the antimeningitis serum was injected, nine days after the first injection. No therapeutic effect followed but the next day diffuse urticaria developed, with pains in the joints and severe contractures resembling spastic paralysis. They persisted severe for several days and then gradually subsided so the child entered on his convalescence in seven days, a month after the first symptoms. This case is compared with other literature on the serotherapy of meningitis, and the disturbances that followed the serum are ascribed to direct irritation of the meninges by the serum; it is not necessary to invoke anaphylaxis. Disturbances of this kind have been noted even after a first injection; Sicard and Salin have reported cases in which the temperature ran up and headache, nausea and the Kernig sign followed on injection of saline or antimeningitis serum and necropsy revealed intense congestion of the pia with infiltration. The serum evidently induces an inflammatory reaction, but this generally escapes notice as it is masked by the more prominent symptoms of the original meningitis. The above syndrome cannot be ascribed to anaphylaxis, but it may be associated with manifestations of true anaphylaxis.

60. **Congenital Spastic Paralysis.**—Redard believes in operating early for Little's disease, between the ages of 3 and 5. He begins with a course of massage, baths and sedatives to prepare the little patient, and then strives (1) to do away with all peripheral sources of irritation; (2) to reduce the exaggerated reflex action, the muscular spasm, aiming to train the contracted muscles and their antagonists, and (3) to prevent and correct vicious attitudes and deformity. Redard's article was read at the recent International Medical Congress; it discusses the various operations required to meet the individual conditions and extols the advantage of means—such as vertical extension—to stretch the spinal cord and thus reduce its irritability. This alone may lead to notable reduction in the spasms, diminish the reflex excitability and permit better use of the muscles. He sometimes trains the child to walk while it is still held up in vertical extension. The Foerster operation is so severe it should be restricted to exceptional cases, but transplanting of muscles and tendons often proves surprisingly effectual. In the moderately serious cases improvement under operative and orthopedic measures is always notable and frequently it amounts to an absolute cure.

62 Comparison of Hydrocele Fluid with the Blood Plasma. L. Delrez.
63 Gastro-Enterostomy with Retracted Mesocolon. (Gastro-entérostomie postérieure anté-colique.) P. Mauclaire.

61. **Dislocation of the Joint Between the Trapezium and the Metacarpal Bone of Thumb.**—Regnault gives the history of this dislocation as presented in the literature and describes a plaster mitten devised to correct it. In twenty-two cases he has compiled, including two from his own experience, the dislocation was backward and incomplete and there was no fracture; in fourteen cases there was complete dislocation without fracture; eight cases in which the luxation was complicated with a Bennett fracture and other cases bring the total to fifty-three. Few of the patients have been seen since, so that the question as to facile recurrence of the dislocation is still undecided. To ward off recurrence it is wise to keep up treatment a long time and warn the patient of the possibility of recurrence.

68 Megacolon. (Maladie de Hirschsprung.) A. Mamrot.

67. **Kala-Azar in Italy.**—Jemma states that the disease was described in Italy as early as 1880, under the name of infectious *infantile pseudoleukemia or infectious splenic* anemia. It is the work of Leishman's parasite, and it attacks mostly young children. The younger the child the more rapid the course; recovery is very rare. Only three of ninety of his patients recovered, but in six the outcome has not been determined. He adds that the recovery was spontaneous in the three cases with a favorable outcome and can scarcely be credited to the iron, arsenic and roentgenotherapy applied. Vaccine therapy proved useless, and nothing can be hoped from splenectomy as the parasites are not localized exclusively in the spleen.

69 *Jaundice Following Abortion. Andérodias and Drouin.

69. **Jaundice Following Abortion.**—The first patient had puerperal septicemia favored by a recent influenzal attack. The jaundice was accompanied by slight rigidity of the back of the neck and Kernig sign, exaggerated reflexes, epistaxis, mild diarrhea and phlebitis of the left leg, but recovery gradually followed. The other patient was a II-para of 24, who induced the abortion herself with an ivory catheter through which she injected a little hydrant water into the uterus. The next day she had chills, vomited, and noticed that her skin had "turned all yellow." There were also severe abdominal pains and diarrhea. The uterus was curetted and an abscess of fixation was applied. Intense pruritus, hemorrhages from nose and vagina, hemoglobinuria, delirium and other symptoms of uremia grew gradually worse, the patient dying the seventh day, persistently refusing to permit an operation on the kidney. Necropsy showed necrotic nephritis and also patches of inflammation in the liver. In the first case the low urobilin content in the urine had indicated that the prognosis was not so grave as the various symptoms had seemed to suggest, and this assumption was confirmed by the prompt recovery.

74 *Diagnosis of Effusion in the Pericardium, and Puncture through the Epigastrium. A. B. Marfan.

October 8, No. 41, pp. 481-492

75 Venom Activation and its Diagnostic Significance. (Réaction d'activation du venin du cobra; sa fréquence au cours des maladies mentales; sa valeur prognostique chez les paralytiques généraux et les déments précoces.) M. Klippel and M. P. Weil.

74. **Diagnosis of Effusion in the Pericardium.**—Marfan remarks that none of the signs of effusion in the pericardium are absolutely reliable. The most instructive are the enlargement of the area of dulness over the heart and its change from a triangular to an ovoid or dome shape and the absence of pulsation seen at the edges; pulsus paradoxus; difficulty in swallowing; the pseudopleuritic findings at the left base, pronounced as the patient stands, diminishing in the knee-chest position, and the crowding down of the liver. A positive differential diagnosis is possible only by puncture. With the usual technics, puncture is inconvenient and dangerous, but it is very simple and easy and leaves the pleura and peritoneum

intact if the needle (a 6 or 8 cm. long lumbar-puncture needle) is introduced just below and close to the xiphoid appendix on the median line. The tip is slanted upward and kept as close to the rear of the xiphoid appendix and the sternum as possible, the handle pressed down on the abdomen more and more as the needle is pushed in, the needle thus pushed along the bone as if to shave it. The tip enters the pericardium at a depth of about 4 cm. in children under 5, and 6 cm. in adults. The needle traverses the cellular fat tissue between the points of attachment of the diaphragm to the sternum, not touching the muscle, and enters the pericardium at the lowest point, where all the fluid can be most readily siphoned out. This epigastric puncture of the pericardium has been done since 1911 twenty-six times on eight patients, and always with the best results. In case of tuberculous pericarditis with effusion, pericardotomy may occasionally be preferable, and it is always better when the effusion is purulent unless the process is tuberculous; in this case repeated puncture may be better as pleurotomy in purulent tuberculous pleurisy generally proves disastrous. With all other effusions in the pericardium, the epigastric puncture, repeated as needed, is the logical and harmless treatment. He reports a case of purulent tuberculous pleurisy in which complete recovery followed nineteen simple punctures.

76. Brain and Spinal Cord Tumors.—Of the 168 patients operated on under the diagnosis of "brain tumor" at von Eiselsberg's clinic, the lesion was in the cerebrum in seventy-five; in the hypophysis in sixteen; in the cerebellum in thirty-two and in the pontine angle in seventeen, while in twenty-eight cases the intervention was restricted to making a safety valve without ascertaining the exact site of the tumor. Forty operations were done on the spine, for tumors in seventeen cases, fracture of vertebrae in six, for spondylitis in two, and for spastic paralysis in fifteen. The details of all the cases are given, with nineteen diagrams; the article fills 159 pages. The site of the tumor had been correctly located in forty-six of fifty-seven cases of brain tumor. In one case a tumor was located but operation revealed multiple gliomas; the absence of the abdominal wall reflexes in this case might have warned that the trouble was of a more diffuse nature. In another case the local tenderness to tapping led to assumption of a compressing process in the angular gyrus, but the tumor was found at the junction of the hemispheres. In another, local tenderness indicated a single lesion but a bilateral affection was indicated by the tendency to fall over backward and to the left and by incontinence in respect to both urine and feces. A process in the central convolution was the diagnosis in one case; as it was exposed the fluid spurted. The trouble was attributed to circumscribed serous meningitis and no further search was made. Necropsy revealed a fibroma in the region of the acoustic nerve which could easily have been shelled out; the coincidence of the two processes was probably merely casual. A glioma in the optic thalamus had caused absolutely no symptoms of the quadrigeminal area, only symptoms suggesting compression in the inferior cranial fossa, ataxia, absence of the corneal reflex, diminished palate reflex, hemiparesis and vomiting of coffee-ground masses. Among the mistakes of the surgeon were the overlooking of a tumor and failure to recognize a diffuse glioma. This latter mistake teaches the necessity for making frozen sections during the operation when the findings are dubious. Choked disk did not accompany the tumor in the brain in every instance. If the cochlear and the vestibular nerves are dead to stimuli, this is generally pathognomonic of a tumor in the cerebellopontine angle as a rule, but this sign failed in one of the cases reported. If more attention had been paid to the ear findings in the diagnosis of abnormally high intracranial pressure and in local diagnosis, some of the mistakes might have been avoided, especially with tumors supposed to be in the posterior cranial fossa.

The patients are prepared with hexamethylenamin and, if the blood shows low coagulating power, calcium lactate is given for a few days. The tendency is more and more to operate at two sittings and to turn back larger flaps, sacrificing at need patches of the dura as large as a man's palm, closing the gap with fascia lata from the thigh. No draining or tamponing. Sixteen of the patients succumbed to postoperative meningitis; it might possibly have been avoided in some of the cases if fascia substitution had been applied. It appears from the tables that twenty-seven of the patients were cured and twenty-five improved in the intracranial operations, and three cured and sixteen improved in the operations on the spinal cord.

78. Omentum Flaps for Arresting Hemorrhage from the Liver.—Jacquin states that a pedunculated flap of omentum is easily obtained and it proved absolutely effectual in dogs after resection of large portions of the liver.

82. Malpractice in Connection with Abortion.—The Niebergall case has attracted considerable attention abroad, and Hegar discusses the lessons to be learned therefrom. The case concluded with the conviction of Dr. Niebergall for having contributed to bring on abortion by using a catheter in examining the uterus of a young girl, only 15, who complained of abdominal pains and stated that menstruation had always been irregular and scanty. He made an examination, using a catheter; it entered for more than 7 cm. and he withdrew it and asked if pregnancy were possible. Five days later, in lifting a heavy bed, the girl was seized with pains and after four days aborted. Prof. von Herff accused Niebergall of criminal abortion as the head of the fetus showed an abrasion. Hegar expatiates on the serious consequences liable with abortion under all circumstances. Even with therapeutic laminaria abortion, Aschoff found pronounced catarrhal changes in the tubes in 55 per cent. of thirty-eight cases. In one instance pus was found in the abdominal cavity. The traces of such changes as these may have serious pathologic results earlier or later even when the abortion was induced in a hospital with scrupulous care. Hegar comments on the peculiar injury it is to a physician to come into conflict with the authorities at any time and for any cause. Even when proved absolutely guiltless, some smirch still clings to him, so he urges all to suspect always a possible pregnancy, even when it is wildly improbable, and never use the sound or catheter in examining a woman in the child-bearing age. The point on which he specially insists is that in the cases which might lead to criminal abortion, it really is immaterial to learn at once whether the woman is pregnant or not. Under all such circumstances waiting a little will do no harm. On the other hand, with malignant tumors and constitutional disease, the child's chance for viability is so small that the fetus need not be taken into account. At two months a pregnancy can be diagnosed with certainty by examination without instruments, although general anesthesia may sometimes be required for it. He scarcely ever found occasion to use a catheter in exploratory examination in the later decades of his practice, and his pupils avoid its use likewise.

85. **Meningocele Interfering with Delivery.**—Kröner reviews eighteen cases; in ten there had been deflexion presentation and this group he summarizes in detail. The data show that occipital meningoceles frequently entail frontal or face presentation; sometimes a transverse face rotates around the symphysis. With a meningocele at the back of the neck, presentation occurs generally as a deflexion presentation; delivery can occur only by a change to occipital presentation.

86. **Urine Fistulas.**—Minakuchi tabulates the details of forty-five cases from the Tübingen gynecologic clinic, including eleven in which the ureter was involved; the others were in the bladder. In fifteen cases the fistula was the result of obstetric injury; in twelve, of operative injury. The results of operative measures applied are also tabulated; 91.3 per cent. were cured and all were much improved of the bladder cases, but only three were cured in six ureter cases and one improved.

87. **Therapeutic Pneumothorax.**—Zink writes from the Basel sanatorium at Davos to describe his experiences with artificial pneumothorax applied in 110 cases. He devotes thirty-seven pages to tabulation of the details, with diagrams of a number of the cases. He was able to accomplish the purpose of an effectual pneumothorax in eighty-one patients; the lung was completely compressed in thirty-five, while in forty-six, adhesions interfered to some extent. The adhesions generally stretched in time so that the therapeutic effect was finally attained. His experience teaches that nontuberculous affections of the lung and bronchiectasia are not suited for this treatment. Emphysema and asthma are also contra-indications, as also non-tuberculous disease of the kidney or heart or other organs. With tuberculous intestinal disease, it is better not to attempt the pneumothorax treatment but laryngeal tuberculosis does not contra-indicate it, but may even heal under its influence. The field of pneumothorax treatment is in all chronic destructive, tuberculous processes with a tendency to fibrous degeneration and cavity formation, restricted to one lobe; also in all severe acute infiltrating and cheesy-pneumonic forms; also in the chronic infiltrating forms without much destruction if they are of a progressive character or show no tendency to retrogression under prolonged treatment by other means. With an isolated tuberculous process in the lower lobe, there is generally bronchiectasia which renders the outlook graver; the decision must be made from case to case. With severe and recurring hemoptysis, the pneumothorax may be justified even with tuberculous involvement of the other side, but otherwise active tuberculosis of the other side contra-indicates this method of treatment. Small stationary processes in the upper lobe of the other lung do not contra-indicate the method but when the lower lobe is diseased it is better to refrain.

88. **Graduated Tuberculin Test.**—Kögel extols the method of the graduated tuberculin test, according to Ellermann and Erlandsen's technic (described in THE JOURNAL, 1909, lii, 1.634). The findings are particularly instructive for prognosis. An active response is generally a good sign, especially when the outlook is dubious. Repeated application of the graduated test also proves an instructive guide to treatment.

89. **The Organ Reaction to the Subcutaneous Tuberculin Test.**—Sons applies the term "organ reaction" rather than "focal" or "local" as this term includes a system of organs, such as the joints, for instance. He emphasizes that the organ reaction is the most instructive, the most impressive and the most reliable sign of the localization of tuberculous disease. He has made a special study of the organ reaction in a number of nontuberculous abnormal conditions, especially asthenia universalis and rheumatic arthritis, as well as in the tuberculous. In seventeen cases of the asthenic syndrome, including anemia, chlorosis and neurasthenia, a pronounced febrile general reaction to the classic tuberculin test was obtained in twelve cases. In one case of acute articular rheumatism a strong reaction was obtained, general and at the point of injection, and also in nearly all the joints. In twelve cases of chronic rheumatic polyarthritis there was a general and febrile reaction in seven cases but weaker than in the preceding group; in the five other cases there was no general reaction but an unmistakable reaction in the joints. The test applied in five cases of neuralgia and one of spinal paralysis gave only one organ reaction, and positive reactions of all kinds in the paralytic. In nine tuberculous patients the reaction was negative in the old healed cases and there was no organ reaction in one case of apical tuberculosis without bacilli in the sputum. In six cases of other affections, not tuberculous, no organ reaction was obtained but a general reaction was evident in the three diabetics. These findings point to a possible tuberculous origin in many cases of asthenia universalis and of rheumatism, both acute and chronic.

92. **Diagnosis of Injury of the Heart.**—Häcker says that if a firearm or stab-wound of the heart is not fatal at once, it permits calm examination of the patient and his being carried to the hospital if not too far away. He reports two cases instructive from the standpoint of diagnosis. In one a bullet in the skull complicated matters, and there was no sign of accumulation of blood in the pericardium pressing on the heart, and the outline of the heart was normal on roentgenoscopy. Several hours had elapsed before the man was first seen and yet the pulse was fairly regular and there was none of the cyanosis of the face usual with injury of the heart. Roentgenoscopy, however, showed that the bullet must have passed through the heart and necropsy confirmed this to have been the case but not a drop of blood had escaped. The bullet holes must have closed up at once by a valve-action. The bullet in the brain may have cooperated in slackening the action of the heart. In the second case the bullet was seen by roentgenoscopy inside the shadow of the heart and it moved with the heart beat, but it caused no symptoms and the patient was discharged in less than a month free from all disturbances. The bullet evidently must be in the pericardium and it did not enter the heart proper.

93. **Fascia Grafts.**—Kirschner has been one of the pioneers in autoplastic fascia operations, and he here gives a detailed and profusely illustrated account of his experiences. He emphasizes the superiority of the autograft technic and the superior advantages of fascia tissue for the purpose. The number of different ways in which strips or sheets of fascia tissue can be utilized in this way is surprising. The list includes the bridging of gaps in tendons by a tube of fascia sutured over the stumps, correction of paralysis of the eyelids and other muscles of the face, correction of flat-foot and habitual dislocation of the knee-joint and shoulder, fixation of kidneys and testicles and the use of the fascia rings to close the lumen of the intestine or correct prolapse of the rectum, and to serve as suture material. The list of uses to which sheets of fascia have been applied includes all kinds of hernia

operations, covering defects in the pleura, dura and in hollow organs, arresting hemorrhage in parenchymatous organs, in reenforcing the walls of vessels inclined to aneurysm, curing stiff joints, covering the stump after an amputation, and isolating a certain segment of a peripheral nerve. Kirschner states that no damage from the use of the fascia has been noticed in any instance, and in many cases it permitted operations absolutely impossible with any other material or method. He concludes his long article with the literature on the subject.

99. **Operative Treatment of Hemoptysis.**—Lischkiewitsch states that the intervals since up to five years in his twelve cases testify to the advantages in certain cases of rebellious hemoptysis of measures to compress the lung, and especially what he calls thoracoplastic pleuropneumolysis. *None of the patients have had any hemorrhage from the lungs since, nor any of the eleven operated on since 1911.*

112 *Holmes and Semmelweis. P. Richter.

101. **Duodenal Ulcer.**—Ewald has encountered in the last three and a half years 532 cases of gastric and eighty-two of duodenal ulcer. He found blood in the stools the most constant sign of the latter; it was present in every case with one exception, but not always at the first examination. He declares that about 50 per cent. of all duodenal ulcers are amenable to medical treatment. On the other hand, operative treatment has its drawbacks; in one case the patient had a severe hemorrhage from the duodenal ulcer two months after it had been treated by gastro-enterostomy. He advised an operation only in eighteen of his eighty-two cases.

102. **Adhesive Pericarditis.**—Tornai calls attention to a symptom of adhesive pericarditis which he noticed very pronounced in a case described in detail. Just over the center of the left costal arch the wall sank in during inspiration over an area as large as one's hand. This circumscribed sinking in of the wall showed *pronounced pulsation* in this case, but in certain others the pulsation did not become evident until the patient drew a deep breath. Retraction of the chest wall is not pathognomonic, as pleuritic adhesions may cause this funnel-shape of the chest during inspiration. But when the retraction is thus *circumscribed* along the left costal arch, between the parasternal and anterior axilla lines, and it pulsates, he regards it as pathognomonic of adhesive pericarditis. The pulsation is synchronous with the carotid pulse. The best way to examine for retraction of the wall is to lay one hand on the lower part of the sternum, the other hand on the spine opposite; then as the patient takes a deep breath we can feel that the chest grows narrower between our hands, and we can perceive the characteristic pulsation, the systolic retraction, much more distinctly than with simple palpation. The preference of the edema for the upper part of the body is also characteristic. Still another sign is the paradoxic engorgement of the veins in the neck during inspiration; they may show plainer during inspiration than at other times. He thinks that tuberculosis is frequently involved in the production of adhesive pericarditis. Roentgenoscopy may show that the entire heart moves with the excursions of the diaphragm.

112. **Holmes and Semmelweis.**—Richter states that not only Holmes but others before Semmelweis had established the transmissibility of puerperal fever, but Semmelweis' great work lies in his insisting that puerperal fever is not a mysterious *infection* but is the work of every-day germs, and that he did not restrict himself to theorizing but put his conceptions into actual practice in the face of immense opposition.

Deutsche medizinische Wochenschrift, Berlin

sung.) Lonhard.
117 Differential Diagnosis of Echinococcus Disease of the Lung. Guischard.
118 Chemistry of the Protoplasm and Cell Nucleus. O. Gans.

113. **Local Treatment of Contact Ulceration Following Intubation.**—Bokay states that 69.86 per cent. recovered of the 657 children with laryngeal diphtheria in his service since 1900 requiring intubation. He never did primary tracheotomy, but *secondary tracheotomy became necessary in thirty-one* cases. In fifty-one cases the throat ulcerated under the tube, but this healed in all under local treatment with alum applied on O'Dwyer's special tube made with a low retaining swell, coated with gelatin mixed with alum. The regular ebonite tube had been *in place for from sixty to 294 hours in these* cases, but the decubitus healed under the medicated tube in an average of 113 hours. In twenty-one other cases secondary tracheotomy became necessary in spite of the medicated tube and eleven of the group recovered. Bokay quotes Shurley's *similar favorable* experience with tubes coated with saturated alum (The Journal, 1912, lix, 1123), and mentions some German clinicians who have also used the medicated post-intubation tubes. If O'Dwyer's directions are scrupulously followed, he says, the results are invariably excellent.

114. **Nature of Diabetes.**—Frank writes from Minkowski's clinic to suggest that diabetes may be regarded as the pathology of glycogen. Cohn presents evidence to show that in diabetes the salt *metabolism* is abnormal in that there is a deficiency in sodium and an excess of potassium. The cause of this disturbance is defective functioning on the part of glands, the pancreas in particular, which are storers-up of potassium. Treatment should aim to restore the normal balance between these salts. This has been empirically done by giving oatmeal to diabetics. Oatmeal ash contains 4.30 per cent. sodium to 23.73 per cent, potassium, while *wheat* flour has respectively 0.76 and 34.43 per cent., and rye flour 1.75 and 38.44 per cent. The proportion of sodium to potassium in oatmeal is thus 1 to 5.5 while with wheat flour it is 1 to 45 —a difference enough to explain the benefit derived from oatmeal in diabetes.

Cohn has previously presented evidence to the effect that an important contributing factor in gout is likewise a disturbance in the metabolism of sodium and potassium. In gout, however, *it is the* sodium *proportion* that is *abnormally* large and the *potassium* abnormally low—just the reverse of what he has found to be the case *in* diabetes. The organ in charge of the reserves of potassium, the pancreas, has become functionally incompetent, and potassium should be systematically administered. Among the facts he cites to sustain *this* theory is his finding that the blood in the pancreatic artery, thus entering the pancreas, contained an average of 0.108 per cent. sodium to 0.014 potassium; the blood in the pancreatic vein, on the other hand, just emerging from the pancreas, contained only 0 094 *per cent.* sodium to 0.027 *per* cent. potassium.

To the objection that the total proportion *of the* salt in the *body* is so small as to be negligible, he replies that recent research has demonstrated the unsuspected importance of even minute proportions of certain *cell constituents*—even a single ion may in some circumstances decide the life or death of the cell. He enumerates as follows the points which speak in favor of the assumption that the diabetic is *suffering from* an excess of potassium and lack of sodium: (1) the frequent occurrence of free uric acid in the urine; (2) Rumpf and Dennstedt's finding of 0.2 sodium to 4.1 potassium in the ash of a diabetic's liver when normally both are about 1.5; similar findings were encountered in numbers of others; (3) accelerated ferment activity of the pancreas enzyme in contact with potassium salts; (4) the close resemblance between the symptoms of potassium poisoning and those of diabetes, especially the development of glycosuria after augmented intake of sodium; (5) increased potassium content of the urine in diabetics; (6) the resemblance between diabetic coma and the heart failure in potassium poisoning, and (7) Loewi's recent experiments with animals rendered diabetic showing that the diabetic heart muscle is extraordinarily sensitive to potassium. Cohn says in conclusion *that his encouraging* clinical experience with treatment on this basis has also confirmed the correctness of his premises.

130 *Determination of Ammonia in the Urine.* (Zur Abkürzung der Ammoniakbestimmung im Urin nach Krüger-Reich-Schittenhelm.) A. Hahn.

129. **Insomnia.**—Ebstein reiterates that during the waking hours the supply of blood to the head is controlled by the erect position but on reclining, gravity aids in keeping the brain unusually well supplied with blood. This of course is liable to prevent sleep, and he thinks that measures may be devised which will counteract this to some extent. The blood in the arms—as the arms usually lie in bed—meets and combats the blood flowing from the brain, the stronger stream from the arms choking back the stream of blood coming from the brain. To counteract this, he advises a patient *inclined to* sleeplessness to grasp with his hands the head of the bed about eight inches above the pillow. If there is nothing there that can be grasped, a towel can be tied tight across which the hands can seize not lower than eight inches above the pillow. The body is slipped down in the bed so that the arms are thus held sloping upward above the head. By this means the blood-stream flowing down from the arms, with the velocity of the greater drop, helps to aspirate the blood from the brain instead of fighting against it. When the position becomes too wearisome, the wish to change the position must be combated *at first. Only when the desire* becomes imperative is it abandoned and the body turned with as little effort as possible into the attitude in which one habitually drops to sleep.

144 Determination of the Blood-Pressure. (Blutdruck und *Blutdruckmessung.)* L. Saathoff.

134. ***Jaundice in the New-Born.**—Ylppö* has worked out a method for studying the secretion of bile pigments in the fetus, etc., and states that the fetal liver allows bile pigments to pass into the blood. Icterus neonatorum is consequently a physiologic and uniform phenomenon, although at times it may reach a pathologic intensity.

136. **The Abderhalden Test in Diagnosis of Gastro-Intestinal Trouble.**—Kabanow states that he has applied the test with preparations made from various portions of the gastro-intestinal tract, portions which seem to be physiologically and anatomically independent of each other. He thus applied the test with preparations made separately from the fundus, the pylorus, the duodenum, small intestine, large intestine and appendix, and tabulates the details of sixteen cases. It is remarkable to note the positive reaction to the special organ tissue involved, and the lack of any reaction in presumably purely nervous affections. One table reports the *findings in* four cases of pernicious anemia; the reaction was positive to stomach and small intestine tissue in one case; to the latter alone in two others, and there was no reaction in the case of a patient who had entirely recovered from the anemia. The only contradictory finding was in a case of acute gastritis. The test was applied the third day and there was no reaction, evidently because the ferments had not yet had time to appear in the blood.

137. **Influence of Roentgen Rays on Growth of Plant and Animal Tissue.**—Schwarz reviews what has been done in this line to date, and gives an illustrated description of his own positive research with green beans exposed to the Roentgen rays from half a minute to five minutes and then planted. He aimed to keep the exposure at the lowest possible dosage to obtain an influence on growth. The results were so strikingly positive that he applied the same technic to granulating wounds, covering half the wound with a sheet of lead and exposing the other half at three or five day intervals to a soft tube of about 2 DMa for about five minutes at a distance of 30 cm. Similar experiments with the ears of rabbits confirmed the stimulating influence of the Roentgen rays on tissue growth.

138. **Improvised *Apparatus for Superheated Air.*—Schmerz** makes a cylinder or tunnel of chicken wire-fencing and winds it with a plaster bandage, coating it thick on both sides with plaster. He makes an inner screen in the same way, and introduces into the appliance a small stove-pipe. The same principle can be applied with cement. The apparatus thus made answers every purpose for the application of superheated air.

139. **Treatment and Prevention of Psychical Equivalents of Epilepsy.**—Heidenhain is convinced *that the* chief factor is a nervous contraction of the blood-vessels in certain parts of the brain. This can be combated by inhaling amyl nitrite, and he advises that persons inclined to epilepsy should carry constantly a small bottle of amyl nitrite on their persons

and at the first sign of trouble inhale a few drops poured into a cup or glass. The family might also be instructed to administer the amyl nitrite if the individual himself is not able to do it. Heidenhain has had two patients whom he was able to bring out of the recurring epileptic condition of imperfect perception and understanding (*Dämmerzustände*) by repeated inhalation of amyl nitrite. Migraine is also frequently amenable to inhalation of amyl nitrite as this, too, is traceable to cramp of the vessels in the brain. He says that amyl nitrite is so simple and harmless that epileptics should be encouraged to use it more, even between attacks.

142. **Abderhalden's Test in Disease of the Thyroid.**—Lampé and Fuchs applied this test in sixty cases of abnormal thyroid functioning and they found that serum from patients with exophthalmic goiter or basedowoid induced a constant positive reaction with tissue from the thyroid of a person with exophthalmic goiter. In a few instances their serum digested also thymus and ovary or testicle tissue. The serum of the myxedematous had likewise the power to disintegrate ordinary thyroid tissue. This was also the case with serum from patients with endemic goiter. The ferments elaborated in these conditions seem to be specific to an extreme degree.

151 *Syndrome from Functional Adrenal Insufficiency. (Bradykardie, Hypotonie, niedere Körpertemperatur, eigenartige Muskelschwäche, Neigung zu Ohnmachten.) E. Hoke.

148. **Hemolytic Anemia from Congestion in the Spleen.**—Pribram reports extensive research on dogs which showed that urobilinuria could be readily induced by causing congestion in the spleen; the appearance of urobilin in the urine is the only sign known to date indicating abnormally increased destruction of blood-corpuscles. It proved impossible to induce the urobilinuria in other ways, not even by intravenous injection of substances known to be directly destructive to the blood. Further experiments showed that stasis in the inferior vena cava, such as occurs with uncompensated valvular lesions, leads to urobilinuria to an intense degree. He has never encountered a clinical case of isolated stasis in the spleen with exaggerated destruction of red corpuscles and consecutive anemia and urobilinuria, but a number of such cases have been described in the literature. All the patients had varicose enlargement of the splenic vein and its branches and their course was extremely tortuous; sometimes the vein was kinked and actual varicose tumors developed in the hilus of the spleen. The spleen was always much enlarged but generally there were no other pathologic findings except possibly slight cirrhosis of the liver, but all the patients showed signs of *abnormal destruction of* blood, anemia and urobilinuria. The most remarkable feature in the cases is that the patients are young and the vascular apparatus elsewhere seems normal. Pribram thinks that this syndrome of varices in the splenic vein with extreme congestion in the spleen and destruction of the reds must be regarded as a special affection *sui generis.* He regards the sclerosis and varicose enlargement of the vein as the primary trouble, and suggests that this peculiar pathologic condition of the veins in this region may be traced to an infectious process in the umbilicus in the first weeks of life. There was a history of such a process in two of Türck's patients. Several of the cases on record were in children. There is also the possibility of injury from toxic products formed in the intestines which are liable to act most intensely on the nearest veins, namely, the portal system; Stahl used to say "the portal vein is the portal of ills."

149. **Diphtheria Bacilli-Carriers.**—Markl and Pollak report from Trieste that they found extremely virulent diphtheria bacilli in the nasopharyngeal secretions of four out of ninety-one healthy persons examined free from known contact with diphtheria. In six other cases bacilli were found which apparently could be distinguished from true diphtheria bacilli only by their lack of virulence. The tellurium plate proved most reliable for cultivating the bacilli, but they state that none of the usual morphologic differential criteria are *absolutely* dependable.

151. **Asthenia from Functional Insufficiency of the Adrenals.**—Hoke reports a case which, he says, belongs in the same category with the cases of a peculiar state of asthenia of short duration reported by Riesman in The Journal, 1912, lviii, 1846. His patient was a woman of 32 who had never been quite healthy since a severe diphtheria at 14. She tired easily and had palpitations, dizziness and sudden sweating on slight exertion. At 28 she passed through a normal pregnancy. Hoke was called to her as she was said to have fainted. He found the skin pallid and clammy, the pulse scarcely perceptible; the heart rate 52 but rhythmic; the heart sounds pure; the temperature in the mouth 35.8 C. The patient felt that she was dying. He injected 0.5 c.c. of 1 to 1.000 epinephrin solution, assuming that the trouble was an acute vascular paralysis. The effect was surprising; in fifteen minutes the symptoms had subsided, and the patient felt well and strong; pulse 62, and much stronger. She was then given a course of carbonated baths and now seems to be permanently improved; the myasthenia is much better, the pulse up to 72, and the blood-pressure up to 110.

157. Serotherapy in Pregnancy Intoxication.—Freund gives the details of the cases of pregnancy dermatitis on record, and describes three from his own experience in all of which serum therapy was applied; also several cases of hyperemesis, and three cases each from the literature and from his own experience in which serotherapy was applied in eclampsia. He then records similarly the experience to date with normal horse serum applied in pregnancy dermatitis, uncontrollable vomiting and eclampsia, and further similar records of cases in which Ringer's solution was applied. The latter group includes nine dermatitis cases from his own experience, and two of hyperemesis. The total material is classified for comparison of the effects of these various forms of serotherapy. The most favorable results were obtained in pregnancy dermatitis; thirteen patients were cured with serum from pregnant women, four with horse serum, and fourteen with Ringer's solution. In only one case of pregnancy dermatitis was no benefit derived. No effect was apparent also in two of the ten cases of uncontrollable vomiting. Two patients died of the twelve with eclampsia given serotherapy; the others recovered. The practical conclusions from the above figures are emphatically in favor of treating all patients with pregnancy dermatitis or uncontrollable vomiting by subcutaneous infusion of 200 c.c. of Ringer's or Locke's solution, repeating the infusion two or three times at need. If this fails, a subcutaneous or intravenous infusion of 20 c.c. of horse or human serum should be given. Whether serotherapy should be applied in eclampsia is still an open question, as the course of eclampsia is so exceptionally acute; but the results observed to date justify its tentative use.

Freund traces the history of serotherapy, remarking in conclusion that the favorable practical results obtained in the toxic conditions for which a pregnancy is responsible, are the outcome of long years of research based on the placenta theory. This led to the discovery of the binding of the toxic substances in the placenta by fresh serum. Then followed the era of serotherapy of toxicoses, and this in turn has yielded to the treatment of toxicoses by solutions of salts resembling serum in their composition. This is much simpler and more convenient than serum itself. It is possible, he adds, that administration of calcium and potassium salts might be useful during a pregnancy for prophylaxis of toxic conditions. The formula he prefers for the Ringer's solution is 7.5 parts sodium chlorid; 0.1 part potassium chlorid; 0.2 part calcium chlorid and distilled water to 1,000 parts. Seventeen of the total forty-nine cases analyzed are from his own experience at the Berlin Charité hospital.

159. Factors Predisposing to Cancer.—Hansemann emphasizes that it is possible to steer clear of many forms of injury, which are liable to become subject later to cancerous degeneration. Other injuries cause lesions which can be excised in time. In still others the primary injury is not known, and this gap in our knowledge can be filled only by long years of observation of patients developing cancer later, and hence science can look for the solution of these problems only to the family physician or to physicians making a study of their own bodies, and keeping a record of all injuries, etc.

Of the precancer affections, he regards pigmented xeroderma as the most typical as this is familial, indicating a congenital predisposition, and malignant degeneration may occur even in children. Sunlight here is the irritant involved, but once the affection is installed, artificial light may suffice for the irritant. He thinks that a number of other skin affections belong in this predisposing-to-cancer category. Leg ulcer is an example of an acquired predisposition; when such an ulcer has persisted for years, it is often possible to discover cancerous degeneration at some point; this occurs far more frequently than is generally recognized. The greater the predisposition, the less irritation is required to elicit cancer growth. Only very rarely is the predisposition so great that the irritation causes the cancer to develop in a short time; decades are required for this, as a rule, and this explains why cancer is most frequent between 40 and 60. Those who escape to 60, show that they have no predisposition. The successful excision of cancer testifies further that the predisposition is local. Aberrant embryonal tissue seems to be especially dangerous; Hansemann has never known of an instance of malignant degeneration of an ordinary wart on the skin or in the larynx. The warts, etc., that turn into cancers are always congenital.

He insists that more attention should be paid from the standpoint of prophylaxis of cancer to hemorrhoids and fistulas, to constipation as a source of irritation of the large intestine liable to lead to cancer, irritation of the esophagus from peppery food and strong liquors, and irritation of the stomach from burning hot food. He states that the stomach mucosa does not feel heat and consequently when one takes an overhot mouthful and swallows it quickly, no further discomfort is felt from it, and yet the stomach mucosa is injured more readily by hot substances than the mucosa lining the mouth and esophagus. This is particularly liable to be the case if the extra hot mouthful happens to be meat or potato; this holds the heat at one point and it is not spread as in case of a hot fluid. The hot chunk lying at one point is almost certain to injure the mucosa seriously and there can be no doubt that this has contributed to ulcer in the stomach in certain cases.

168. Postoperative Disturbances.—Linkenkeld warns that it is necessary to ascertain whether there are not metastasic nodules in the peritoneum, too small to be palpated and yet showing the hopelessness of any operation. This is particularly to be guarded against with cancer in the kidney or rectum, and he advises an exploratory laparotomy. In two such cases he found the peritoneum studded with metastases and realized the inoperability of the growth which nothing else had indicated. He thinks that adhesions have been regarded too seriously in the past; trouble need not be anticipated from them as a rule, except when they are liable to bind some part of the stomach or intestines or drag the mesentery.

The whole secret of avoiding postoperative disturbances, he reiterates, is in correct diagnosis and operating only when absolutely necessary. The simultaneous occurrence of two or more surgical affections is often perplexing: in one such case he found epigastric hernia, empyema of the gall-bladder and ulcerative appendicitis. In another, empyema of the gall-bladder with kidney-stone colic; one woman with gonorrheal salpingitis and recurring appendicitis was treated by appendectomy alone, and the gynecologic affection healed spontaneously. He warns further that certain pains cannot be referred to certain pathologic conditions found, as, for example, intense pain in the sacral plexus cannot be explained by retroversion of the uterus.

Pain from inflammation of an abdominal organ does not let up during sleep; it is increased by movements; the organ feels warmer than usual, the arteries pulsating more actively; the sensitiveness of the abdominal wall to pressure is diffuse, and the sensitiveness increases as the pressure is relaxed. With hyperesthesia, there is not this diffuse character of the sensitiveness; the tender points characteristic of neuralgia can be detected; the pains are intermittent and do not disturb the sleep and they are not exaggerated by movements but can be modified by emotions, especially pleasurable ones, and by diverting the attention. On palpation of the *internal* genitals the patient jumps but if the internal genitals were actually inflamed proportional to this extreme tenderness, the patient would not be well enough to come to the office.

He mentions also that lumbago and spondylitis are often erroneously diagnosed as perimetritis. Intermittent, laborlike pains indicate that a hollow organ is trying to expel something through a narrow portion of the organ. A tuberculous ileocecal tumor often proves misleading in this way; if large enough to be palpated it is assumed to be a genital tumor. He diagnosed a tuberculous ileocecal tumor in a woman with intense *intermittent pains in the cecal region* and a palpable tumor during the attacks, but the trouble proved to be spasms of tabetic origin. *Intermittent pains* are also liable in case of sclerosis of the mesenteric vessels; the picture is similar to that of intermittent claudication. These cases are often wildly misleading.

He adds that the sudden cessation of stormy labor-pains is a sign that the uterus has ruptured, and the subsidence of the intense pains with a ruptured tubal pregnancy is a sign that the hemorrhage has been arrested. Tenderness at the three typical painful points of the ileo-inguinal nerve is frequently a sign of coitus interruptus; the uterus and adnexa are generally tender on palpation and there is usually some discharge from the uterus. In conclusion, Linkenkeld remarks that it does not redound to the credit of the profession when the lay public recognize fashions in medicine, saying, for example, "Nowadays everything is ascribed to appendicitis."

176. Influence of Castration on the Growth of the Bones.—Sellheim has continued his research in this line and here gives an illustrated description of experiments with the male of the deer in which the effect of castration on the growth of the branching horns could be instructively studied. The facts observed suggest that osteomalacia may be regarded as a pathologic exaggeration of a natural physiologic process in pregnancy. It aims to supply the needs of the fetus while sparing the mother's bone system. Rachitis must also be regarded from the same point of view. Castration arrests the exaggerated ovarian functioning, and in rachitis the aim should be to over-dominate the injurious internal secretion by supplying artificially the antagonist secretion, which, in this case, he thinks, is the hypophysis secretion. Two articles have been published recently advocating the use of hypophysis extract in treatment of rachitis (Klotz and Weiss).

184. The Colloids in the Urine as Factor in Production of Calculi.—Posner remarks that courses of mineral waters dilute the urine and thus counteract the concrement-producing action of the colloids in the urine. They are also liable to modify the crystal-producing property of the urine and, by promoting diuresis, to wash out sediment.

Lichtwitz incriminates likewise the colloids and states that therapeutics must aim to provide protecting elements in the urine, such as gelatin, or give salts to enhance the solubility of the colloids.

201 Present Status of Cancer Research. (Den komparativa och experimentella kräftforskningens problem.) L. Wolff.

200. Local Diagnosis of Spinal Cord Tumors.—Söderbergh analyzes a few cases from his own experience with diagrams showing the significance of the findings. In one case there were three tumors in the spinal cord; the findings in this and the other cases indicate, he thinks, that the seventh dorsal nerve innervates the upper part of the external abdominal oblique; the eighth and ninth dorsal nerves the transverse or transverse plus external and internal oblique muscles, while the tenth innervates mainly the internal oblique. In the above case the abdominal wall was almost as hard as with a newly perforated gastric ulcer. The cramps subsided only for a few minutes at a time, but the pain had paroxysmal exacerbations. No abdominal reflexes could be elicited. During coughing the abdominal wall was drawn up in the epigastrium a little to the right, while below the umbilicus the position was unmodified. Electric tests showed reduced irritability of the upper part of the left external oblique and the patient complained of pain in this region. Söderbergh accepted these slight findings as indicating a tumor at the left seventh dorsal root, compressing the spinal cord and responsible for the spastic paresis in the legs with recurring paroxysms of pain, the bladder disturbances and sensory symptoms corresponding to the tenth dorsal root. The operation revealed a psammoma 22x10 mm. at the seventh dorsal nerve. Improvement followed its removal but the paroxysms of pain returned later and during them the umbilicus was drawn up to the left. As the cramp relaxed, the umbilicus did not return to normal condition but moved up toward the right, and if the patient coughed this displacement became more noticeable. A second operation revealed a second tumor, compressing the twelfth dorsal segment and a third operation became necessary for still another tumor. The patient was a woman of 48. In another case the tumor was in the upper cervical region and had grown into the dura. In the two other successful cases the tumor was also in the upper cervical region in one and in the cauda in the other. All were thus rare types. A diagram and table give other instructive data.

THE PROTEIN POISON AND ITS RELATION TO DISEASE *

VICTOR C. VAUGHAN, M.D.
ANN ARBOR, MICH.

In 1903, Vaughan and Wheeler found that the cellular substance of the colon bacillus contains a highly active poison. This was obtained by extracting the dried, dead cells with a 2 per cent. solution of sodium hydroxid in absolute alcohol at 78 C. (172.4 F.). This poison was partially purified by repeated precipitation from alcoholic solution with either mercuric or cupric chlorid and removal of the base with hydrogen sulphid. This poison kills guinea-pigs when injected intravenously in doses of 0.5 mg. When given intra-abdominally this dose must be multiplied by 16 and when given subcutaneously by 32 in order to cause death.

Subsequently the same, or a closely related, poison was obtained from other pathogenic and from nonpathogenic bacteria, and then from vegetable and animal proteins. This work has been repeated and confirmed by others in this country and abroad. It is now known as "the protein poison" and is believed to be a constituent of every true protein whatever be its source. The purest proteins known, such as edestin from hemp-seed and zein from corn-meal yield this poison. It is not found in certain albuminoid substances, such as gelatin. It is found in Witte's and De Chapateau's peptones, but not in that of Defresne. Whether or not the latter is prepared from gelatin is not known.

The symptoms induced by this poison are quite characteristic and can be divided into three well-defined stages. The first is that of peripheral irritation and is marked in the guinea-pig by attempts to scratch every part of the body. In man it is shown by an urticarial rash which spreads from the point of injection and may extend to every part of the skin and invade the visible mucous surfaces. The second stage is one of partial paralysis with rapid and shallow breathing. The third stage is known as the convulsive, and begins in isolated clonic movements which become more frequent and general, finally involving all the muscles of the body and terminating, as a rule, in death. With fatal or nearly fatal doses there is a fall in temperature, which with fatal doses is progressive, and the temperature may fall in guinea-pigs to 85 F. before death. When recovery occurs, the first symptom of this is a return of the temperature toward the normal. In both man and experimental animals, recovery from a single nonfatal dose is speedy, and a complete return to the normal condition may result within a few hours.

Small doses of this poison administered subcutaneously cause fever, and a like effect can be induced with unbroken proteins. By changing the size of the dose and the intervals of administration it is possible to induce any and every known type of fever in experimental animals. One can induce an acute fever, terminating fatally, in a few hours. In this type the temperature can be carried to 107 F., which seems to be near the thermal death-point in these animals. Intermittent and remittent fevers are easily established and varied at the will of the experimenter. A prolonged fever extending through weeks and with a chart not distinguishable from one of typhoid may be established and carried to a fatal issue in rabbits. In fever of this kind there is the usual morning recession and the afternoon exacerbation so characteristic of typhoid. Furthermore, there is increased nitrogen elimination, and progressive emaciation is observed.

When proteins are taken into the alimentary canal and are acted on by the digestive juices the product becomes poisonous at about the peptone stage, and if the peptone formed in alimentary digestion should be absorbed into the circulation it would be highly injurious; but the digestive process proceeds and the peptone is broken up into harmless amino-acids, which are absorbed and synthesized into the proteins of our bodies.

When proteins find their way into the blood without being brought under the action of the digestive juices of the alimentary canal they must be digested in the blood and tissues, and in this process the protein poison is set free and, since general distribution cannot be hindered, it exerts its deleterious effects on the body.

We now know that the symptoms of many diseases are due to the parenteral digestion of proteins. Whenever a foreign protein, be it particulate or in solution, alive or dead, gets into the blood and tissue it must be disposed of by parenteral digestion. There seems to be no great differences in the amount of poison contained in the molecules of ordinary proteins, whether they be vegetable or animal, and, as has been said, the action of the poison is the same whatever the protein from which it has come. Dead protein contains just as much poison as living protein, but if the latter can grow and multiply in the body it increases the amount of its poison. Quite naturally most of the foreign proteins that find their way into the blood are living, such as bacteria and protozoa. Researches into the poisonous action of ordinary proteins, however, under the influence of the condition of sensitization, have demonstrated that living proteins are not absolutely essential to the development of certain diseases. If in any way proteins find access to the blood and tissues and the body becomes sensitized, then disease and death may result without bacteria or protozoa playing any part in the process. It has been shown quite conclusively that hay-fever and kindred

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

disorders are due to sensitization to the pollen of diverse plants. Horse-asthma comes from the inhalation of hairs, and possibly of other proteins, from the horse carried through the air in other forms. The inhalation of peptone or other finely divided proteins may cause acute and subacute inflammation of the upper air-passages. Sensitization may result from the absorption of undigested or partly digested proteins from the alimentary tract. Whether or not the summer diarrheas of infancy ever originate in this way is a question to which a positive answer cannot yet be given. There are some good reasons for suspecting that the lowered vitality of the infant by excessive heat may lead to absorption of undigested proteins, and in this way cholera infantum and kindred diseases may be induced. We have not enough information on this matter at present, however, to enable us to speak positively, and I shall confine myself to a brief statement of the part played by the protein poison in the bacterial diseases. Recent studies in protein sensitization have quite materially modified our views concerning the nature and progress of the infectious diseases.

Bacteria have generally been regarded as unicellular plant organisms. This view is without just warrant. There is no proof that the bacterial cell contains cellulose. Indeed, all the evidence that we have concerning the chemistry of the bacterial cell is quite to the contrary. The bacteria which have been most thoroughly studied consist largely, if not wholly, of nucleoproteins or glyconucleoproteins, and are therefore more closely related to animal than to vegetable forms of life.

It has been assumed, furthermore, that the chemical structure of the bacterial cell is relatively simple. This has been shown not to be true. The molecules which make up the greater part of the proteins of the bacterial cell are quite as complicated as those that are found in the cells of our own bodies. These molecules contain at least two carbohydrates, one of which is attached to the nuclein group, while the position of the other has not been determined; but the weight of evidence is that it is a constituent of the protein part. Bacterial cell-substance yields the nuclein bases, and the greater part of it consists of protein, as is shown by its abundant yield of amino-acids, both mono and diamino. It will be seen from this that, although bacteria may be morphologically simple and without marked differentiation in structure, they are chemically quite complex and highly organized. This means that functionally they are quite on a par with the cells of the animal body with which the pathogenic bacteria so often compete.

The newer theory of how bacteria cause disease may be stated as follows: The cell is the morphologic unit of life, though not the physiologic unit. The latter is the protein molecule which lies in the cell and of which the cell is essentially composed. Bacteria are particulate proteins, and viruses capable of causing disease may be without form recognizable by us. The only essential and constant distinction between living and dead matter is that the former is never in a state of equilibrium; it is constantly absorbing and excreting; it feeds and eliminates; it is constantly trading in energy; it is labile, not stable. Every living cell must form ferments by which it splits up the pabulum on which it feeds. Whether a given bacterium is pathogenic to a given animal or not depends on two things. First, in order to be pathogenic it must be able to split up and feed on the proteins of the animal body; otherwise it cannot grow and multiply in that animal's body and consequently cannot harm it. Secondly, the ferments of the cells of the animal's body must not be immediately, at least, destructive to the invading bacterium. When the ferments of the body-cells have this destructive action on the bacterium, the latter cannot be harmful to the former. These two things determine the pathogenicity or non-pathogenicity of a bacterium, and one or the other or both lie at the base of all bacterial susceptibility and immunity. The pathogenicity of a bacterium is not determined by its capability of forming a poison, because there is no protein without poisonous content. The ferments with which cells, be they bacterial or body cells, split up their pabulum or prepare their food are known as extracellular ferments. They diffuse from the cell into the surrounding medium, and exert a cleavage action on those food substances which they are capable of thus altering. Some are highly diffusible and may pass through a relatively large amount of pabulum, while others apparently act only on those substances that come into contact with the cell.

Of all the bacteria with which we have worked the *Bacillus prodigiosus* yields the largest amount of the protein poison, but this organism is not pathogenic to man or laboratory animals because it cannot grow and multiply in the animal body. On the other hand, the anthrax bacillus yields a relatively small amount of the protein poison, and yet it is one of the most infectious organisms because it can grow and multiply in the animal body.

The extracellular ferments are not the only ferments with which living cells are supplied. Many, probably all, living cells have intracellular ferments, which are non-diffusible and remain within the cell. The function of these is to take the food as prepared by the extracellular ferments and build it into the cell tissue. It will be seen that the extracellular ferment is destructive or analytic in its processes, while the intracellular ferment is constructive or synthetic.

The important lesson which we have learned from our studies of protein sensitization is that the nature and action of cell ferments may be, to some extent at least, modified at will. Cells can be trained or educated to pour out a special ferment to digest a specific body. This is the explanation of vaccination. The virus of small-pox is pathogenic to the unvaccinated, but is non-pathogenic to the man who has had the disease or has been vaccinated. The typhoid bacillus is no longer infectious to the man who has been properly vaccinated against this disease. Vaccination is secured by introducing into the body that protein which causes the disease, but in a condition so modified that it will no longer cause the disease, but will lead the body-cells to pour out a ferment which will destroy that specific protein when it is reintroduced. In vaccination for small-pox the protein has been modified by being passed through the cow. A vaccine for anthrax is obtained by growing the bacillus at a high temperature or in the presence of a weak germicide. The dead typhoid bacillus serves as a vaccine. When an individual has been protected by one of these vaccines and is exposed to the disease, the organism is destroyed so soon after admission to the body that it does no harm, and in this way immunity is secured by vaccination. It is easily understood that this form of immunity is not absolute, but is relative, and may be overcome by severe or prolonged exposure.

Vaccines are now used not only as preventive but also as curative agents. Much harm is being done by their indiscriminate and ignorant employment, but their proper use is rational and scientific. They are of special value in local infections, and they operate by stimulating a wide area of body-cells to furnish a ferment which destroys the bacterium that is the cause of the local condition.

In the light of what has been learned from studies of the protein poison and protein sensitization let us see how the typhoid bacillus acts in inducing the disease. The bacillus finding its way into the body grows and multiplies. Its extracellular ferment acts on the proteins of man's body and prepares the food which is built into typhoid tissue by the intracellular ferments. The ferments of the body-cells are not capable of destroying the invading organism and during the period of incubation it multiplies greatly. During this time the man is not ill. It is not, therefore, the growth and multiplication of the bacillus in the man's body that directly causes the symptoms of typhoid fever, because at the time of its most active growth there is no fever or other symptom. During the period of incubation the bacillus furnishes the ferment, and the proteins of the man's body constitute the substrate. These proteins without much change are taken into the bacterial cells and built into typhoid bacterial tissue. The process is largely one of assimilation and construction, and no poison is liberated; consequently there is no fever or other symptom. After about ten days the period of incubation ceases and the disease is ushered in. The body-cells, under the influence of the foreign protein and for the purpose of its destruction, begin to pour out a new specific ferment. During the disease the body-cells furnish the ferment, and bacterial cells constitute the substrate, the process is destructive, the protein poison is liberated and fever with its concomitants result. The person may die as a result of the too rapid liberation of the poison, from a lesion due to the effects of the products of the parenteral digestion or from chronic poisoning.

221 South State Street.

ABSTRACT OF DISCUSSION

Dr. John Zahorsky, St. Louis: It is refreshing to pediatrists to find that many American pediatrists and physicians have rather held to the original view that, after all, it is the protein that causes the death of the babies in summer diarrheas. Holt of New York has held the same view. There are certain forms of diarrhea in children that are not bacterial. I think that this is now generally recognized. The method by which this poison is produced, how it enters the blood and what circumstances produce it, is yet to be worked out. These diarrheas occur early in the summer. The condition is ordinarily called fermentative diarrhea. It is attributed to carbohydrate fermentation. While we have acute attacks of indigestion in the winter, due to acute indigestion of sugar, in the summer we have diarrheas which we cannot cure by giving the various treatments. The diarrhea is persistent, sometimes for weeks; that type of disease, the toxin of which is unknown, is probably not a direct infection, but undoubtedly depends on some poison, as suggested by Dr. Vaughan.

Dr. Mary Strong, Omaha: I want to speak from the clinical point of view. In Omaha the climate is abominable in summer. Some ten years ago a healthy, live baby was born under my service. I saw that baby when it was about three days old, and for no reason that we could discover it was almost comatose, with a temperature of over 104 F. I did not have laboratory methods convenient for use. I used common sense. I had the baby stripped and sponged with cold water; cold water was injected into its rectum, and we gave it all the cold water that it would swallow; the baby promptly recovered without any change of food. It was having mother's milk, which was good. I know now why that baby recovered. Since then, every summer I have seen babies in Omaha dressed according to the directions of the Eastern doctors, with flannel next to the skin. My first treatment is to take off every scrap of flannel. I think that the nearer naked the baby is in hot weather the better. I saw a baby in my office last summer with a high fever and acute diarrhea, dressed according to Holt. It was not dressed that way when it left my office. It had on one necessary garment and a slip—and I told the mother to take that off when she reached home. The baby recovered. I believe that I know now why it recovered. I found out several years ago that clothes kill a great many babies in the summer time, particularly flannel. It makes them so warm that changes take place in the digestive juices.

Dr. C. H. Johnson, Grand Rapids, Mich.: Finkelstein has reduced the mortality in his institution from 60 or 80 to 7 per cent. by cutting out sugar and salt in a large degree. He agrees with everything else that Dr. Vaughan says. Finkelstein says that the death-rate in diarrhea has not been reduced by the sterilization of milk. He believes that the disease is due to chemical changes.

Dr. C. G. Grulee, Chicago: It seems to me that there is another side to this proposition—the prime factor, the one thing necessary for such a theory to be realized—that this protein must be absorbed through a deranged gut. What causes the derangement? In answer to Dr. Johnson, I may say that Dr. Finkelstein's ideas have received a serious jolt in the last year. Bendix and Samelson have shown that the injection of sugar solutions made from freshly distilled water does not produce a rise in temperature when injected subcutaneously, while, if the distilled water used is old, a rise in temperature is produced. This, although not yet printed, has also been confirmed in Finkelstein's own clinic by a young Chicago physician, Dr. Grace Meigs, in regard to salts. This does not mean that we cannot produce a rise in temperature from the ingestion of salts or sugar by mouth. In fact, it has been shown definitely that those experiments are correct; that a certain amount of salt or sugar does cause a rise in temperature. The only way in which the seeming conflict of these two propositions can be explained is that the sodium salts or sugar, when given by mouth or rectum, causes a change which allows absorption of some product from the intestine and in that way produces a rise in temperature and symptoms. They have not determined the matter definitely, but have reason to believe that the product in the stale distilled water is not bacteria; but that does not make any difference, nor does it combat this theory of Dr. Vaughan's. It seems to me that, while there are many points that will have to be worked out, we may be on the right track in regard to the causation of summer diarrhea.

There is protein in the intestine other than casein, other than the protein ingested from food, which may be active in the mucus. This has not been accorded the place by pediatrists, which it perhaps deserves, as the source of putrefaction. This may cause a great deal of trouble. As we go further with Dr. Vaughan's idea, we may find that it is absorption of the mucus unchanged.

Dr. Louis Burckhardt, Indianapolis: Dr. Vaughan stated that some food is harmless at one temperature and harmful at another. In our city we have a first-class milk-supply. Our milk commission has controlled it. We have taken sample tests in the laboratories, and the last three tests came back with a count of three hundred. In spite of that, the board of health proposes to demand pasteurization of the milk. I am much interested to hear Dr. Vaughan's idea about the advisability of compulsory pasteurization of milk which has been produced under all the precautions.

Dr. H. W. Cheney, Chicago: Dr. Vaughan did not suggest it, but I wish to ask if this protein poison he speaks of is not the same as that present in horse-serum given therapeutically, which causes death in animals in which it is sometimes used. From a clinical point of view we can agree that some of the cases of summer diarrhea are caused by protein poison, but we know that a large proportion must be caused in other ways, because we can cure these patients feeding skimmed milk, a protein-rich food.

Dr. George S. Cattermole, Boulder, Colo.: In Colorado we have few cases of summer diarrhea. I believe the reason for this is our low mean summer temperature. Our nights are cool. Probably for this reason we are free from the intestinal disorders in infants that are so common in hot climates. So-called "cholera infantum" is almost never seen in Colorado.

Dr. T. C. McCleave, Berkeley, Cal.: I understood Dr. Vaughan to say that all protein poisoning is the same, the symptomatology depending on the localization in the body. In the exanthematous diseases, in which specific manifestations appear so largely in one organ, the skin, how does he explain the occurrence of the different characteristic eruptions under his theory?

Dr. Victor C. Vaughan, Ann Arbor, Mich.: It is evident that the presence of other constituents besides proteins in the food influences to a great extent the absorption of proteins from the intestines. This absorption is largely a question of osmosis. It is altogether probable that one dilution of sugar favors the passage of the protein into the blood, while another dilution would have the opposite effect.

I am glad that this question concerning scarlet fever was brought out. As I have stated, experimental fever can be induced in animals by the subcutaneous, intravenous and intra-abdominal injection of any kind of protein. These proteins have their predilection places in the body, where they accumulate. This is true of both living and dead proteins. The pneumococcus protein accumulates in the lungs; the typhoid protein in the mesenteric lymph-nodes and in the spleen, and the proteins which are concerned in the exanthematous diseases accumulate in the skin and submucous tissues. We have shown positively by experiments in the laboratory that white of egg injected into the circulation of a rabbit soon disappears from the blood. Later it may be found in various tissues. White of egg injected into a rabbit intravenously accumulates largely in the skin and in the walls of the intestines. It is also found in the kidneys. Not only does the foreign protein disappear from the blood and become diffused through the tissues, but it also carries with it an appreciable amount of the normal proteins of the blood. The symptoms of one disease differ from those of another largely on account of the organ in which the foreign protein is deposited and in which it is disrupted. The most skilful physician cannot distinguish by the symptoms alone between a meningitis caused by the meningococcus and one caused by the pneumococcus or a third caused by the typhoid bacillus. In all acute infectious diseases the poison formed is one and the same thing. It is the protein poison that kills in all these diseases.

The question has been asked concerning the pasteurization of milk. I should prefer to feed a baby on pure rather than on bad milk, on milk with a low bacterial count than on that with high bacterial count, even if the bacteria are not pathogenic. Bacteria, whether they are pathogenic or non-pathogenic, split up the proteins of milk and probably render them absorbable without complete digestion. The exact relation of cholera infantum and the other forms of summer diarrheas to anaphylaxis has not been made out with certainty. I am, however, of the opinion that the absorption of partly digested proteins has much to do with the summer diarrheas of infancy.

ACUTE ACID INTOXICATION IN CHILDREN *

THOMAS C. McCLEAVE, M.D.

BERKELEY, CAL.

This paper contains nothing new; but because the subject receives scant discussion in current text-books, and periodical literature contains articles dealing rather with particular aspects of the matter, it may be of some value to make a general survey of our knowledge of that important disorder occurring in children which, for want of a better term for the time being, we may still tentatively designate "acute acid intoxication."

Acid intoxication is an extremely common phenomenon in a variety of pathologic conditions, but in children, usually from 2 to 10 years old, we see very frequently a symptom-complex in which acidosis is a marked and constant characteristic. Attacks are commonly recurrent, and may come on suddenly or be preceded for a day or two by a prodromal period in which are observed listlessness, anorexia and coated tongue, and, quite strikingly, a bluish pallid ring around the mouth and beneath the eyes, with dusky cheeks. Headache may be complained of, and there is usually a coryza and injection of the conjunctivae, with a variable cough. Intense nervousness, even to marked meningismus, may be exhibited in the beginning, though always as the attack progresses, and frequently throughout, the child is apathetic and, in extreme cases, may even develop coma. In any but mild cases, the appearance of the child is indicative of serious illness. The face is pinched and pale, or often cyanotic, the eyes, at first bright, become sunken and dull, the lips are dry and cracked, the teeth covered with sordes, and the tongue dry and brown over the dorsum, with "strawberry" edges. The abdomen is retracted, and general wasting may be extreme. The skin is dry and harsh, often scaling after a severe attack.

The breath is foul, but the sweetish, fruity odor of acetone can always be detected, and frequently permeates the entire room in which the patient lies. There is always fever, the temperature rarely exceeding 102 or 103 F., but occasionally being very high. The pulse is soft, rapid and irregular, and the respirations sighing and irregular, often slow and deep, with marked "air hunger," both clinical and experimental evidence seeming to show that the acid poisons have a direct depressing effect on the vasomotor and respiratory centers.[1] I have seen two cases in which asthmatic manifestations were a prominent feature of the attacks.

There is no desire for food, and vomiting, except in the mildest cases, is always present, and often is extremely intractable. Large amounts of fluid may be vomited, and the rapid dehydration of the tissues occasions a most intense thirst, the child constantly pleading most piteously for water. The bowels may be constipated, or, less frequently, loose, with green or gray foul stools. The urine is scanty, and may contain albumin, casts and blood. In one case under my observation the child passed only a few ounces of dark-green, syrupy urine in twenty-four hours, which solidified on boiling.

Prostration, in severe cases, is always marked, and not infrequently a fatal termination seems imminent; but deaths from this cause are very rare. The duration of the attacks is from one or two to seven or eight days.

Diagnosis, when one is familiar with the condition, is usually not difficult. Acute digestive disorders may be excluded by the absence of a history of dietetic errors, and the persistence of the vomiting and other symptoms; acute appendicitis by the absence of pain, tenderness, and rigidity; disease of the brain or kidneys, or beginning meningitis, at first readily suspected, by the progress of the attack, and the early development of the characteristic urinary findings. That acidosis and vomiting are frequently observed at the onset of an acute infectious disease may sometimes mislead one, and seeing a child for the first time with an attack of the kind we are considering, I am in the habit of mentioning this to the parents, lest pneumonia or one of the exanthems

---

unexpectedly supervene. A history of similar previous attacks of course aids in determining the nature of the present one.

The etiology and pathology of this condition are still obscure. Because of the infrequency of death from this cause, we have almost no necropsy data. Necrotic changes in the gastric and intestinal mucosa,[2] degeneration of the glandular epithlelium, small hemorrhages and ulcerations, fatty infiltration of the liver,[3] and in one case, hypertrophic pyloric stenosis,[4] are about all that have been observed.

Marfan[5] in 1901 noted the presence of acetone with recurrent vomiting, and Edsall[6] in 1903 directed attention to the occurrence of large amounts of acetone and diacetic and oxybutyric acids in the urine. Since that time discussion of the subject has largely centered about the question of the rôle of these bodies in the production of the symptoms observed, whether they are of etiologic importance or merely morbid products of the underlying pathologic process.

Langmead[7] in 1906 doubted that they were the cause of the vomiting and other symptoms, stating that he never found them in the urine until well after the onset of the attack. Two years later he ascribed the production of the acid poisons to deficient oxidation of fats by the liver consequent on impairment of its functions by toxins derived from the gastro-intestinal tract, or bacterial activity in other parts of the body.[3]

Morse[8] considered the acid bodies a secondary manifestation, but believed that they were, in part at least, responsible for many of the peculiar symptoms.

Ratchford[9] considered the condition one of auto-intoxication, functional hepatic derangement causing an accumulation of purin bodies in the blood.

Ewing[10] regarded the trouble as a disturbance of fat metabolism, due to defective activity of the liver, associated with absorption of poisonous putrefactive products from the intestine.

Chronic appendicitis was assigned an important etiologic significance by Comby.[11]

Ely[12] asserted that the disorder was a neurosis, and Howland and Richards[13] ascribed it to an unstable state of the nervous system and regarded shock or excitement as the cause of a disturbance of metabolism leading to diminished oxidation, with the circulation of the unoxidized substance in the blood. Such substances being excreted into the stomach, the vomiting may be considered as an attempt of the body to rid itself of them. My own experience with these cases indicates the undoubted importance of the nervous element in their etiology. I see very many of them, for example, at such times as Christmas week, and following children's parties, in little patients in whom the question of dietetic errors as a factor may be entirely excluded.

Janeway and Mosenthal[14] thought that carbohydrate starvation might be a causative factor, as a deficiency of carbohydrates in the diet will produce an acetonuria. Sedgwick,[15] in 1910, called attention to the occurrence of creatin in the urine of a child subject to recurrent vomiting, and later,[16] reported further cases in which creatinuria was observed. Mellanby[17] reported similar findings in the case of a boy aged 6, in whose urine creatin was always present, increasing in amount before the onset, and reaching a high level with the climax of each attack, the condition of the patient as regards acidosis apparently being immaterial, as the acid bodies usually considered at fault were sometimes present in large amount without causing any apparent change in the child's well-being. The attacks were considered as due to intestinal toxemia, with possible infection of the portal area, the acidosis being merely secondary to derangement of the glycogenic function of the liver, which, causing imperfect catabolism of the fats, an accumulation of aceto-acetic and beta-oxybutyric acids in the body results, these substances being intermediate products in the breaking down of the fats, which normally should proceed to the formation of carbon dioxid and water. The presence of creatin is explained by the fact, as shown by Cathcart,[18] that a deficiency of carbohydrates, or inability to utilize such as are present in the body, will cause this substance to appear in the urine in large amounts. The hypothesis was advanced by him that carbohydrates are essential for protein metabolism, as they are for fat metabolism.

Finally, acidosis is common in children exhibiting catarrhal conditions of the nasopharynx, adenoids and diseased tonsils, and as before noted, acute coryza is a marked premonitory symptom of the attacks. Griffiths,[2] Comby,[11] Eustace Smith,[19] Sedgwick[20] and others have emphasized this relationship, and have noted marked improvement in these cases after removal of adenoids and tonsils, or other treatment of the nose and throat. I am convinced from my own observation that there is no other single factor so important, as a large proportion of the children I see with acidosis have bad throats and the recurrent attacks of acidosis and vomiting are relieved by proper treatment of the throat conditions.

Summing up and correlating all these various views as to the etiology of the condition, I may say that in children who suffer from periodic attacks of acid intoxication or recurrent vomiting, there is probably almost always some chronic focus of infection, adenoids, diseased tonsils, an inflamed bowel or appendix, or what not, the toxins from which, being constantly absorbed, act primarily on the liver. From time to time, by reason of the cumulative effect of the toxins, or to further disturbance of the already impaired equilibrium of metabolism by dietetic indiscretions, or by excitement, fatigue or other nervous element, there results a failure of the liver properly to perform its functions. The processes of carbohydrate metabolism are first disarranged, the frequency and severity of the attacks in childhood, perhaps, being due to the fact that the reserve supply of glycogen in the liver is not so great, proportionately, in children as in adults, and that therefore any interference with the glycogen-storing or glycolytic powers of the liver, there being no longer a proper supply of sugar available, induces an immediate disturbance of fat and protein metabolism, manifested by the appearance in the urine of the toxic bodies before described. How these operate to produce the prostration, vomiting, rapid wasting, vasomotor changes, nervous disturbances and other characteristic symptoms cannot yet be explained.

The consideration of treatment is largely omitted from the literature, or often discussed with a note of pessimism which is entirely unjustified to-day, as the little patients who suffer from this disorder offer excellent opportunity for successful therapy. Of fundamental importance, of course, is the determination and proper treatment of such foci of infection as have been referred to. Adenoids and bad tonsils will, I believe, be most commonly found, and their removal is usually followed by complete cessation of the acidosis attacks. Similar relief has frequently resulted from appendectomy in properly selected cases. Next in importance may be placed a properly balanced dietary, low in fats, with ample amounts of carbohydrate in the form of suitable breadstuffs, crackers, dry cereal preparations, rice, etc., with simple sweets and milk and lean meats in moderation, with plenty of green vegetables and fresh fruits. Citrus fruit juices are of especial advantage because of their content of potassium citrate which is converted in the body to potassium carbonate, and so tends to maintain the alkalinity of the tissues. Grape-juices, being rich in alkaline salts, are also valuable.

Constipation may be overcome by dietetic measures or by mild saline aperients if necessary, and the child's general hygiene should be carefully conserved by a quiet outdoor life with avoidance of too great fatigue and excitement. Drugging is not to be recommended except that in children with frequent recurrence of attacks, a periodic thorough emptying of the large bowel with a saline laxative or castor oil, with the administration of a dram or two of sodium bicarbonate one day per week may be beneficial. The routine daily use of an alkali is, of course, inadvisable because of its deleterious effect on gastric digestion.

Impending attacks, if recognized, may often be aborted by prompt catharsis and the free use of sodium bicarbonate as recommended by Edsall,[6] and favorably reported on by Pierson[21] and many others. Routine examinations of the urine will often give warning of the approach of an attack even before the onset of prodromal symptoms. In the treatment of an established attack, the bicarbonate is valuable not because of any neutralizing effect on the acid bodies, but because it stimulates their excretion, and probably exerts a protective influence on the body fats. It may be given by stomach, if vomiting does not prevent, or preferably by rectum, in doses of 60 grains in 3 or 4 ounces of water every three or four hours, or more or less continuously by the drip method; and in extreme cases, by intravenous injection. To meet the need for carbohydrate, sugar must be given in that form in which it is most available for utilization, namely, dextrose. It, too, may be administered by mouth, by rectum, in 4 per cent. solution with alkali, or by hypodermoclysis if the symptoms are urgent. So-called "corn-syrup," sometimes recommended for this purpose, is commercial glucose, derived from starch by the action of hydrochloric acid under pressure of steam, and as it contains only about 30 per cent. of dextrose and over 50 per cent. of dextrin, it should not be used if true glucose can be obtained.

Extreme drying out of the tissues may be counteracted by saline infusions, prostration by appropriate stimulants, and nervous symptoms by opium, chloral or bromids, or by ice-packs or moist packs. As the vomiting subsides, gruels may first be given with orangeade or other fruit-juice drinks, gradually increasing the diet to normal.

Convalescence is frequently surprisingly rapid, and the little patient, except for the wasting, will soon show no signs of what, a few days previously, appeared to be so serious an illness.

Berkeley National Bank Building.

ABSTRACT OF DISCUSSION

Dr. John Zahorsky, St. Louis: Dr. McCleave describes the color of the cheeks as being dusky. One of the most important symptoms of acid intoxication is a deep flushing of the cheeks, but I would not call it dusky. It is really a scarlet. The diagnosis is almost certain at a glance wh the child has this peculiar color and is breathing very rapidl I recall the case of a child who had these attacks and wh after circumcision, had no attacks for nearly a year. C course, the mother attributed the improvement to the ope ation. The operative shock does seem to modify certa phenomena. The removal of the appendix, for instance, r doubt has a beneficial influence on nervous diseases.

I believe that this disease is related to migraine. I reca a family in which the mother has severe migraine attack One child has asthma, another has eczema and another h cyclic vomiting. showing a nervous disturbance throughout tl whole family. I have noticed marked enlargement of the live in two severe cases. The liver should be palpated in a cases. It has been definitely established that enlargemen of the liver does occur in these severe cases. One patien was very sick. We thought the child would die. I marked out the liver on the abdomen daily and found it extending several inches below the margin of the ribs. On a subsequent visit I detected that it had receded half an inch. I then gave a favorable prognosis, although the other symptoms were still as severe as before. I would give enlargement of the liver as an additional symptom to be watched for in severe cases of this disease.

Dr. J. R. Snyder, Birmingham, Ala.: Dr. McCleave has not mentioned a certain type of case common in the South. It occurs in children younger than those indicated by the age limits he gave; most commonly in infants between 8 and 18 months of age. It is characterized by an acute onset, vomiting, increasing dyspnea and enlargement of the liver. In the article read by Dr. Thomas D. Parke in this Section several years ago, the symptom-complex of the disease was said to consist of a low-grade temperature, as a rule, intense thirst, vomiting, increasing dyspnea, constipation, dark green or tarry stools, enlargement of the liver, such urinary findings as occur in any acidosis, and so on. We see a large number of these cases in the South. We have come to regard them as among the most serious with which we have to deal. The mortality is over 80 per cent.

Dr. C. H. Johnson, Grand Rapids, Mich.: This is a comparatively new disease. About eight years ago I had a severe case. The boy had been ill ten days with recurrent vomiting and was nearly dead when I first saw him. These children have attacks of indigestion and vomiting, and we are apt to think of a gastro-intestinal trouble. We simply do not recognize the condition. My own son had recurrent vomiting for four or five years before I made a correct diagnosis. These attacks were never ameliorated in the least until I had thoroughly removed the stumps of tonsils that had been taken out several years before that. With complete removal of the tonsils he recovered. The case I referred to before was the worst I ever saw. The attack always began with stuffiness in the nose and a slight sore throat, and what I concluded was inflammation of very small adenoids. That boy did not make any improvement until the nose and pharyngeal space were put in good condition.

Dr. Thomas B. Cooley, Detroit: I am glad that Dr. Snyder spoke of the severe cases in babies. I think that they deserve to be distinguished from the type of acidosis which we find

---

21. Pierson: Arch. Pediat., 1913, xx, 505.

in so-called recurrent vomiting. I have seen a number of these cases in babies anywhere from 7 to 18 months or 2 years of age. The acidosis seems to be an accompaniment of an acute infection—often of the influenza type. Prostration is great from the start. The children do not always have a low temperature—I have seen it 103 F. and over—and they have great air hunger, severe prostration, not much vomiting, perhaps, and not so severe or so difficult to check as in cases of recurrent vomiting in which there is a strong nervous element.

Dr. I. A. Abt, Chicago: It seems to me that the altered constitutional state due to abnormal acid in the urine must be somewhat more carefully differentiated than has been the custom in the past. Acetone, diacetic acid, butyric acid, creatin and creatinin may all be recovered from the urine of children ill with various conditions. Acetone and diacetic acid occur in normal children. Undoubtedly they also occur in various forms of infection. The class of cases that I wish to refer to are those considered by Dr. Parke in this Section some years ago and referred to this morning by Dr. Snyder. I have seen a number of these cases. I am sure that the condition is not so infrequent as would be supposed from the scant reference in the literature. There is a group of babies, from 8 to 18 months of age, particularly at the weaning period, who fall ill with gastro-intestinal symptoms consisting of vomiting, slight diarrhea and rapid pulse, with a low temperature. The first striking symptom is the rapid breathing. Some pallor is noticed and, by and by, great prostration; soon constipation occurs, followed nearly always by more or less complete loss of intestinal tone, with symptoms which may simulate an obstruction. The baby passes neither gas nor stool. I am sure that this is a definite type of case. I have seen a number of them, some even during the time when breast-feeding was the exclusive diet and some during the transitional period from breast-feeding to that of artificial feeding. The urine contains acetone, diacetic acid and sometimes leucin and tyrosin with a trace of albumin. A brief reference to some case histories may throw light on the course and etiology of the disease.

A healthy baby was born to parents in perfect health and remained well until about the ninth month, when it was weaned. In a few days he developed the symptoms of gastro-intestinal disturbance mentioned previously and died in a few days. Some time later another baby was born. He also was healthy and strong and had never been sick up to the ninth or tenth month. He developed the same symptoms and died. The urine contained acetone, diacetic acid, oxybutyric acid, creatin and creatinin.

Another baby was born. The same symptoms developed. We examined the mother's milk and urine carefully. The breast-milk showed nothing, but the urine contained a small amount of sugar. One night the baby seemed about to die. We gave large doses of carbonate of soda, took away fat and gave skimmed milk, soy-bean flour, gelatin by mouth and glucose solution per rectum. We felt that starvation was possibly an important etiologic factor in producing these acid conditions. Eight per cent. glucose solution with normal salt solution we believed might be absorbed without being oxidized in the liver, and possibly counteract the intoxication. A 2 per cent. solution of sodium carbonate was given under the skin. The baby was better the next day and recovered in a few days. The carbonate of soda solution produced an immense slough, as large as the palms of two hands.

What caused this intoxication? We have concluded from experiment that it was not the breast-milk. The mother's urine cleared up in a few days and the sugar disappeared. We thought the fact that two other children had been similarly ill pointed, first, to a family type of disorder, and secondly, to something wrong in the metabolic functions of this baby; that some defect of the organism rendered it impossible for him to take care of some particular foodstuff. Was it a fat intoxication? It did not present the symptoms or reactions usually observed in fat intoxication of infants. Nor did the condition correspond to any known clinical type of sugar intoxication. Possibly this severe and unusual form of acid intoxication is due to some albumin, the nature of which we are unable to determine at present.

Dr. J. L. Morse, Boston: I have written and talked a good deal about acid intoxication. I thoroughly believe that there is such a condition in children, because I have had cases in which parents recognized the odor of acetone bodies in the breath and urine and in which they have been found present in large quantities before the onset of symptoms. I believe that it is the cause of some cases of recurrent vomiting. Someone said that the condition was not being recognized as often as it should be. My experience in the last year or two has been, not that it is not recognized, but that a great many other things are being called acid intoxication that have no relation to it, the reason being that someone has found a little acetone or diacetic acid in the urine. Anyone who has examined a large number of urines will be surprised to find how often these substances are found in the urine and how infrequently there are any symptoms from them. There are symptoms only when it is present in a considerable amount. One must be extremely careful in making diagnoses of said intoxication in children with vomiting and other symptoms simply because a small amount of these substances are present in the urine.

Dr. H. T. Price, Pittsburgh, Pa.: One fact that has impressed me is the tendency to consider this condition as being of nervous origin. So serious a condition is hardly of nervous origin, because we know from experience that if we permit a child to live properly we can prevent many of these attacks. Ordinarily we believe that acidosis is a serious condition, but that most patients recover. I am glad to learn that others have given a grave prognosis, because some patients have died under my care, and I have felt that I was at fault for not getting the results that we are led to believe should be obtained.

Dr. L. R DeBuys, New Orleans: I concur in the remarks of Dr. Abt, and I also feel that Dr. Morse has sounded a strong note. There is the other side to be considered, however. The tendency is for physicians to ridicule acid intoxication, and the sooner they appreciate the gravity of the condition the sooner more lives will be saved.

Dr. Zahorsky has made the same observation that I have regarding the peculiar flushing of the face. The flushing, at times resembling that of scarlet fever, is suggestive. As these patients improve, I have noticed the peculiar flushing disappear.

Another symptom of value in the diagnosis is that the temperature is usually low. The condition may start with some digestive disturbance and a somewhat high temperature. After the bowel has been cleaned out the temperature will decline. In fatal cases there is usually a gradual rise of temperature, signifying, I believe, that the means of eliminating poisons are locked up. These patients die, as a rule, with hyperpyrexia.

Dr. H. Lowenburg, Philadelphia: The point Dr. Morse brought out is important and calls to mind the history of two cases that came under my experience. One illustrates that not all cases of recurrent vomiting in children are due to acidosis. The child was 4 years of age. A diagnosis of acidosis had been made. On careful investigation of the urine no evidence of acidosis was discovered. Roentgenoscopy indicated the presence of a marked degree of pyloric spasm. An interesting feature was that the child recovered after half a dozen stomach washings and has had no recurrence for about five months.

The other was the case of an infant sent to me for recurrent vomiting with the diagnosis of pyloric obstruction. Here, too, a roentgenogram was made, and it showed kinking of the bowel in the region of the sigmoid. The infant was much constipated. The kink was the only thing that could be discovered. The pylorus was clear. The vomiting was probably reflex or toxic. This infant, too, recovered with use of high enemas of olive-oil.

Dr. Abt referred to a slough that followed the subcutaneous injection of bicarbonate of soda solution. I have given bicarbonate of soda by hypodermoclysis in about seven cases, and in each there was a slough.

Dr. Thomas C. McCleave, Berkeley, Cal.: With reference to the comment of Dr. Zahorsky and Dr. DeBuys in regard to the flushing of the face, I used the term dusky as best describing the appearance at the height of the attack. It is characteristic in the beginning that these children have a bluish, pallid ring under the eyes, sometimes a very intense white ring around the mouth and flushed cheeks. As the attack progresses and the intoxication becomes more intense, air hunger and cyanosis develop, diacetic and oxybutyric acids having a direct depressing effect on the respiratory and vasomotor centers.

I think that adenoids and diseased appendixes are of importance as sources of toxemia. We know that the liver is one of the most susceptible organs in the body to toxins of any nature. A disturbance of liver function results, and, unquestionably in my experience, removal of adenoids and bad tonsils or appendixes has worked a marvelous change sometimes in a child subject to attacks of this nature.

I purposely omitted from consideration the attacks in younger children referred to by other speakers as having been first described by Dr. Parke, as I am not at all sure that they belong in the category of the cases I had in mind.

Great care is necessary in the use of either sodium carbonate or bicarbonate under the skin or intravenously, as ordinary preparations of these drugs are contaminated; it is exceedingly important to have a chemically pure drug, or sloughs will occur. Dr. Fischer maintains that sodium carbonate is more valuable for the relief of acid conditions than the bicarbonate, for the reason that the sodium in the latter has already tied up to it as much acid as it will carry, and sodium carbonate has therefore a better combining value.

Dr. H. Lowenburg, Philadelphia: The last case of sloughing I had followed the use of Fischer's solution.

LEGAL ASPECT OF THE FEDERAL PROTECTION OF THE PUBLIC HEALTH *

W. C. RUCKER, M.S., M.D.
Assistant Surgeon-General, U. S. Public Health Service
WASHINGTON, D. C.

The public health policy of the United States has been one of gradual growth and change. In the first stage the general government assumed no authority whatsoever, other than to assist on occasions of emergency in the execution of the health laws of the state. In 1794, the Third Congress authorized the President to alter the place for holding the session of Congress if in his judgment there existed a prevalence of contagious sickness which would be hazardous to the lives or health of the members of Congress, and in 1796, he was authorized to direct the revenue officers and others to aid in the execution of quarantine and state health laws. This law was repealed in 1799. It was later reenacted. The act of Feb. 25, 1799, may be considered as the first public health law of the United States, and was the beginning of the public health work of the Treasury Department, the Secretary of the Treasury being empowered to make regulations governing the cooperation between the revenue officers and the government and the state health authorities. In 1798, the United States Marine-Hospital Service was created for the purpose of affording physical and surgical relief of the sick and injured men of the merchant marine and the navy. This act was amended by the acts of March 2, 1799, May 5, 1802, and Feb. 26, 1811. The authority of the Treasury Department to aid in the execution of the quarantine and health laws of any state was reaffirmed in 1832, and additional measures in aid of quarantine were enacted in 1866.

In the same year the first session of the Thirty-Ninth Congress, by joint resolution, authorized the Secretary of the Treasury to make and carry into effect such orders and regulations of quarantine as, in his opinion, may be deemed necessary and proper, in aid of state or municipal authorities to guard against the introduction of cholera into the ports of the United States. He was also authorized to direct revenue officers and officers commanding revenue cutters to aid in the execution of such quarantine and the health laws of the states.

It is highly probable that the passage of this law was brought about by the prevalence of cholera. This disease occurred in epidemic form in the United States during the years 1817, 1819, 1832, 1833, 1848, 1849, 1850, 1855 and 1866, but apparently fifty years were required for the people's representatives to realize that safety from disease meant its exclusion from abroad.

In the second session of the same Congress, by joint resolution approved Feb. 28, 1867, the Secretary of War and the Secretary of the Navy were again authorized to place at the disposal of the quarantine authorities of the states vessels and hulks for quarantine purposes.

The second session of the Forty-First Congress, by an act approved June 29, 1870, reorganized the Marine-Hospital Service, changing it into a compact and coordinate organization, having at its head a single officer charged by law with the supervision of all matters connected with the Marine-Hospital Service and the disbursement of funds provided for its maintenance.

The decade which followed was marked by some of the most wide-spread outbreaks of yellow fever which the United States has ever suffered. The officers of the Marine-Hospital Service, by reason of their familiarity with the disease and the fact that they were the only mobile sanitary force which the government possessed, were frequently thrown out on the firing line of yellow fever. At that time the entire corps did not exceed more than fifteen or twenty officers, yet they were sent into the worse infected localities to fight a disease whose mode of transmission was at that time unknown to the medical profession. The year of 1878 witnessed a frightful outburst of yellow fever which attacked the entire South, and for a time completely paralyzed its external commerce and its internal administration. It is estimated that during this outbreak over thirty thousand people were attacked, of which number at least fifteen thousand perished. This was the second great scourge of yellow fever in the lower Mississippi Valley, the first occurring in 1853 during the months of June, July and August, during which sixteen thousand persons, of whom eight thousand died, were attacked in New Orleans alone. The 1878 outburst, occurring just twenty-five years later, found a large non-immune population, and the disease swept up and down the Southern states like wildfire.

This impressed on Congress the fact that the sanitary policy which was then being pursued was not a wise one and that a change must be made. As a result, a law was enacted to prevent the introduction of contagious or infectious diseases into the United States. This act was approved April 29, 1878, and provided for consular bills of health and for reports by the consular officers to the Supervising Surgeon-General of the sanitary condition of the ports at which they were stationed. The Surgeon-

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints.

General was charged, under the direction of the Secretary of the Treasury with the execution of the provisions of that law and the promulgation of rules and regulations necessary for the conduct of quarantine. It was expressly provided in this law that such rules and regulations should not conflict with or impair any sanitary or quarantine laws or regulations of any state or municipality. The enforcement of the national quarantine rules and regulations was made a duty of the medical officers of the Marine-Hospital Service, and the policy was adopted that the protection of all the states against disease from foreign countries, or from one another, was the function of the federal government.

The issuance of bulletins of health had been authorized by previous act of Congress, but in the act approved March 3, 1879, an appropriation was made for the publication of these bulletins. This may be said to be the beginning of the policy of the government's issuing from time to time information of a public-health character.

This was in reality the second stage in our sanitary policy, one from which we departed in the following year and one to which we gladly returned a short time later.

The basic idea of this policy is the protection of the individual person, locality, or state by the state and municipal authorities, and the protection of the mass by the general government. It presupposes on the part of the states a pride and an unwillingness to surrender to the general government any function which they can satisfactorily discharge. On the other hand, it expects of the general government that it will protect the states against one another, that it will bear the burden when more than one state is involved, and that it will not allow the states to take harm through commerce. It expects the states to endeavor to solve their own problems, but it demands that the general government shall undertake the study of matters which concern all of the states, or which demand the services of experts for the conduct of expensive experiments.

This is a wise and far-reaching policy and one which in the end will bring about the greatest and most lasting good. Unfortunately, this was not realized at the time it was first adopted and there was created by the act approved March 3, 1879, a national Board of Health to meet the desires of those persons who were not satisfied with this form of sanitary policy. By the provisions of this act there was created a national board of eleven members, seven of whom were to be appointed by the President, the remaining four to be one medical officer each from the Army, the Navy, the Marine-Hospital Service, and one law officer from the Department of Justice. The powers and duties of this board were wide and contemplated the creation of an even larger and more powerful health organization. This power was further increased by the act of June 2, 1879, a measure which in its all-embracing character recalls bills which have been before Congress for the past two or three years.

On June 14 of the same year, by joint resolution of Congress, the Secretary of the Navy was authorized to place vessels or hulks at the disposal of the national Board of Health for quarantine purposes.

As if this were not enough, the first session of the Forty-Sixth Congress, in an act approved July 1, 1879, granted still further powers and an appropriation of $500,000 for the carrying out of this experimental sanitary legislation; office rooms were provided for the national Board of Health, and funds were provided for the publication of its reports and papers. This act also authorized the employment of stenographers and a chief clerk, and granted authority for the board to erect temporary quarantine buildings and to acquire real estate, or to rent houses for that purpose.

By an act approved April 18, 1879, the Secretary of the Treasury was authorized to contract for the purchase or construction of a refrigerator ship for the use of the board in the disinfection of vessels or cargoes, or for other purposes, and for this $200,000 was appropriated.

By joint resolution of April 18, 1879, the first session of the Forty-Sixth Congress ratified the organization of the national Board of Health. This action was necessary because the board had failed to take the oath of office. The joint resolution provided for the organization of the board without the taking of the oath of allegiance.

The following year, by the act of June 16, 1880, $100,000 was appropriated for the use of the national Board of Health, and by the act approved March 3, 1881, an appropriation of $225,000 was made for the use of that board. By the act approved August 7, 1882, $50,000 was appropriated for the use of the national Board of Health, but the law provided that the duties and investigations of that board should thereafter be confined to the diseases of cholera, small-pox, and yellow fever. By the act approved March 3, 1885, $10,000 was appropriated for the compensation and personal expenses of the national Board of Health. By an act approved March 3, 1885, provision was made for the salaries of the secretary and messenger of the board and for the rental of its offices. By an act approved March 3, 1885, $5,000 was provided for salaries and expenses of the national Board of Health for the fiscal year ending June 30, 1886. No further appropriations for the use of the national Board of Health appear in the acts of Congress, and by acts approved March 5, 1888, Aug. 1, 1888, and Oct. 1, 1888, the quarantine function was returned to the Treasury Department. There is little doubt that the persons who fathered this movement were genuinely sincere in their efforts and that they were guided by high ideals. The formation of the national Board of Health, however, was an attempt at the formation of a sanitary empire within a republic, and when the money which had been appropriated for its maintenance gave out the entire fabric fell to the ground of its own weight. On Aug. 1, 1888, there was approved an act which transferred to the Marine-Hospital Service the function and administration of quarantine, but it was not until the approval of the act of Feb. 15, 1893, that the national Board of Health was officially stricken from the roster of the United States. That organization had during the first part of its brief life the unqualified backing of Congress. Numerous acts were passed granting it authority, functions and funds, but it never accomplished what its supporters hoped for it, because the basic principle on which it rested was contrary to the spirit of the general government. This should be of value in the future, because it should never be forgotten that any institution in this country which is to endure and functionate to the good of our country must be in harmony with the spirit of American institutions. The national public health organization of the future must follow the policy of supplementing the states where they are weak, of assisting them in situations which are beyond their power and resources to control, to prevent the spread of disease in interstate and foreign commerce, and to maintain the sanitary integrity of the units entering into the formation of the general government. The national Board of Health functionated from 1879 to 1883, when it was allowed to die of inanition.

By the provisions of the act approved Aug. 7, 1882, a fund was created which has since come to bear a very important relation to our sanitary defenses. It is called the fund "for the prevention of the introduction and spread of contagious diseases." As originally enacted, the President of the United States was authorized in case of actual or threatened epidemic to use a sum not exceeding $100,000 for aid of state and local boards of health or otherwise at his discretion in preventing and suppressing the spread of the epidemic. This law was reenacted by the act of March 3, 1883; and by the act approved July 7, 1884, it was provided that the President might also expend the money in maintaining quarantine at points of danger. The act approved March 3, 1885, reappropriated the unexpended balance and added $300,000 to this fund. The expenditure of this sum, however, was authorized only in the case of threatened or actual epidemic of cholera or yellow fever. In the act approved March 3, 1891, the disease small-pox was added to this list, and in the act approved Aug. 18, 1894, the Chinese plague, or black death, was also added. In the sundry civil appropriation act approved June 28, 1902, typhus fever was included in the list, since which time these five diseases—cholera, typhus fever, yellow fever, small-pox, bubonic plague, Chinese plague, or black death—have been considered as diseases the cost of the measures against which may be chargeable to this fund. The President is authorized to spend this money in aid of state and local boards, or otherwise at his discretion, in the prevention and suppression of these diseases, and also in such emergencies in the execution of any quarantine laws which may be in force. The fund has been added to from time to time by the various congresses.

In the meantime, the United States Marine-Hospital Service had been growing, the number of its personnel was increased, and by the act approved Jan. 4, 1889, the method of appointment into the service and the salaries and commissions of its officers were regulated.

The first session of the Fifty-First Congress, in an act approved March 27, 1890, brought about a new phase in our public health policy. Up to this time, aside from the work of eradicating epidemic outbreaks within the states, the national health authorities had largely concerned themselves with the questions of maritime quarantine, leaving out of consideration the matter of the prevention of the introduction of contagious diseases from one state or territory into another, or from any state or territory into the District of Columbia, or from the District of Columbia into any state or territory.

The act referred to had to do with cholera, yellow fever, small-pox and plague. It provided that when it was made to appear to the satisfaction of the President that these diseases existed in a state or territory or the District of Columbia, and there was danger of their spread into other states, territories or the District of Columbia, he was authorized to cause the Secretary of the Treasury to promulgate such rules and regulations as would control and prevent such spread. He was further empowered to employ such assistants as might be necessary for this purpose. The preparation of these regulations was left to the Supervising Surgeon-General of the Marine-Hospital Service, under the direction of the Secretary of the Treasury. Penalties were attached to the infraction of such rules and regulations and the law specifically included in its penalty clause common carriers and their servants. This was the beginning of the policy for the control of disease in interstate traffic, and as will be shown has grown until it includes other diseases than the major pestilences, and it is believed that the future will see its extension to the point where common carriers engaged in interstate traffic will be regulated to the end that they will not be permitted to bring disease either to passengers or to persons living along the right of way. Such an extension was brought about in 1893 by an act which will be referred to later.

In the following year the Fifty-First Congress, in its second session, by the act approved March 3, 1891, took cognizance of the danger of the importation of disease into the United States by arriving alien immigrants, and there was added to the functions of the Marine-Hospital Service, which already included the medical and surgical relief to the sailors of the merchant marine and the management of maritime and interstate quarantine, the function of the medical examination of arriving aliens.

The following year, 1892, is important in sanitary history because of the large outbreak of cholera which took place in Hamburg, Germany. Our nation was at that time in great danger of the importation of that dread disease into the United States. This was fully realized by Congress, which, by the act approved Feb. 15, 1893, entitled "An Act Granting Additional Quarantine Powers and Imposing Additional Duties on the Marine-Hospital Service," created further barriers against the importation of diseased persons and things from abroad. This law is of great importance, and includes not only the measures to be taken at ports of departure and arrival, but also in Section 3 provides for the enforcement of quarantines between the states. Its careful study is to be commended to any one interested in the furtherance of the national protection of the public health. It may be noted that the law provides that the Surgeon-General shall cooperate with and aid state and municipal boards of health in the execution and enforcement of the rules and regulations of such boards and in the execution and enforcement of the rules and regulations made by the Secretary of the Treasury to prevent the introduction of contagious and infectious diseases into the United States from foreign countries and into one state or territory or the District of Columbia from another state or territory or the District of Columbia. It is required that these rules and regulations shall operate uniformly and without discrimination against any port or place. The law provides that they may be enforced by the state or local health authorities when they will undertake to do so, but in the event of refusal or failure of such boards to enforce the regulations of the Secretary of the Treasury for the prevention of the spread of disease in interstate traffic, the President shall execute and enforce the same and adopt such measures as in his judgment shall be necessary to prevent the introduction or spread of such diseases, and that he may employ or appoint persons for this purpose. Further, the Secretary may make additional regulations for the prevention of the spread of disease by common carriers. It is under this section that the interstate quarantine regulations have been issued, and recently they have been amended and expanded with the idea of protecting the health of passengers in interstate traffic. It is hoped that eventually they can be amended so as to include the further regulation of the transportation of the dead, as well as the regulation of the transportation of diseased persons and things. It is hoped that they can be extended to the point where many of the commoner, but none the less serious diseases from a public health point of view, can be included in the proscribed list. The recent amendments apply particularly to the water and ice supplied for use by passengers in interstate traffic on common carriers and abolish all common roller-towels and common drinking-cups and provide for the regulation of the transportation of lepers. These recent amendments have been well received by the common carriers, and already many of the railroads and steamboats are expending considerable sums in providing safe water and ice for their passengers. When the water and ice regulation shall have been applied in its entirety it will mean that every source of water-supply used by common carriers in this country shall be subject to careful bacteriologic and chemical examination at least once in every six months and certificate of such examination filed with the United States Public Health Service. This is bound to have a most beneficial effect and will raise the standard of water generally used in this country.

Quite recently the Secretary of the Treasury appointed a commission of fifteen of the leading water experts of this country to set a standard of purity for water to be supplied for passengers on common carriers in interstate traffic. When this commission shall have rendered its report and the standard set by them shall have been adopted, it will be incorporated in the interstate quarantine regulations and we shall have the first federal standard for purity of water.

The law of Feb. 15, 1893, which we are considering, gives the Surgeon-General additional authority to collect morbidity and mortality statistics in the United States and foreign countries and for the publication of the data so collected in *Public Health Reports*. It also provides for the voluntary cession by a state of its quarantine establishments to the federal government.

From time to time Congress has made appropriations for the study of special diseases. Thus, in the law approved March 2, 1895, appropriation was made for experimental investigation of the treatment and prevention of small-pox in the laboratory of the Marine-Hospital Service, and in the act approved March 2, 1899, provision and appropriation was made for the appointment of a commission of medical officers of the Marine-Hospital Service to investigate the origin and prevalence of leprosy in the United States.

In the act approved March 12, 1900, the quarantine function of the United States was extended to Porto Rico and placed under the jurisdiction of the Marine-Hospital Service, and on April 3 of the same year the Fifty-Sixth Congress in its first session passed a similar act providing for quarantine for the Territory of Hawaii.

In the act approved March 3, 1901, the second session of the same Congress amended the act of Feb. 15, 1893, providing penalties for trespassing on federal quarantines and for entering ports of the United States without a proper bill of health.

The Fifty-Seventh Congress in its first session enacted a law, which was approved on July 1, 1902, which was designed to increase the efficiency and change the name of the United States Marine-Hospital Service. This provided for a change of name to the Public Health and Marine-Hospital Service of the United States, fixed the salaries of the officers, authorized the President to utilize the service in times of threatened or actual war in such manner as would promote the public interest, provided for an advisory board of the Hygienic Laboratory and established the division of chemistry, zoology and pharmacology in the before-mentiond laboratory. It further provided for the annual conferences to be called by the Surgeon-General between the federal Public Health Service and the state and territorial health services. The Surgeon-General was further authorized to collect morbidity, mortality and vital statistics.

Not content with this most excellent law, Congress on the same day passed an act to regulate the sale of viruses, serums, toxins and analogous products in the District of Columbia and to regulate interstate traffic in such articles. The application of this act has brought about the licensing of the manufacturers of the various biologic products which are used in the treatment of disease, the establishment of standards of potency for diphtheria and tetanus antitoxin and has acted as a public health measure of far-reaching importance.

In its third session, the Fifty-Eighth Congress by joint resolution provided for the publication of the annual reports and bulletins of the Hygienic Laboratory and of the Yellow Fever Institute of the Public Health and Marine-Hospital Service. This act, which was approved Feb. 24, 1905, has been the means of disseminating much knowledge of a public health nature. The same Congress, March 3, 1905, provided for the investigation of leprosy, with special regard to the care and treatment of leprosy in Hawaii. This has brought about the establishment of a leprosy investigation station, which has added greatly to our knowledge of this disease.

In 1905 an outbreak of yellow fever occurred in several of the Southern states, notably in Louisiana, where, at New Orleans, occurred the first application of the then newly acquired knowledge of the transmission of yellow fever by the mosquito. It is true that in the epidemic at Laredo, Tex., in the preceding year, the mosquito theory had been tried on a small scale, but the work at New Orleans was its first employment in what may be called grand tactics. The success which crowned the efforts of the Public Health and Marine-Hospital Service in the New Orleans epidemic inspired the Fifty-Ninth Congress, in its first session, to pass an act to further protect the public health and to make more effective the national quarantine. This act was approved June 19, 1906, and resulted in the cession of the United States of practically all of the southern quarantines.

During all this time the various branches of the Public Health and Marine-Hospital Service had been busy in their respective fields, and in the sundry civil act approved March 4, 1911, Congress added to the utility of the marine hospitals by making of them true public health hospitals. The act referred to contained the following phrase: "Provided, That there may be admitted into the said hospitals , for study, persons with infectious or other diseases affecting the public health, and not to exceed ten cases in any one hospital at one time." Thus, the marine hospitals have now become centers for the clinical study and investigation of diseases which affect the public health.

Finally, on Aug. 13, 1912, the Sixty-Second Congress passed the act referred to in the opening paragraph of this paper. This was approved on the following day. It changed the name of the service to the Public Health Service and it provided that in addition to the duties required by law the Public Health Service may study and investigate the diseases of man and conditions influencing the propagation and spread thereof, including sanitation and sewage, and the pollution, either directly or indirectly, of the navigable streams and lakes of the United States; and it may from time to time issue information in the form of publications for the use of the public.

This brief review of the legal aspect of the federal protection of the public health does not pretend to be complete. The many acts which Congress has made bearing on individual problems, such as the support of vaccination, the investigation of yellow fever, and certa quasi-public health measures have not been mentioned, as it is thought that they would attract interest from the main thread of the discourse. I feel that whoever would undertake the legal reformation of the public health might find the desire to have at hand in compact form a few items, important references and the like, which should be carefully considered before undertaking the drafting of any such legislation. It is hoped that a study of these laws will make evident the fact that Congress has made new laws as rapidly as it saw the necessity for so doing, and it is evident from its action in the past that it will act with equal intelligence in the future. The misstatement has frequently been made that the federal government has enacted more legislation for the protection of domestic animals than for the protection of man. It is believed that a careful study of the comprehensive laws already written on the statute-books will incontrovertibly contradict this statement. Congress has gone about building up the public health defenses of the nation on a strong, broad basis, and any legislation which is to be enacted in the future must take full cognizance of this fact. The foundation is well laid; it remains for the people of this country to determine what sort of superstructure shall be erected thereon. If this is done carefully and with judgment, and with the ever-present idea of utilizing the vast body of laws already existent, instead of constructing a de novo edifice, we shall have an efficient and time-enduring structure. The mistakes of the past should guide us in the future, and whatever we may do, let us see to it that what we build is of practical usefulness and in conformity with the plan of our government and the spirit of our American institutions.

ABSTRACT OF DISCUSSION

Dr. Pauline M. Townsend-Hanson, Marshalltown, Iowa: I have no criticism to make of anything the government has done in the past. I want to make a suggestion or two with reference to the future. I notice that research work in regard to the conditions of man—as relating to health—is in the province of this department. Uncertainty of employment has an absolutely direct connection with health. The man out of work, or the man whose employment is inadequate during the year—or whose return for his labor is inadequate—cannot provide healthy conditions for his family. It lies within the scope of this department to delve into the question of uncertainty of employment and income to families.

Dr. James A. Hayne, Columbia, S. C.: I am sorry that the two great political parties in the United States seem to have overlooked the wonderful work that has been done by the United States Public Health Service and failed to embody in their platform a department of public health. We believe that the Democratic administration will carry out its platform and we believe that there will be a department of public health established in Washington, with a cabinet officer at its head. How this is going to be done—and whether the U. S. Public Health Service is to be incorporated in this department—we do not know; but we believe that such a health department must come if effective prevention of disease is to be accomplished.

Dr. W. C. Rucker, Washington, D. C.: I would remind the doctor that there is already a bureau of public health established by act of Congress on August 13, 1912. You mean a department, do you not?

Dr. James A. Hayne, Columbia, S. C.: Yes, a department, with a cabinet officer.

Dr. W. C. Rucker, Washington, D. C.: The question of the expansion of the breadth of public health activity has been brought up by one of the speakers. The matter of wages and of non-employment has already been investigated to quite an extent by the federal government. It has been taken up as an economic measure. It is certainly true that the question of employment as well as of housing, and questions of every thing which has to do with environment, have to do with the public health. The data are available for public health workers.

There is one thing to be thought about in connection with the expansion of any function or any work; it is better not to expand too much; you may find your butter spread out pretty thin, or you may be able to find none of it on your bread when you come to eat it. It is a wise thing, too, in thinking about these things, to go over the laws and to see that Congress has built with a breadth which none of us could have imagined; and it has placed its large foundation on the only proper basis and clear down to bedrock—the Constitution of the United States.

THE NEED OF WHOLE-TIME HEALTH OFFICERS [*]

HAROLD B. WOOD, M.D., D.P.H.
ROCHESTER, MINN.

Health is the indispensable asset of life and cannot be acquired without effort. Health to the individual is inherited; but to the nation, acquired. People have so far deviated from those instinctive habits which in their forebears maintained health that they require a professional class to teach them the principles of avoiding disease and of maintaining bodily vigor, health and efficiency. The recent elevation of public health work from a recreation to that of a profession as an entity, or from a social to a sociologic atmosphere, has placed the theory of public health on a new basis.

When the origin and transmission of diseases was little understood, the work of the health officer was uncertain and difficult, and received a corresponding response from the doubting and credulous public. Most health officers are able to produce but little in the way of results. This is due in part to the lack of public support. Many communities still either disregard the value of the conservation of public health, or else have not been shown wherein they need assistance. People are usually satisfied with existing conditions until some one demonstrates what improvements are needed. With the attitude of self-satisfaction, legislative bodies refuse to give the necessary support. The wide-spread opposition is partially due to the inactivity of those practicing physicians who are wont to be termed health officers. Even though receiving only a meager salary, each health officer should give more service for the public good than he receives compensation for, or the position might be abolished.

If a community entrusts its health, its questions of sanitation, the life of its schoolchildren, its danger from transmissible disease, its industrial conditions and its uncertain food-supplies to a busy medical practitioner, the public duties of that health officer can scarcely receive the attention they need. No time can be given for investigating, for following up contact cases, for searching for carriers or for carrying on any propaganda of reform, improvement or public instruction.

Many practitioners seek appointments as health officers with the object of establishing names, of making acquaintances or of receiving small checks without the expectation of rendering services. There are many laymen who debar from their homes the health officer who sees contagious diseases; there are those who condemn the sincere health officer's methods or opinions, or who declare that the officer is indirectly forcing people to consult him. There are many others, both in and out of the profession, who have altruistic motives and understand the import of the work. The service is discouraging to the practitioner in that it frequently causes a restraint of practice or an abuse of privilege by the public. Local professional jealousies also result.

---

[*] Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

The fear of apparently discriminating against another man's patients or of invading his territory or of losing one's own practice has put the damper on many a willing health officer. The opinion that he is booming his trade or emitting spite against others is the usual reason for the public's disregard for his attempts. It is usually the health officer who has more enthusiasm than practice, with no desire for professional friendship, and who has a free hand, not hampered by calls, friends or politics, who becomes the successful and useful health officer. The neglect or failure to perform public health service while a man is attending private practice results in public damage. This can best be obviated by the employment by a community of a health officer who devotes his entire time to the work. This is a method of procedure that is eminently philosophic.

The modern whole-time health officer is not simply a registrar of statistics, a placarder of houses or a public prosecutor. He is a compiler of statistics, obtaining those records which have not been reported by physicians and classifying all as a means for the foundation of methods for the eradication of disease. He is a public instructor, teaching how health may be maintained and explaining that rules and placards are intended only for the careless and lawless. He is a true sanitarian, who supplies information on various branches of science and industry, but all for the same purpose—the protection of the public. His office should be a bureau of information, to collect and to disperse knowledge. He should not alone formulate, but also execute, plans for saving human life. The improvement of industrial, social, scholastic and vital conditions is his work.

The health officer must of necessity be a critic. His duty is that of pointing out to others the obnoxious or the dangerous. The man who criticizes without suggesting is not the modern man. His work is not merely to inspect, but also to improve conditions in the shop and industries. To give cold condemnation without detailed directions of methods for improvement produces little result except that of antagonism. The average man resents a criticism unless suggestions for improvements are offered. These suggestions should come well within the intellectual or financial ability of the owner to construct and to maintain. A series of suggestions should begin with those simple details requiring the least work or expenditure. It is important to explain the reasons for the changes advised. The health officer who in his suggestion to a dairyman begins with a consideration of tuberculin testing or installation of a flue system will meet with immediate opposition toward all improvements. When the most simple and least costly improvements are suggested first, dairymen accept suggestions and instal the improvements willingly. A list of "Twenty Dairy Suggestions" has been circulated, beginning with "Have the herd examined at least twice a year by a skilled veterinarian." More cooperation would be obtained if the first line began with "Shovel out the manure." Rural school boards can become more interested in public health work if the first suggestion given them concerned the individual tin cup, rather than the direction for admitting light or the most acceptable desks. The instruction and arguments must come within the comprehension of the listener.

The qualifications of a health officer depend largely on local conditions and on the particular kind of work to be done. As the educational facilities for training these men become developed and become appreciated and accepted, distinct lines of public health work may be classified. As the science of curative medicine is composed of various specialties, that of preventive sanitation will be composed of even more widely divergent groups. In the larger fields the work is too voluminous for a single man. It may require only a statistician, an epidemiologist, a diagnostician or an engineer, or one with a laboratory, educational or executive training. So must the health officer be selected, according to his ability and the public needs. A man should be known not alone by the degrees he holds but also by his ability to produce particular results. All esthetic or sanitary work which has but remote connection with the public health is of minor importance when there are lives which can be saved and diseases which can be prevented.

The elimination of disease is the chief duty of a health officer. Since in smaller communities this entails on him an ability to diagnosticate infections, the health officer should be a man of medical training. In Minnesota every township is required by law to have a medical health officer. In larger cities the character of the duties may require a sanitary engineer or, at least, a health officer who is not necessarily a medical graduate. If a city's greatest health problem is the control of disease, the health officer should be a specially trained physician. When there is little danger from disease, and the city employs a health officer to direct its rebuilding along sanitary lines, to keep it clean and to instal water, sewerage and scavenger systems, a sanitary engineer would be the more efficient man. Farmers, plumbers, ministers and carpenters scarcely have the necessary training to qualify them especially for the work of the medical health officer, yet to them is frequently entrusted the local public health.

Whether or not the supervision of garbage collection, street cleaning, sewage disposal, dust eradication, drainage and plumbing should be included in the duties of a health officer is apparently of local concern. In certain places these should all be placed in the hands of another, or entrusted to the city engineer or highway department, but in some smaller cities there seems to be none other than the health officer to manage these enterprises.

If state boards of health have a right to appoint local registrars for collecting statistics, requiring the counties to pay given fees for the work, it seems reasonable to believe that the same centralized authorities have a right to appoint whole-time health officers, to fix their duties, to limit their jurisdiction and to require the local counties to pay given or fixed fees or salaries. The making of appointments by the state board of health would have a tendency to remove from consideration politics, favors, personalities and social obligations, creating more of a civil service régime. The collection of vital statistics is necessary, but the control of those live, diseased and dangerous people, whom the morbidity statistics merely record, is a greater necessity. If a state board of health has the right to appoint local registrars of statistics who draw their pay from the local counties, it has a much greater right to demand that the counties appoint health officers who are efficient; if the counties fail in this, the state board of health should have the legal right to appoint and control local health officers, fixing their salaries and requiring that the compensation for service and expense be borne by the local county or community. As the health of a community affects the state and as the presence of local disease endangers neighboring communities, the state board of health should have the authority to determine the rate of compensation for local health officers when the local community fixes the salary at such a low figure that no effective work can be accomplished.

In New York,[1] the state commissioner of health may, by law, exercise the powers of a health officer, where health officers have not been appointed, the expenses incurred by him being charged to and paid by the municipality.

To determine in what localities the whole-time health officer is first needed is apparently a power of the state board of health. With the statistics of the local morbidity, with his knowledge of the environmental, racial, industrial, hydrographic and prevailing social influences, the state health executive should be able to determine what available man is best qualified. The jurisdiction of the municipal health officer should extend beyond the confines of the city, exerting an influence over that territory which affects the health of the city. This jurisdiction is exercised in parts of Massachusetts.

The states should be divided into health districts, each district to be presided over by a whole-time health officer. The districting of the jurisdiction of health officers had probably better be considered locally. The limits of a township or a county may give satisfactory results on one hand, but not on another. In a town near the border of a county it would be absurd for the health officer to have jurisdiction in the one county alone. If a community be equally dependent on two counties for those conditions which influence its health, the jurisdiction of the health officer needs wider scope. When adjoining counties combine to employ a whole-time health officer, the various counties entering into combination should have their union sanctioned by the state board of health, which is able to judge of the advisability of giving the health officer the proposed field of jurisdiction and is able justly to divide his time between the combining communities.

The union of the various counties could well be determined by the influence of the included cities or the direction of the railways. The location of the watersheds or drainage areas, the locations of affecting industries or food sources, the location of obstructing rivers or mountain ranges and the lines of commerce or school attendance are all factors which may be used in determining the size and shape of the district to be covered by the health officer. The ease or rapidity of railway travel for the health officer should be considered. It may be necessary to gerrymander rather than to select symmetrical areas as health districts. The topographic locations of those communities best or least able or willing to finance health projects is no small consideration. Neighboring towns can cooperate to employ one health officer who can serve both communities with the adjacent territory.

The size of territory or the population which can adequately be covered by a whole-time rural man would vary widely. It would depend partly on the man, largely on the particular line or lines of health work he was pursuing, and, to no inconsiderable degree, on the kind of transportation at his disposal. These factors would have corresponding weight whether the officer worked alone or with a corps of assistants.

In the recent state legislatures the subject of whole-time health officers was considered. In Minnesota a bill was introduced permitting communities or counties to employ such officers and providing an appropriation permitting the state board of health to assist in establishing the work. This bill died somewhere in the house committee.

In New York a bill to establish supervisory county health officers was passed. The plan provides for the retention of the present town and village health officers, but subordinates these to new officials who are trained public health experts with jurisdiction over larger districts. The state shall be divided into twenty or more districts. The sanitary supervisors are required to be physicians. The law does not specify the salary to be paid these supervisors, but it has been stated that $3,000 was the salary recommended. The law specifies that the minimum salary for the health officers of towns and villages shall be $800, and for towns with a population of less than eight thousand the minimum salary shall be equivalent to ten cents per inhabitant of the community served.

In Massachusetts there are a few whole-time health officials having jurisdiction over rural territory. Their salary is small, varying from $900 to $1,500.

In Michigan a bill drafted by Dr. Victor C. Vaughan was introduced providing for the division of the state into health districts, composed of one county each, except that each city of more than eighteen thousand should form a separate district. Any two counties having a population of less than twenty thousand might organize into a joint health district. Each district was to have a health commissioner, appointed for four years, whose salary would be from $1,500 to $3,000, according to population. This bill failed of passage.

The Pennsylvania county health officers are not whole-time men. They are appointed by the commissioner of health and are compensated by the state at the rate of $1.25 per hour, with expenses.

The value of a health survey for determining the needs of many communities is great, but not too much time or money should be expended on the survey. In a survey numerous conditions which need attention may be brought to light for the first time. The survey can be undertaken by an efficient, unbiased health officer and should cover all the influences over health arising from social, economic, educational and industrial conditions, from child welfare and the origin of disease to factory conditions and food-supplies. The information properly weighted will clearly indicate, as do weighted morbidity and mortality rates, the need of following some particular lines or locality in public health work.

In many localities the physicians probably do not see one half the cases of some infectious diseases. In an outbreak of 166 cases of measles in Rochester, only fifty-two cases were seen and reported by physicians, 114 being located by other methods. Of these 114 cases, however, fifty-seven were secondary cases occurring in homes already attacked, fifty-seven new cases being found in unreported households. The value of collecting complete morbidity reports as an indication of the health and need of a community is evident. Since the registrar usually receives these reports only from physicians, the records are far from accurate, because for the light cases no physicians are employed and the secondary cases in a household are not likely to be reported even though a doctor be in attendance. The light infections being the more dangerous to a community, it is important for their whereabouts to be known that thoughtless and indiscriminate exposures be checked. By the discovery and control of these mild cases the prevention of serious outbreaks is accomplished.

---

[1] State of New York, Tr. 1909, chap. 49, amended 1913, as chap. 559, xcii.

The hunting up of the unreported cases will, almost alone, be sufficient excuse and enough financial gain to recompense a community for adopting whole-time officers. If, by this means, sixty adults a year are prevented from contracting a disease which indisposes them for three weeks, the money saved will supply a health officer. Virtually, two cases of sickness, each of a week's duration, prevented each week will enable a community to employ the services of a whole-time health officer.

A large proportion of contagious diseases are contact cases occurring within the original household. Physicians have a tendency not to report these cases, probably considering the house, not the case, the numeral of morbidity statistics. The importance of knowing the secondary cases is for determining the efficiency of the isolation practiced, the length of incubation and infectivity, the necessity of fumigation and the time for release from quarantine. As shown by experience, the records of these secondary cases can seldom be obtained unless there is a systematic method of follow-up of the original cases with their contacts, which could be accomplished by a man who has the necessary time to devote to the work. When cases of transmissible disease occur, all exposed contacts should be regarded as suspects, being followed up before they in turn have the opportunity to transmit infection. The address is obtained of all susceptible children who are exposed. After the minimum incubation period has nearly elapsed, these contacts are visited, excluded from school and isolated if possible, until the maximum incubation period has passed. This plan may encounter some public opposition until its necessity is clearly explained. After the minimum incubation period has passed, it is advisable to placard the homes of those who are exposed and are susceptible to measles, scarlatina, whooping-cough and small-pox. It seems advisable to include whooping-cough with measles in the list of reportable diseases, and for smaller towns rubella and mumps, making every reportable disease a placardable disease. The results in Rochester show that isolation and placarding have been the greatest factors in decreasing disease. Many houses are not placarded early enough because these contacts cannot be discovered. The rules following placarding have been generally observed, and no outside secondary cases have developed from the placarded homes.

The municipal health officer should be apprised of cases of transmissible disease which occur in the immediate locality which supplies food or water to the city. The cooperation between rural and municipal health officers may frequently prevent great damage being done to the city. Should a country physician or rural health officer learn of the probable contamination of a municipal water-supply by typhoid discharges, the city should immediately be notified of the facts. When the county practitioner is called in a case of typhoid, he should immediately notify the local health authority of the conditions, giving all connections, present and remote, that the patient has had with any supply which later becomes a public food or drink.

The control of contagious diseases in schools depends on the exclusion of the children before they begin to show symptoms. This may be accomplished by following up all susceptible children who have been in contact with infective cases, and excluding them from school after the minimum period of incubation for the particular disease has passed. The homes should then be placarded and the children watched until the maximum incubation period has passed. Whether they develop the disease or not, the children should be returned to school at the earliest day after the stage of infectivity has passed. Most people are not able to give the names of all others with whom their children have come in contact during the previous few days, and those who are thereby overlooked are sufficient to keep the exanthems endemic in any city.

When a case of communicable disease appears in the country, it is the duty of that community to prevent transmission of the disease. Some one by a personal visit should obtain a list of the addresses of all susceptible persons who have recently been exposed. Each locality into which they have gone has become endangered. To check the development of multiple foci the people should be notified, that approximate isolation may be provided before the infective stage begins. A notification is due the various school authorities. Should some exposed children attend a city school, the authorities there have a right to expect some notification, that the infection may be kept from among them. When those exposed have passed the minimum incubational period, they should be examined that the appropriate measures may be instituted. The known infected patients should be seen even before they are ill enough to require a physician. By the time their doctor sees them they have done the damage of infecting new households. The first patients to develop exanthems are the ones who most concern the public health official and should receive directions from him. The logical person to discover these early cases is the health officer. If the health officer would only find and isolate these, there would be fewer cases later. The early inspection checks the outbreak. The multitudinous inspections take much time, but it should be the purpose of the health officer to devote much time, his whole time, to the work.

With the perfection of state-wide organizations of whole-time health officers and the formation of the much-needed national Department of Health, a cooperative system will be developed, with relationships similar to, but with affiliation closer than, the state militia with the federal army.

ABSTRACT OF DISCUSSION

Dr. W. C. Rucker, Washington, D. C.: As nearly as I can sum up the paper, it means, first, that there should be persons who devote all their time to caring for the public health, and, secondly, that they should go about this in certain ways. Health work should be in the hands of professional health workers. There are too many "swivel-chair" sanitarians in this country. The people of this country are practical, hard-headed people, and when you do a thing they want to be shown why.

In a certain city in which I was once engaged in sanitary work, we were endeavoring to teach the people that it was dangerous to distribute garbage promiscuously. We had a large number of volunteer health officers, not medical persons at all, but persons who were engaged in this work as a social pastime and as a "temporicide."

I take issue with the first paragraph of Dr. Woods' paper. If I understand him correctly, he stated that the sanitary instinct of the people is retrograding. I think that the sanitary instinct of the people is just as strong as it ever was; but the fact is this—that when we get a crowd of people together in a small area, we are violating biologic laws; unless we throw around them certain protective systems, these people are going to die of their own excretions; and the task of the practical health officer is to protect people against their own excretions.

Dr. W. A. Howe, Albany, N. Y.: The more I see of this question of public health, the more I am convinced that the public health is a public business, and not a public philanthropy; and I think, as Dr. Rucker has just said, that too many people are meddling and interfering with things about which they know nothing. In New York State we have had our greatest trouble in financing our public health business. Last year $176,000 were available for the entire state of New York with which to look after the health of its people, exclusive of the city of New York. That amount for a great state like New York is too small. We are fortunate to-day in having a governor and a legislature who have looked at the price of public health from the right point of view. We are in a position now to divide the state into twenty districts and place at the head of each district a supervisor who receives $3,500 a year and devotes his whole time to the work of the district. We are also in a position to have nine divisions in our department and to place at the head of each division a director who will receive $5,000 a year for his services. Our commissioner will receive $8,000 per year, instead of the pittance of $3,500 with which he began. In other words, the state of New York to-day is recognizing the fact that the public health is purchasable and is getting ready to pay for it. If we fail in our work, the discredit will be to the administration of the health affairs of the state.

Dr. **Otto P. Geier**, Cincinnati: I believe the statement that the full-time health officer is paid in dollars and cents as well as in health is not arguable. In Cincinnati the salary of the health officer was raised from three thousand dollars to five thousand dollars. During the period in which this full-time health officer has been working the health appropriation has increased from fifty thousand dollars up to sixty thousand dollars. It appears, therefore, that that health officer on full time had been able to show the community that full time pays and that good health work pays.

We have a greater difficulty, however, than the one of proving that a full-time health officer pays, and that is, to entice the community into wanting a health officer on full time. We can agree that it pays, but how are we going to get the thousand and one communities of the country to see the truth of this principle? I do not know whether the American Medical Association owes that to the country, or whether it owes it to this section, but it seems to me that some propaganda should be started to induce communities to want good health.

One other point impressed me. I wonder whether we as hygienists are paying enough attention to the new movement of social service. If we desire morbidity reports that are worth while, then we must have these diseases reported. I believe in better cooperation between the social workers and the health department. The social-service worker, acting in cooperation with the health department, will bring forth cases which otherwise escape absolutely and which are foci of infection to the community. I believe, likewise, that the health officer can afford to put some emphasis on this subject just now, because in giving a better interpretation of his work and by injecting social service into the institutional life, the quarantine capacity of our hospitals is increased. In Cincinnati we have increased the capacity of our hospitals by excluding the unworthy cases, about 16 per cent., and have been able to take care of about 20 per cent. more cases of the fever and contagious type.

Dr. **J. N. Hurty**, Indianapolis: The all-time health officer is certainly coming. In Indiana the state board of health presented a bill in which it was provided that every county should have an all-time county health commissioner to serve four years. That is the time limit in our constitution. The bill, we thought, was a good one, well prepared, and well thought out. It did not pass. The opposition came from the health officers already in office, from the local league of medical freedom and the Christian Scientists. In order to secure all-time health officers, we must fight the present health officers. In Indiana every county has a county health commissioner, every city has a city health officer, and every incorporated town has a town health officer. Their duties and power are well defined. In all there are 643 of these officers. The new proposition of the board of health would cut them down to about 120. The increase of expense would be about sixty thousand dollars a year over what it now is. But two-thirds of the money now spent is wasted, because of inefficient health officers and too many of them, and because they do not give all their time to the work, but must earn their living practicing medicine. Until the present system goes, the very best health work cannot be done.

Dr. **Pauline M. Townsend-Hanson**, Marshalltown, Iowa: In order to get rid of the opposition of which Dr. Hurty just spoke and which will spring up wherever these health bills are introduced into the legislature, we do need the women; we need to have the lay public aroused, organized and educated. The profession must teach the lay public to become actively interested in public health work. In my own county (Marshall County, Iowa) there are from thirty-five to forty-five physicians; and in Marshalltown there are sixteen thousand people. I do not know the population of the county, but it is not for these thirty-five or forty-five physicians to say to the people, "You shall do this, that and the other thing for your health;" it is for us as physicians to teach them the scientific data that we know in regard to health, and for them to tell us what they will have. In an effort to get that arrangement, we have formed an association of the lay public for Marshall County. It is a representative body, composed of every organization in Marshall County that is willing to send delegates; and every organization in Marshall County not willing to send a delegate will be considered a custodial member of the Marshall County Health Association. This health association has a board of officers, and on this board of officers are represented the mothers' club movement, the women's clubs, political parties, churches, the schools and the medical profession. The call for a conference at which this organization had birth last month was signed by the president of the county medical association and by the county chairman of the Committee on Public Health Education Among Women of the American Medical Association. It was supported by the ministerial association, and by the county supervisors, and the county supervisors defrayed expenses.

It seems to me that an organization of that kind is an essential factor in furthering this work of sanitation.

Dr. **E. F. Otis**, Peñuelas, Porto Rico: We have accomplished in Porto Rico what has been forced on us by circumstances. I am heartily in agreement with Dr. Wood that there should be a local health service that is not governed through political influence; and I recommend the civil-service method. Thus far, we are getting splendid results. Education is one thing that we need in the management of the epidemics, and in order to secure that we must work with the people and be one of them, so far as we consistently can. This was illustrated in an epidemic of typhoid which we had in my town. The people were ignorantly prejudiced against all forms of sanitation when we started the work. We went right into their families and told them the dangers of the infection and how to avoid it. For those who were able to read, we posted the mimeographic copies of instructions about typhoid on the inside walls of the house and told them that it was their duty to read these instructions daily. By that means we gradually educated them. Afterward we obtained the support of the children. Whenever there was a sick person in the town the children would tell us about it. So by gaining their sympathy and support, we find that we are able to do much more than by emphasizing the official side.

Dr. **M. W. Richardson**, Boston: Dr. Wood spoke of the state inspection system in Massachusetts and of the salaries paid to inspectors as being from nine hundred to fifteen hundred dollars annually. That statement was erroneous. Our health district system consists of twelve districts, and the pay of the district inspectors, who are medical men in all instances, is approximately two thousand dollars a year. The state, however, does not at present require all the time of these inspectors and that is, of course, unfortunate. We hope, however, in the near future to obtain larger appropriations for this work so that we can command all the time of the inspectors and pay them more adequate salaries. As a matter of fact, our experience has been that these men, even under present circumstances, have given more and more of their time to the public health work and that their practice has actually gone to the wall. They have, therefore, given practically all their time to the public health work for a very small and inadequate compensation.

DR. HAROLD B. WOOD, Rochester, Minn.: It is an advantage not to take a practitioner of medicine who is licensed to practice in the state and gradually absorb him into the service, because people will many times request him to do medical service, thereby taking up his time. He should be so placed that he is not permitted by law to practice medicine within the state. The work of publicity must be frequent and constant.

OSTEOCHONDRITIS DISSECANS*

JOHN RIDLON, M.D.
CHICAGO

My excuse for reporting these three cases is that the condition is so rare that many eminent internists and general surgeons do not take it into account when considering the diagnosis of knee-joint trouble. Further, of the cases that have been reported, few have been presented in connection with roentgenograms showing typical conditions, and without roentgenograms I cannot well understand how a certain diagnosis can be made prior to operation.

REPORT OF CASES

CASE 1.—A man, 38 years old, was seen July 10, 1911. There has been trouble for three or four years in the left knee, though no cause for it is known. It is stiff after sitting and is sensitive at times. It has been materially worse for the past month.

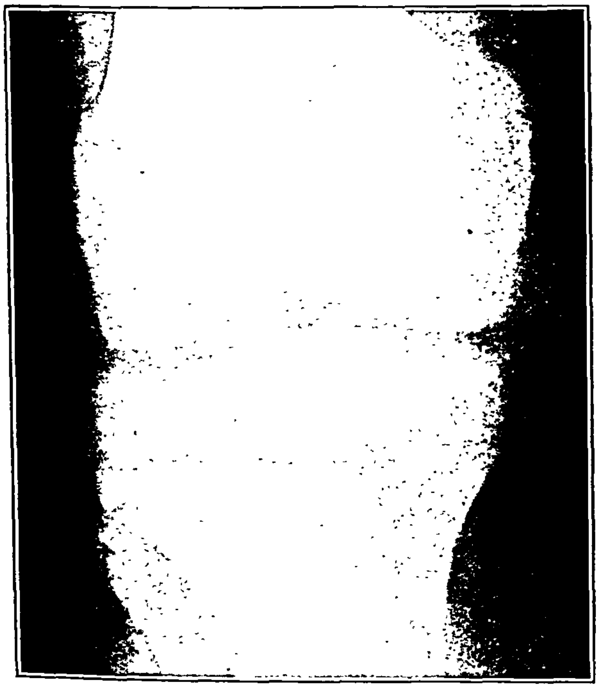

Fig. 1.—Case 1. Normal knee. Anteroposterior view.

Examination.—The patella floats, but does not "click." The midpatellar circumference of the left knee is three-fourths inch greater than the right; just above the patella it is 1¼ inches greater. There is no restriction of motion and no muscular atrophy.

The roentgenogram shows a typical piece as large as a prune pit at the bottom of the inner condyle of the femur. An operation for the removal of this piece was advised.

I discussed the case with an eminent general surgeon, who admitted to me that he had never seen or heard of the condition. I sent the patient to him for examination as a subject of interest. After the examination the patient reported to me that the eminent general surgeon had advised against an operation for the removal of the detached piece and had said in substance that he had cured many such knees by the injection of iodoform. Since then I have not seen the patient. Recently, March 30, 1913, the man wrote me that in August, 1911, the surgeon aspirated the knee and injected iodoform emulsion; after which he wore an elastic knee-cap. Eight months later, April, 1912, the knee puffed up again and became somewhat stiff and painful. The injection was repeated, May, 1912, a few months after that the knee was so much better that the patient discarded the knee-cap, and for a number of months the knee has felt entirely normal.

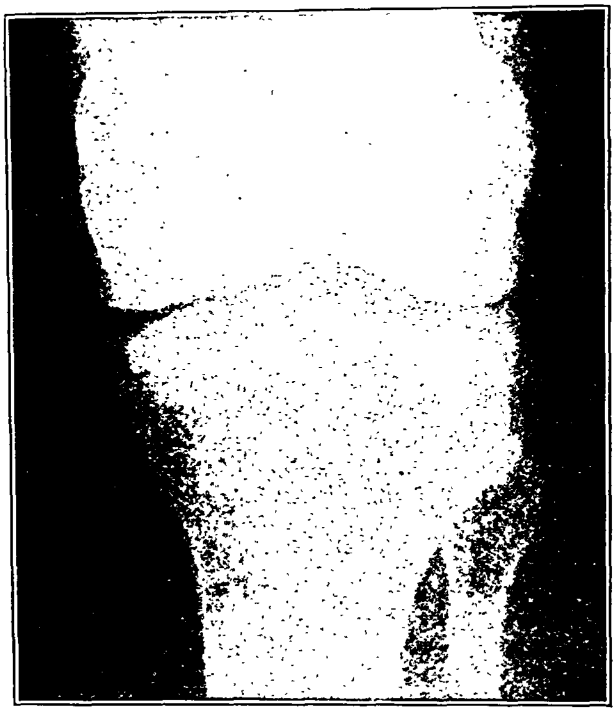

Fig. 2.—Case 1. Osteochondritic knee. Separated piece showing on bottom of inner condyle of femur.

CASE 2.—Man, 27 years old, was seen by my partner, Dr. Charles A. Parker, Aug. 12, 1911. For five or six years there has at times been a tendency to contraction of the right hamstring muscles. Usually the knee is not painful; but it is somewhat so during damp weather. The knee has never been swollen or stiff except as above mentioned.

Examination.—The patient walks with a limp and with the right knee held flexed at an angle of 15 degrees. The knee can be fully flexed, but lacks full extension by about 15 degrees. The site of the pain is along the side of the biceps tendon. There is no swelling; the leg measurements are identical. The man is a railway employee and jumps on and off a train without pain. The roentgenogram shows practically the same condition as in the first case.

Removal of the detached piece was advised; but the patient did not return, and has not replied to a letter of inquiry with regard to the present condition and what has been done for it.

CASE 3.—A man, 24 years old, the son of a physician, was brought under my observation in September, 1911. He first experienced trouble with the knee after playing hockey while in college some six years previously. The patient called the trouble "a throwing out." Just before I was consulted the knee had again given trouble while swimming.

---

* Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Examination.—The knee showed no swelling, no tenderness, no restriction of normal flexion and extension and no sensation was felt by the examiner's hand when the knee was flexed and extended. The roentgenogram showed a detached piece, not on the lower surface of the inner condyle as in the other cases, but on the outer aspect of the condyle. After viewing the roentgenogram it was possible to feel the detached piece which had before escaped our notice. An operation for its removal was suggested and was refused by the young man's father.

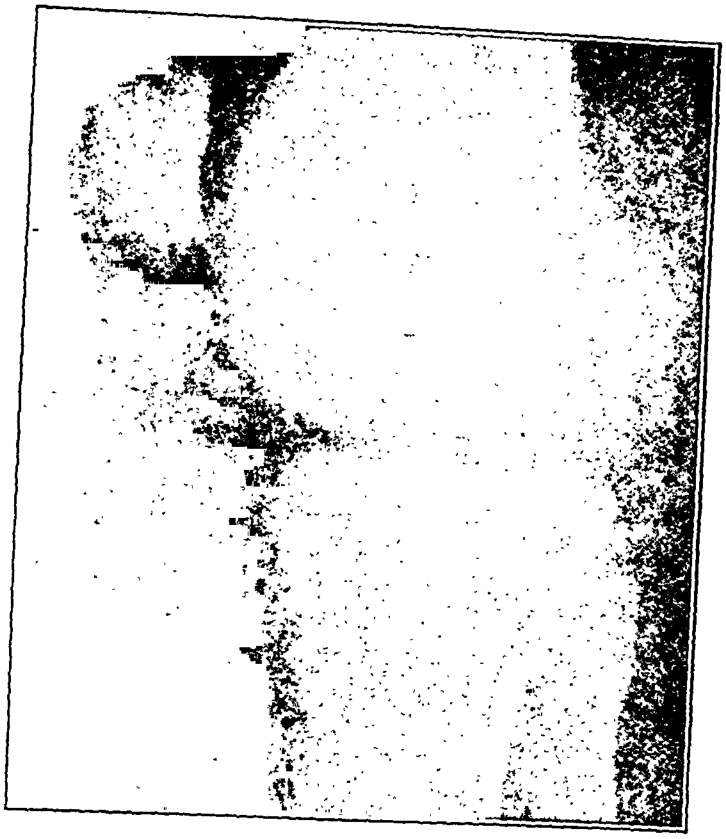

Fig. 3.—Case 1. Lateral view of normal knee.

March 4, 1913, the patient wrote that after my examination he wore a rubber knee-cap for some time and that the knee seemed well. But while in the Michigan woods last summer, some ten months after my examination, he often experienced a tightening of the cords and a kind of grinding sensation in the knee-joint after exercising freely. At the present time the knee seems to be practically normal except that it is about an inch larger than the other knee. This enlargement the patient thinks was present when I examined him, but my notes are lost and I do not remember that the knee was swollen.

Here, then, in three healthy, active and vigorous young men are three knees that have given trouble only a little throughout a period of many years; which show nothing save possibly a little swelling and a lack of full extension at times from contracted hamstring muscles; nothing on which to base a diagnosis until we come to a careful examination of good roentgenograms. Nothing is to be learned from the treatment of these cases except that they may go on for years giving little trouble. The treatment of the first case by the eminent general surgeon by aspiration and injection of iodoform is too absurd to warrant comment.

SUMMARY

Now let us consider for a moment what is known and thought by others about osteochrondritis dissecans, what has been done and with what results. My attention was directed to this condition by Freiberg's very complete report of a case.[1]

Freiberg's patient was a girl, 20 years old, having trouble with both knees. There had been pain and frequent joint-locking since childhood. At 17 years of age, while in Russia, both knees had been opened and loose bodies removed, which were afterward seen by the patient. A second operation became necessary because of the appearance of more loose bodies. No roentgenograms were made in Russia. These operations afforded relief. At no time had there been any injury to the knees that was remembered. On examination by Freiberg pain was complained of in walking, but more on standing. The right knee was more troublesome than the left. Both knees appeared to be somewhat swollen, but both had normal motion. There was no muscular atrophy and no crepitation or grating on motion in either joint.

Roentgenograms showed two separated pieces on the lower surface of the inner condyle of the right knee. The roentgenogram of the left knee showed no loose pieces, but the lower surface had lost its normal convexity and was somewhat concave, and the condyle had lost somewhat of its vertical bulk.

When the right knee was opened a loose body, the size of a cherry, was found, attached to the inner condyle by a slender pedicle of connective tissue and synovial membrane. This was removed. Nothing was seen of the two fragments shown in the roentgenogram or of the defect of the inner condyle. The cartilage appeared of different color here than elsewhere, and pressure on it seemed to indicate that it was loosened from the underlying bone. This was left alone, as Freiberg at that time did not know that Ludloff had cut through the cartilage and removed the loose fragment in a similar case. In the left knee no loose body was found. The mesial condyle of the femur appeared unusually flat and somewhat irregular in surface, but was covered with cartilage of normal appearance.

Ludloff[2] (still quoting from Freiberg) reports two cases in which the diagnosis was based on the roentgenogram and was confirmed by the operation. In both cases the roentgenogram showed a body about the size of a date-seed which had apparently separated from the inner condyle of the femur opposite the insertion of the posterior crucial ligament. It appeared to lie in a cavity hollowed out of the condyle. In the first case the cartilage was intact over the body and it was liberated only by incision; in the second case a part of the

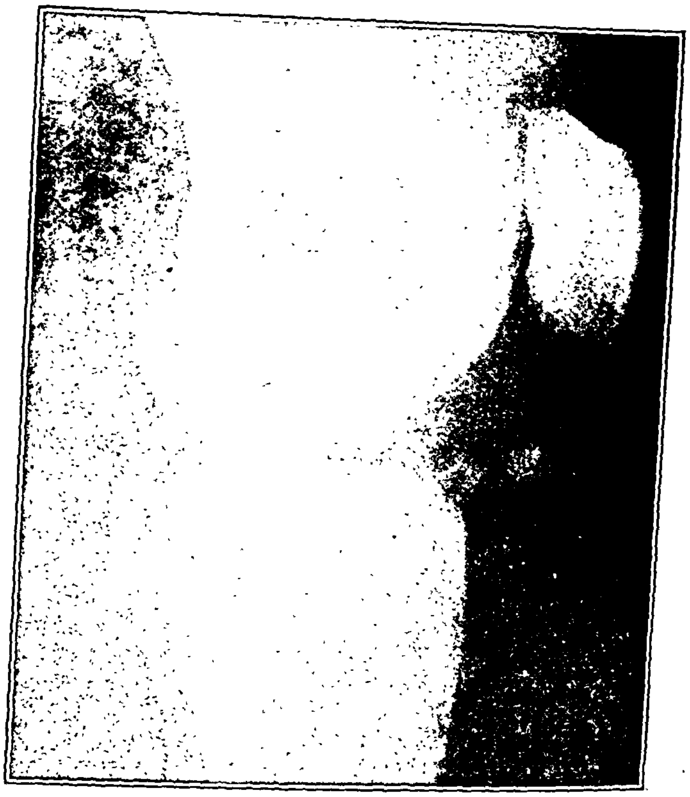

Fig. 4.—Case 1. Lateral view of osteochondritic knee, showing separated piece on inner condyle.

bone fragment had already separated as a free body. In this case the other and supposedly normal knee presented in the roentgenogram a similar condition.

Freiberg credits Koenig[3] with the first description of this knee-joint affection and the name. It appears to the writer that our present knowledge of this condition does not warrant us in discussing its relations to other loose and partially detached bodies in the knee-joint, or to its possible relation to osteo-arthritis.

72 Madison Street.

ABSTRACT OF DISCUSSION

Dr. Albert H. Freiberg, Cincinnati: I think that the first two cases Dr. Ridlon showed are typical examples of this condition, and I consider it safe to prophesy that, if we may follow these cases, it will be found that loose bodies will appear in both of them eventually. A great many years ago, Koenig suggested the existence of a distinct and separate disease to which he gave the name of osteochondritis dissecans as the explanation of loose bodies, particularly in the knee and the elbow, for which no other explanation previously given had proved to be adequate. Previous theorizing on the subject had been unsatisfactory. These bodies had been supposed to be due to the coagulation of fibrin in the synovia of the joint, to the knocking off of some pieces by traumatism, etc.; but that they resulted from a distinct and separate affection of the bone and cartilage had not even been suggested by any one before his time. Koenig's conclusions had been arrived at as the result of the examination of these knees during operation. It seems to me perfectly evident that we have here a distinct disease, which presents characteristics unlike those of any other disease of the joints which we encounter. I do not think that the disease can be considered osteo-arthritis simply. It was the view of Dr. Woolley and myself, as the result of the pathologic examination of the material from this knee, that it was likely that vascular changes should be regarded as the causative factor in the production of the condition and the loose bodies that resulted.

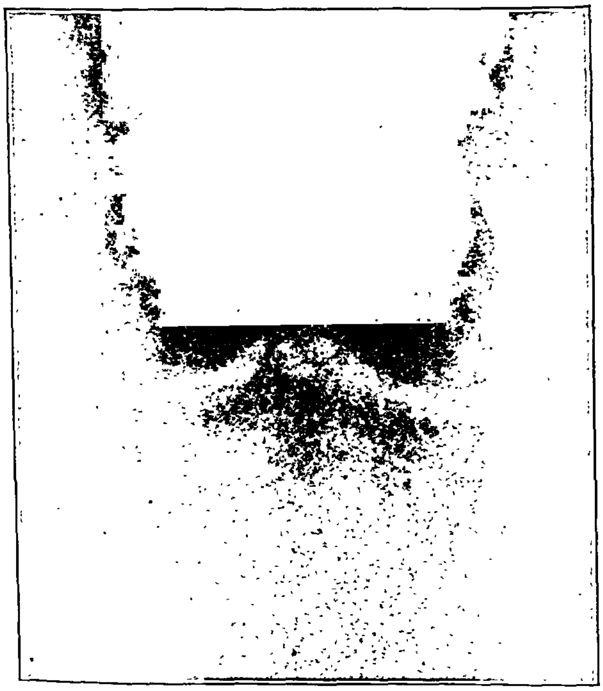

Fig. 5.—Case 2. Separated piece on bottom of inner condyle.

The question of what should be done for a patient giving the history of the condition that these patients of Dr. Ridlon present, with no condition calling for the opening of the joint and the removal of the loose body, is a matter on which there may well be some doubt in our minds. It is not inconceivable, however, that bodies that have been loosened from their surrounding bases, as these have been, as the result of the pathologic process may again become adherent, and that therefore loose bodies need not necessarily result. I should consider that if a person were in a walk of life that would call for a considerable use of the knee, so that attacks such as Dr. Ridlon has described would occur frequently, it would be justifiable to open the knee and remove the offending material. The operation would not be other than an ordinary arthrotomy in any of its characteristics, I believe.

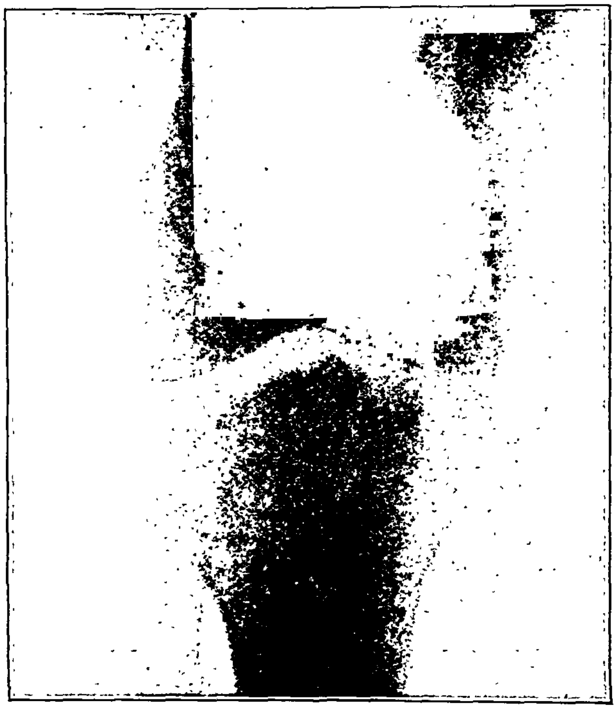

Fig. 6.—Case 2. Normal.

Dr. R. T. Vaughan, Chicago: Last year I saw a case with Dr. A. E. Halstead in which we operated for a foreign body in the superior recess in the knee. After we took it out, we found that on one side it was distinctly bony and on the other cartilaginous. On making a more careful examination of the roentgenogram, we discovered a little indentation, shaped like the foreign body, over the internal condyle of the femur. On looking up the literature of the subject, it seemed to me that such foreign bodies have been interpreted in the past as quite pathognomonic of arthritis dissecans; and we so considered this case, although we had no further evidence as to its possible etiology beyond the early trauma.

Dr. Emil S. Geist, Minneapolis: I should like to ask Dr. Ridlon how he explains the symptoms in the case he cites in which, if I understood him correctly, there was no apparent destruction of the articular cartilage.

Dr. John Ridlon, Chicago: In answer to Dr. Geist, I do not know why these joints with the cartilage apparently normal on the surface have symptoms.

As to the tibia, I know my anatomy well enough to know that the top of the tibia has terminal arteries, as I am told the internal condyle of the femur also has.

Dr. Albert H. Freiberg, Cincinnati: Lexer's work shows that there are terminal arteries in the upper end of the tibia. It is the same in the elbow. That is the explanation of the fact that most loose bodies are found in the knee and the elbow.

Dr. John Prentiss Lord, Omaha: I am reminded of a case that I reported some years ago, in which there were eight large bodies of this kind in a joint, and the symptoms had become so distressing that the patient was unable to carry on his occupation and was incapacitated for months at a time. The bodies were so large and irregular and were so placed that the only way in which I could remove them was by dividing the patellar tendon, opening the joint wide and turning it backward. It was then only with difficulty that I could remove the bodies from behind the condyle. The radical operation for the relief of the condition in this extreme case was rather unprecedented, and the result was ideal. There was perfect primary union and perfect restoration of function. The case was extraordinary on account of the size and number of the bodies.

---

[3] Koenig: Deutsch. Ztschr. f. Chir., 1888, xxvii, quoted by Freiberg.

Dr. Albert H. Freiberg, Cincinnati: The process in which a large number of free bodies are found in the joint is different from this process of osteochondritis dissecans. That arthritis deformans or osteo-arthritis results in the production of large numbers of free bodies in joints has long been known. There is no discussion as to their nature. When there are eight or ten, or from fifty to one hundred, of these bodies, the cases are osteo-arthritis; the pathology is perfectly apparent, and we usually find the other changes of this disease.

Dr. John Prentiss Lord, Omaha: I am fully aware of the point that Dr. Freiberg has made. I had an opportunity to have the joint wide open and could see the various points on the articular surface—particularly on the condyles, one part of which was flattened by the casting off of these bodies. They were of such irregular bony consistency that they were entirely different from ordinary joint mice, so-called. In connection with the same paper, through the courtesy of the late Dr. Bernays, I exhibited a pint bottle containing 580 bodies of this kind, which were quite large. They were all polished, however, and were evidently produced by the process that Dr. Freiberg has referred to. It seems to me that the condition found in that joint would indicate that my case was of the particular type under discussion.

RESULTS OF BONE PLASTIC AND GRAFT OPERATIONS ON THE SPINE FOR THE CURE OF POTT'S DISEASE *

JOHN JOSEPH NUTT, M.D.
NEW YORK

In assuming the position of surgeon to Sea Breeze Hospital in November, 1912, I received under my care ten patients who had been operated on for tuberculous disease of the spine. Five other patients who had been operated on and discharged have been examined by me, some of them several times. Thus I have had the opportunity to study the results in fifteen cases.

Fully realizing the importance of correctly interpreting these results, on account of the influence this report may possibly have in either deterring others from or encouraging them to adopt these operations, I have attempted a tabulation of all the factors which are of value in reaching a conclusion in each case and present copies of the tracings of the kyphoses taken from the history sheets. After a study of the temperature charts, it did not seem worth while to reproduce them. The rise and fall for months before the operation was in each case almost identical with the curve as charted for months following the operation. I worked out some of the averages. One case, for instance, had an average temperature for August, 1911, of 98.94, and for August, 1912, of 98.77; in Case 4 the average for May, 1911, was 98.8, and for July, the month following the operation, it was 99.2. Those who were running rather high temperatures before the operation, continued to do so afterward. Nor did a study of the changes in weight of these patients throw any light on the success of the operation; there were no great changes except in those who did remarkably poorly.

The plastic operation consisted in splitting the spines of several contingent vertebrae in a plane coincident with the anteroposterior mesial plane of the body, fracturing these split portions near their bases, bending one-half of each spine upward and the other half downward and with sutures securing each half to the opposite half of the vertebra above or below, as the case might be.

The graft operation consisted in transplanting a piece of bone from the tibia of the patient to a bed made for it by splitting the spines of the vertebrae to be immobilized.

Case 1.—The patient had treatment for one year and nine months before operation. Tracings show some increase in deformity but the patient was without orthopedic treatment for three months while in another hospital for scarlet fever. At the time of operation the disease seems to have been under control. Nine months after operation all protection was removed. Four months later stiffness of the muscles was noted in the history and soon afterward frame treatment was resumed. The patient is at present wearing a jacket.

Case 2.—The patient had marked kyphos when admitted. The general condition was good; there was no muscular spasm and no sign of abscess. Treatment was with Calot jacket. The child did not stand well and two months prior to operation was placed on a frame. Eight months after operation protection was removed. One week later: "Child walks somewhat awkwardly but has no pain. Spine flexible except region of operation where it seems rigid." Seventeen months after operation: "No sign of local activity although child rests herself with hands on knees occasionally. To be kept in bed one-half of each day." One month later, Oct. 1, 1912: "Has grunting respiration. Plaster-of-Paris jacket applied."

Case 3.—The patient was under treatment for four years and eight months before operation. There is no history of abscess formation or evidence of the disease not being under control. Following operation a plaster jacket was worn for eight and a half months. Eight months later the patient was discharged. Examination Jan. 9, 1913, showed some increase in deformity, but no evidence of muscular spasm.

Including the eight months' plaster treatment subsequent to the operation, this spine was treated by apparatus for over five years and, taking into consideration the absence of any history notes pointing otherwise, it would seem to be a reasonable conclusion that the disease was arrested; certainly the spine was in excellent condition, and, as the deformity increased after the removal of all support, the benefit of the operation in this case is doubtful.

Case 4.—Examination on admission: "Condition fair. Stiffness in upper part of spine. No sign of abscess. Lymph-nodes enlarged on both sides in cervical and axillary regions."

History would indicate that treatment was not efficient. Examination, April 15, 1913: "General condition poor. Has had whooping-cough since discharge from hospital. Grunting respirations. Deformity increased."

Case 5.—The patient was admitted a few days after operation. History notes were indicative of progress until March 26, 1912: "Spine O. K. No spasm. Spasm of left psoas. To be kept in bed. Some thickening in left iliac fossa."

October 15: "Psoas contraction nearly disappeared. No abscess tumor can be felt. Is running about without symptom."

Nov. 7, 1912: "Limited extension of left thigh. Discharging sinus. Walks with difficulty and every evidence of apprehension."

Case 6.—On admission: "In good general condition. Marked kyphos dorsolumbar region. Spasm and rigidity of back muscles."

After two and one-half years' treatment: "General condition excellent. Considerable recession of kyphos."

Postoperative notes show spine to be in good condition.

---

* Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

RESULTS OF OPERATION IN FIFTEEN CASES OF POTT'S DISEASE.

	Location of Infection. Admitted.	Age on Adm. Yrs.	Duration on Admission. Mos.	Length of Hospital Treatment before Op. Yrs.	History Note before Operation.	Condition at Time of Operation.	Date of Opera'n.	Nature of Oper.	Time after Op. all Protection Removed. Mos.	Length of Hospital Treatment after Op. Mos.	Time after Operation and Nature of First Sign of Insufficient Protection.	Present Spinal Aprts.	Deformity Increased as Shown by Tracing.	Muscular Spasm Present.	Operation Beneficial.
1	11 D.—1 L. 6/26/09	2½	6	1¾	3/9/11. General condition good. *Still on br'd frame.* Spine fairly flexible each side of kyphos.	Fair	4/ 1/11	Plastic	9	‡	6 mos. *Peculiar walk*	P. P. J.	Yes	Yes	No
2	9 D. 6/21/09	3	?	1¾	12/29/10. Spine fairly flexible each side of kyphos. Ordinary jack app. Stands with hands supporting head. 2/25/11. J. fails to support well. Placed on frame.	Fair	4/ 1/11	Plastic	8	‡	5 mos. Supports with hands on knees	P. P. J.	Yes	Yes	*No*

10	11 D. 2/28/10	5	6	1¼	2/17/12. Kyphosis *increased since last tracing.* Spasm marked when passive motion attempted. *General condition good.*	Acute	5/25/12	Graft	2	‡	6 mos. Psoas spasm	Brace	Yes	Yes and abscess	No
11	9-10 D. 6/26/11	2	9	1 1/12	10/21/11. Local condition much improved. Kyphosis *much less prominent.*	Excellent	7/15/12	Graft	2	‡	No return of sign or symp.	None	Yes	....	Yes
12	12 D.—1 L. 7/21/10	6	24	2	12/30/11. Considerable recession of kyphosis. To obtain permission to operate.	Fair	7/19/12	Graft	1½	‡	10 wks. Stiff walk	None	Yes	Yes	Doubtful
13	Dor.—Lumb. 5/28/08	4	12	4 1/6	4/9/12. Hip very sensitive to all attempts at passive motion. *Limb held in flexion and adduction.*	Arrested	8/12/12	Graft	‖	‡	No return of sign or symp.	*Hip* traction	*No*	....	No
14	8 D 8/22/05	3 (for T. B. knee)	?	†	7/09. Discharged; wearing jacket. 2/13/10. No increase of deformity. No evidence of active disease.	Arrested	6/10/12	Graft	1½	**	No return of sign or symp.	None	No	....	No
15	12 D. 5/3/12	5	?	*	5/26/11. Readmitted. Notes concern the knee.	Unknown	4/ /12	Graft	§	5	1 mo. Awkward walk	None	No	Yes	Yes

* Operation before admission.
‖ *Bed treatment continuous.*
¶ Still under treatment (for a mastoiditis).
† Spine infection one year and four months after admission. Operation six years later.
§ Without protection since admission.
‡ Still under treatment.
** Under observation for knee.

Case 7.—The patient received four years' and three months' treatment before operation. The history during this period gives no evidence of anything but satisfactory progress. Tracings show a remarkable increase in deformity between Feb. 16, 1911, and May 25, 1911, without any explanatory note. From this history I judge that the disease was arrested at the time of the operation, and subsequent tracings show that the operation failed to prevent increase of deformity.

Case 8.—After being in the hospital for two years and three months the patient was pronounced cured and ordered discharged wearing a jacket. She was retained, however, and was operated on. There are no notes indicating a return of the disease. All that the operation could have been expected to do in this case was to do away with the necessity for any external support of the weakened spine. In this it was a failure.

Case 9.—The patient was admitted immediately after the operation. An interesting point in this case is found in the tracings. December 12, the patient was placed on a frame and a month later the tracing showed a marked recession of the deformity. She was then allowed to be up without protection for a month, and a tracing at that time, February 16, showed the deformity to have again increased. (Figs. 1 and 2.)

Case 10.—On admission: "Marked kyphos at second dorsal. Spasm of back muscles. No sign of abscess. Glands normal." History prior to operation gives no indication of abscess formation. On account of the note three months before operation, I have classed this as an acute case.

Oct. 8, 1912, five months after operation: "Wound has remained healed (there had been a stitch abscess). No evidence of active disease or lack of support. Has been up and about since eight weeks after operation."

Nov. 7, 1913: "Left psoas contraction. Tumor in left iliac region. Discharging sinus lower end of dorsal wound. Apprehension marked." (Graft 5 by ½ by ⅓. Figs 3 and 4.)

Case 11.—History notes of this case show that the improvement before operation was marked. April 16, 1913, nine months after operation and seven months after removal of apparatus: "General condition excellent. Extension of left thigh may be slightly less than right. Tracing shows deformity to be slightly increased." It might seem wiser to withhold a verdict in this case for several months.

Case 12.—Six months after admission and six months before operation: "Local condition improving rapidly. General condition excellent. Spine flexible each side of kyphos." Four months after operation: "Movement in lumbar region, below site of operation, limited. Some restriction of extension of the thighs."

Case 13.—From the history it would seem that the spine had been in excellent condition for about a year before the operation and that the hip was demanding the most attention. Nov. 7, 1912: "Spine evidently in excellent condition. Hip shows spasm in extremes of motion. Patient has been in bed continuously since operation."

Case 14.—The patient was admitted for tuberculous knee. Pott's disease was discovered one year and four months later. History points to the knee having been at all times the more serious focus. No active symptoms are recorded in connection with the Pott's disease. It can scarcely be doubted that the spinal infection was arrested at the time of the operation.

Case 15.—The patient was operated on shortly before admission. Fifteen days after operation: "Walks awkwardly. Plays about." April 15, 1913, about one year after operation: "No increase of deformity. Walks awkwardly. Slight spasm of right psoas." We have but little information about this case. Probably a final verdict should not be offered for at least another six months.

CONCLUSIONS

1. While I do not unqualifiedly condemn the operation on account of the poor results in some of these cases, I do not believe the claims which have been made for it have been substantiated (see illustration from Annual Report of Sea Breeze Hospital).

2. If alterations in technic, such as the implantation of a longer graft, and the extension of the period of postoperative use of external support, are to improve the results, then reports should be forthcoming two years after the operation and not before.

3. The danger in the use of the operation does not lie in the operation itself, but in the creation of a sense of false security, a feeling that a cure of a chronic disease has been produced, and a consequent neglect of other therapeutic measures.

2020 Broadway.

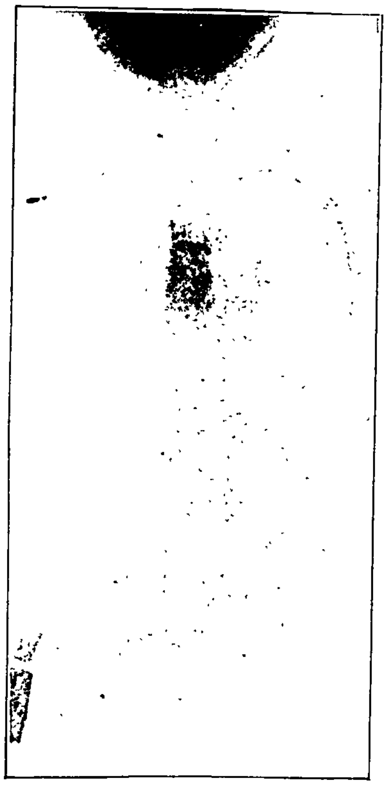

Fig. 1 (Case 9).—Roentgenogram, taken in May, 1913.

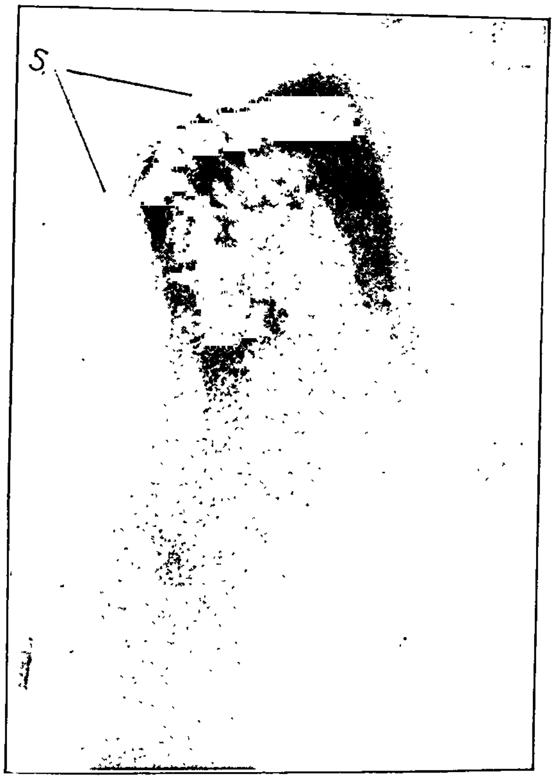

Fig. 2 (Case 9).—Roentgenogram, taken in May, 1913. Present activity of the infection, fourteen months after operation, is clearly shown in these two pictures.

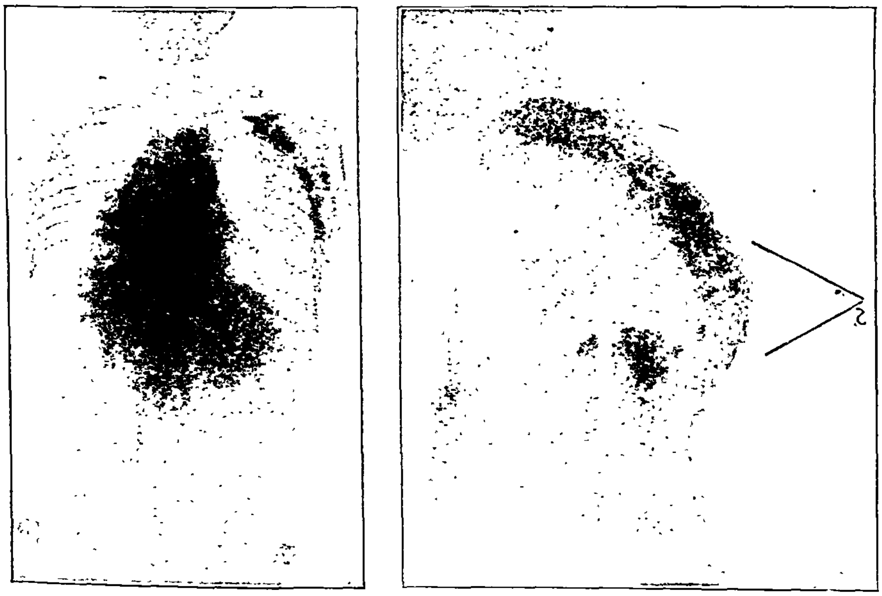
ABSTRACT OF DISCUSSION

Dr. John Ridlon, Chicago: The report of Dr. Nutt is a word of caution that it is well to have spoken. We cannot expect, by any operation, or by any maneuver or any method of treatment, to cure all these patients or have them all do well. Some will do badly, whatever we do in an operative or a non-operative way; and no one should be so enthusiastic over his own method of treatment as to lead the general public or the general practitioner to believe that all patients can be rapidly cured by this one method of treatment.

Dr. Reginald H. Sayre, New York: In the various cases that are noted in Dr. Nutt's report, if you will look at the tracings, you will see that almost all had distinct improvement in position in the tracing taken immediately after operation, as compared with the tracing taken immediately before operation. Little by little, however, this curve became more pronounced until, in a good many instances, the result within a year or eighteen months after the operation was still more curve than had existed prior to the operation. In a case that I have observed, in which one of my colleagues operated in my service while I was abroad last year, no protective support has been applied. I did not put any protective support on the patient when I came back, being anxious to see what would happen. The spine of the child gradually became more and more curved, and the roentgenograms taken at intervals of from six weeks to two months showed progressive degeneration of the inflamed part of the spine; there was more loss of substance in the inflamed part of the vertebrae than was present a year ago, showing that the operation itself has not caused a change in the diseased part of the vertebrae. Disintegration has gone on, just as it would have done if the vertebrae had been left alone; although the splint has probably prevented as much curving as the child would have had if not operated on. The condition became painful, and the child was put in a wooden frame. The spine has now begun to straighten once more. I believe that while these operations are, in selected instances, wonderful advances, they will not relieve us from the necessity of protecting these vertebrae for a long period of time. I think, however, that perhaps it may be wise not to use protection in these cases for a while. Let us find out whether we change the pathologic process, so that instead of having a disease which ordinarily continues for two or three years and requires protection during this period, there is a normal condition secured by giving physiologic rest with bone-splints for six or eight weeks.



Figs. 3 and 4 (Case 10).—These two roentgenograms, taken in May, 1913, one year after operation, of a patient with no history of abscess formation previous to operation, illustrate what may result from this treatment as at present carried out.

If this is so, it is a wonderful advance, and let us know it; but, so far as my experience has gone in the case under my supervision, I do not believe that the operation does that. I think that we must continue the protection, as before.

Dr. F. J. Cotton, Boston: For fourteen months past I have been doing some work on bone-grafts with Dr. Loder, my assistant, dealing particularly with the transplanting of the condyles of the femur, and the study of the ideal process of the life and growth of the bone-transplant under the best conditions.

The conditions include absolute asepsis, a sufficient serum supply and absolute fixation. About one hundred operations were performed, on seventy-five subjects, partly cats and partly rabbits. The same process occurs in transplants as in isolated bone fragments. The bone promptly degenerates; the bone corpuscles practically all disappear. The ideal process of repair depends on the life of the osteoblasts, which promptly form a perfectly definite layer of cells next the bone, and immediately begin to lay down new bone. The dead or degenerated trabecula is immediately clothed with new osteoid tissue; the old bone is necrotic in a sense, but not in the sense that it gives rise to any irritation whatever. On the other hand, if there are not sufficient osteal cells to form new bone, the result is a destructive process, with the appearance of osteoclastic giant-cells.

I do not think that, clinically, we can say much about what is going on in a histologic sense in any given case.

You can transplant cartilage without any chance of loss, if it is clean. If you have spongy bone, with a maximum of osteal cells and transplant a minimum of relatively nonviable trabeculae, you have a transplanting of active cells on a permanent scaffolding; and whenever these osteal cells get a fair chance they clothe the trabecula in that way. On the other hand, whenever they do not get a fair chance, a prompt giant-cell erosion takes place and the cells are absorbed. The appearance of the Haversian canals and a remodeling of the bone, which takes months in the human being, occurs later. That is not a part of the union of the graft with the host bone, but a remodeling to adjust the structures to strain. It is accomplished under Wolff's law, I think; and it is not fair to call it a part of the union of the graft, either histologically or clinically.

I am treating this from the experimental side. I believe that we shall find that a graft that is good for anything clinically will be a graft of spongy bone. I am not inclined to feel that the grafts made of dense bone will be a valuable source of new bone, although they live. I have used that sort of graft in a number of cases and cannot feel that these cases did any better than if a bone knitting-needle had been used in the same way. I started with a different notion; but I have become enthusiastic about the growth of spongy bone, and not about the other. Dr. Loder and I are not yet ready to make a full report. It seems, however, that we have gone far enough to demonstrate a certain law of growth under optimum conditions.

Dr. D. B. Phemister, Chicago: The influence of infection on the transplant has been spoken of. I have noticed that its presence does not always mean a failure of the operation. If the infection is severe and quite extensive, resulting in marked exudation or suppuration, the entire transplant will die and have to come out. But if it is milder and confined to a small portion (nearly always one end of the transplant), then that part only will undergo necrosis. The effect of the infection on that portion which "takes" frequently is that its periosteum is stimulated to excessive callus formation, producing an involucrum on the transplant just as we see it in the ordinary case of osteomyelitis. In such cases, if the portion which dies is not absorbed after some weeks or months, it can be removed.

Dr. F. H. Albee, New York: Dr. Nutt is keen on drawing conclusions from history charts alone. He draws the conclusion in most of these cases that the patients were cured. He says that in one case there was scarcely any doubt that there was a cure, yet he never examined the patient before operation. He took charge of the hospital long after the operation had been performed. I think that it is wrong to draw such conclusions from history charts. Dr. Ely was there before I was and neither of us is expert on writing out histories of cases. We made short notes; but to take these and draw conclusions from them is not just. I talked over the cases with Dr. Nutt, but my word was entirely ignored as to the condition that had existed before operation.

The roentgenogram does not cover the complete area of the disease. Neither did the grafts, yet they held perfectly the vertebrae in which they were situated. The deformity did not occur in the vertebrae held by the graft, but below that point. I have had other cases that came under the the care of other men. I have had two such cases that came under the care of one other man, in which the plaster jackets were immediately put on. Fortunately they came back to me. I took off the jackets and the patients have done well ever since. I do not think that the fact of Dr. Nutt's putting jackets on the patients is a trustworthy reason for considering that the operation is not a good one.

The operation on these vertebrae is not contrary to any orthopedic law, but in accordance with all orthopedic principles. We feel certain that we can fix the vertebrae and I doubt whether having patients with Pott's disease try to flex their spines will reveal whether three or four vertebrae are fixed together or not, as I have patients with very flexible spines in whom it would be very difficult.

Dr. Sayre points out that in many cases the deformity has progressed since the operation, in some cases to where it was before operation. I think some of this deformity is due to a lack of growth of the vertebral bodies on each side of the disease process. One picture shows markedly wedge-shaped vertebrae which apparently were not involved by the process in the diseased vertebrae, producing an atrophy and lack of growth of the vertebrae, as it does in the hip. We put patients with these wedge-shaped vertebrae on a frame so that the bodies came together again. Some of the deformity is due to lack of growth in the piece each side of the kyphosis.

It would be more conclusive, of course, had we another very excellent treatment to compare with this treatment. We might take, for instance, the special case treated in the hospital Dr. Nutt now has control of, in which the patient was put on a Bradford frame, the picture having been published showing the patient as cured. He was on a frame two years, then wore a plaster jacket two years. After going without the jacket for a year he had a relapse. So far as I know he is still wearing a brace made under my direction.

Judging from results obtained from ankylosing operations at the knee and other joints I believe we shall find that bone fixation has a marked effect on tuberculous disease of the joints.

Dr. John Joseph Nutt, New York: This patient of whom Dr. Albee spoke as having had the relapse, I did not see at the time, but I did see him on several occasions this winter. He is wearing a spinal support, looks well and attends school regularly.

I had the roentgenograms taken only a few days ago. I did not lay much stress on them, because they cannot assist much in determining whether the patients relapsed or did not relapse. I am not discussing the technic of the operation.

CHARCOT JOINTS AS AN INITIAL OR EARLY SYMPTOM IN TABES DORSALIS *

HENRY LING TAYLOR, M.D.
Professor of Orthopedic Surgery, New York Post-Graduate Medical School and Hospital; Assistant Surgeon, Hospital for the Ruptured and Crippled
NEW YORK

The considerable number of cases observed by me in the last few years, in which a Charcot joint or a spontaneous fracture has called attention to an underlying tabes long before any ataxia was evident, has lent new interest to this heretofore rather unpromising class of cases. This interest has been intensified by the excellent results obtained from proper splinting and orthopedic treatment in both fractures and Charcot joints, which in many cases have enabled the patients to resume their work.

The material on which this paper is based consists of twenty-three cases of Charcot joints observed in the last few years in clinic and private practice. Of the twenty-three cases, twenty-one were in men and two in women. The ages of the patients when first seen ranged from 29 to 57. One patient was 29, eight were from 30 to 39, ten from 40 to 49 and three 50 or over; in one the age was not ascertained.

CAUSATION

Twelve patients definitely admitted luetic infection and an initial sore; four admitted gonorrhea but denied syphilis, and two denied both. In five the history of infection was not gone into. In most of the eleven cases without a syphilitic history, a positive diagnosis was extremely probable on clinical grounds, and it is my firm conviction that a luetic infection is the underlying cause in every case. It is interesting to note that in the twelve cases in which the date of the initial lesion is known, syphilis was acquired in every instance between the ages of 18 and 25. The shortest period noted between infection and a Charcot joint was seven years; more commonly it appeared from fifteen to twenty years or more after infection. The Wassermann reaction is not always positive, especially in those cases in which antisyphilitic treatment has been given. Stein's statement[1] that tabetic patients who have never been treated for syphilis always give a positive reaction, if confirmed, practically proves the syphilitic basis of all tabes.

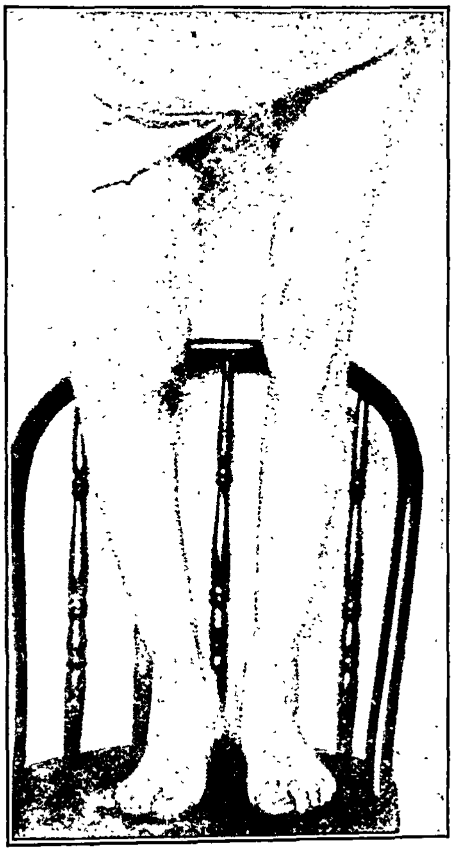


Fig. 1.—Case 5; right Charcot knee.

A number of patients attribute the beginning of their symptoms to a definite trauma, even when there is no immediate fracture or joint lesion. Many more say that an injury which proved to be a fracture was soon followed by painless or nearly painless swelling of the involved or neighboring joint. Crush fractures of the outer or inner tibial tuberosity, often spontaneous, painless and unrecognized, are a frequent cause of a Charcot knee. Doubtless the tabetic joint with effusion and bone softening precedes in many instances, resulting later in a spontaneous crush fracture after joint involvement. Seven of the cases here reported suffered practically painless spontaneous fractures before the Charcot joints appeared. These and others have already been reported[2]

---

* Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[2] Taylor, H. L.: Med. Rec. New York, Oct. 26, 1912; Post-Graduate, November, 1912.

in detail. In the twenty-three cases here considered there were three spontaneous fractures of the shaft of the left femur high up, one of the right patella, one above the right ankle, one of the neck of the right astragalus, seven of the internal tuberosity of the tibia (four right and three left) and one of the right external tuberosity; all were followed by a Charcot of the implicated joint. Nearly all tabetic fractures heal kindly with a large callus after the usual splinting, which should, however, be somewhat longer continued than in ordinary cases.

DIAGNOSIS

Spontaneous fractures and Charcot joints often occur in patients who have noticed no previous disturbance in gait, and have considered themselves in good health. A painless fracture or large persistent joint effusion with joint looseness, but with little pain or local disturbance in adults, should always lead to examination for the symptoms of tabes dorsalis, when Westphal's sign (absent knee-jerks), pupillary symptoms, and swaying with eyes shut (Romberg's sign) will usually be found, even when there is no ataxia.

In one instance a man aged 49 slipped and ruptured the left quadriceps tendon, which was sutured and united with good function. He had had a perforating ulcer under one great toe for six months, and still had it when seen a year later. Examination showed knee-jerks absent, fixed small pupils, Romberg's sign and vesical crises. He undoubtedly had tabes, which was the underlying cause of the quadriceps rupture as well as the ulcer. There was no subsequent Charcot joint.

The commonest of the early symptoms of tabes are shooting pains in the trunk or limbs, for which the usual treatment is that for rheumatism or neuralgia, or even for local troubles. I know of a man who had difficulty in walking in the dark, who was treated two years by a leading specialist for stomach trouble and visceral ptosis, when his symptoms were due to the gastric crises of tabes. Another man, a wealthy American who had four abdominal operations for supposed stomach and intestinal conditions, without benefit, was diagnosed at a glance by Oppenheim in Vienna as having tabes dorsalis. His pains had been due to this infection. In another case a tabetic joint was diagnosed as sarcoma in a London hospital, and the leg amputated. Adults, especially men complaining of persistent shooting pains, should be examined for tabes. Bladder symptoms and ophthalmoplegia are also occasionally early symptoms of tabes.

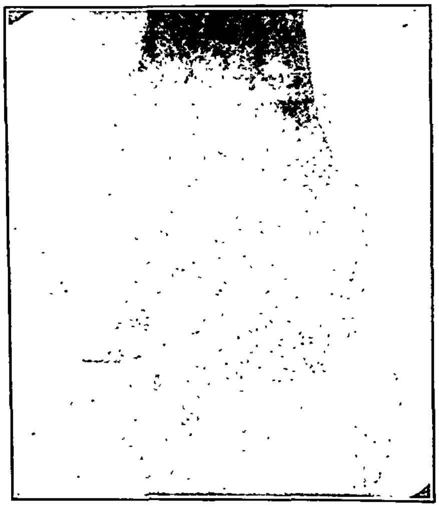

Fig. 2.—Case 5; right Charcot knee.

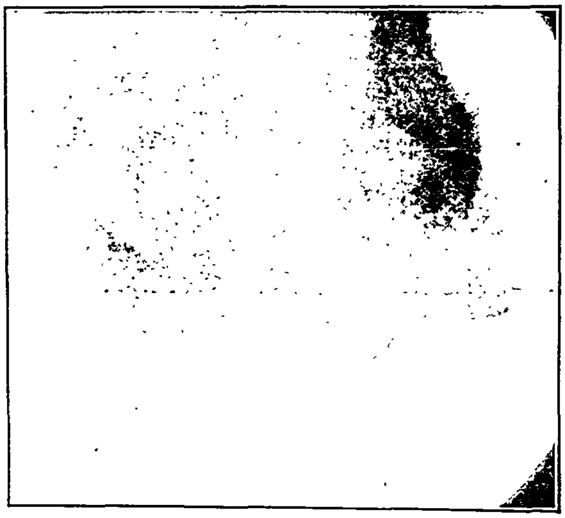

Fig. 3.—Case 9; right Charcot knee.

Examination of the affected parts by roentgenoscopy has been of great value. In the early stages many tabetic joints show little or no deviation from the normal picture. More advanced cases show roughened and fuzzy outlines and often the production of new bone about the affected parts, and some of the advanced cases, bone absorption at points of pressure, and bone atrophy. In several knee and foot cases roentgenoscopy revealed crush fractures when there had been no definite history of injury. Roentgenoscopy also revealed an ossification of the rectus muscle following a spontaneous fracture of the patella, and in several cases detached bits of bone, some of which could be palpated. In one patient with a right Charcot knee and foot, the left foot showed hypertrophy of the calcanear tubercle and apparently an os trigonum. In one of the knee cases roentgenoscopy revealed a large bone-plaque behind the knee not complained of.

In the series of twenty-three cases of Charcot joints here studied, the incidence of the trouble was as given in the following tabulation:

	Right	Left	Total
Hip	2	1	3
Knee	11	6	17
Ankle	1	2	3
Tarsus	3	1	4
Ribs	..	..	1
Spine	..	..	1
			29

This includes those cases with more than one joint affected, one each with both hips; right hip and knee; ribs, right knee, ankle and tarsus, and both tarsi. It will be seen that in this group there are no arm cases, and that the knee cases outnumber all the other joints combined. As nearly as could be ascertained the Charcot joint appeared before any ataxic gait in ten, and after ataxia was noticed in eight; in five the precedence is uncertain. Most of the preataxic patients considered themselves in good health, and noticed nothing wrong until the appearance of the Charcot joint, with or without injury. Several, however, had had spontaneous fractures long before the Charcot joint. There is usually little or no pain connected with either a spontaneous tabetic fracture or a Charcot joint.

DEFORMITY

The Charcot joint is usually a large, loose joint filled with fluid, with the increased play, deformities and displacements due to a stretched capsule and eroded articulation. In some cases the swelling goes beyond the joint up and down the leg. In the three hip cases there was total disappearance of the head, and corresponding upward displacement with elevation of the trochanter, and a flail joint with marked instability. At the knee, if the lesion is of many months' duration, there is usually abnormal lateral motion and hyperextension.

If there was a crush fracture of the internal tuberosity or bone absorption on the inner side of the knee there is an out-knee; if these changes have taken place on the outer side there will be an in-knee. Out-knee was noted five times, in-knee five times, and hyperextension seven times in the seventeen knees. In several cases the tibia was also displaced outward. At the ankle and tarsus there was usually enlargement with a tendency to valgus with or without fluctuation. In one case there was extreme tarsal valgus with great enlargement and involvement of the scaphoid, cuneiforms and base of first metatarsal. The enlargement was hard and without fluctuation (*pied tabétique* of Charcot).

In the spinal case there was a rounded lumbar kyphosis; the third and fourth lumbar vertebrae were involved. In several cases loose pieces of bone could be felt about the knee and seen in the roentgenogram. In one there was ossification of the rectus and a practically stiff knee, and in another motion was limited, owing to previous joint infection.

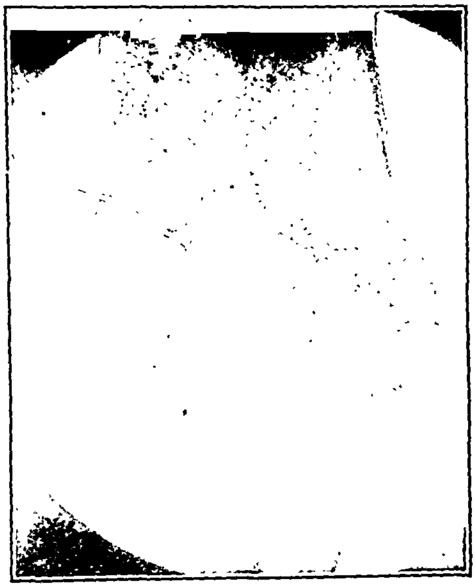

Fig. 4.—Case 10; right Charcot knee after excision.

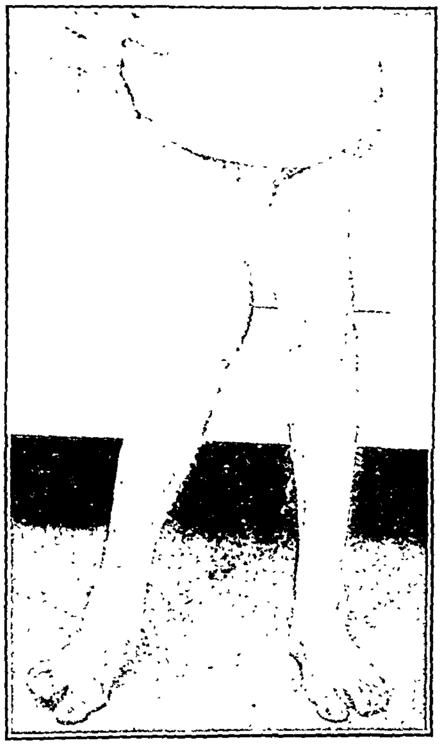

Fig. 5.—Case 13; right Charcot knee.

TREATMENT

Mixed treatment is ineffectual in tabes. Salvarsan several times repeated sometimes gives great relief, especially to the shooting pains and sometimes to other symptoms. One patient in the series had had the knee excised three years before. There was no union, and the patient could not walk without a brace. When the joint changes have not progressed too far, great improvement results from immobilization with a caliper brace (Thomas knee-brace articulating with tube in heel of shoe). The swelling gradually recedes, the joint becomes much firmer, deformity is diminished or corrected, and in a number of instances the patient has gone back to work. In very early cases, before bone destruction, a jointed knee-brace will produce the same result. A jointed brace must also be used when the patient is not able to rise from a chair or balance himself in a stiff brace. In one instance a jointed brace applied elsewhere gave no relief, but when a stiff brace was substituted improvement quickly followed. In early or medium cases, proper orthopedic treatment gives good results.

REPORT OF CASES[3]

Case 1.—*Spontaneous Fracture of Left Femur; Right and Left Charcot Hip; Tabes.*—Man, aged 39, September, 1910.

Case 2.—*Tabes; Right Charcot Knee and Hip.*—Man, aged 48, February, 1910. Has had swollen and weak knee two years. Sudden pain in the right hip two months ago. Not much pain since. Knee reflexes absent; pin-point pupils; hip and knee loose; large swelling with fluctuation. R. A.[3] 29 inches; L. A. 31½ inches; trochanter 1½ inches high. Outer condyle can be felt to be eroded at knee. No pain; marked ataxia. Roentgenogram taken in December, 1909, shows beginning absorption top of femoral head. February roentgenogram shows complete disappearance of femoral head, and crushing down of external tibial tuberosity.

Case 3.—*Spontaneous Fracture Left Femur; Right Charcot Knee (Infected); Tabes.*—Man, aged 29, March, 1911.

Case 4.—*Tabes; Left Charcot Knee.*—Man, aged 49, April, 1913. Severe fall nine years ago; no trouble before. Since then trouble in walking; shooting pains in limbs and back until one year ago. Fell off engine, February, 1912. After that knee swelled, and he has not been able to work. One injection of salvarsan, May, 1912; no improvement. Pin-point pupils, absent knee-jerks, marked ataxia. Has large painless left knee, with in-knee, and loose body near patella. There is hyperextension at both knees. A stiff brace was made for the left knee, and the swelling disappeared in about a month. Roentgenograms showed bone changes about left knee and some loose pieces of bone. The patient is reported to have died the last of May, after a two weeks' illness.

Case 5.—*Tabes; Crush Internal Tibial Tuberosity; Right Charcot Knee.*—Man, aged 36, November, 1912. A fall on the ice in December, 1911, was followed by swelling of knee, which has persisted. Has a moderate out-knee (Fig. 1), but very little pain. Has ataxia, Romberg's sign, absent knee-reflexes and sluggish pupils. Has swelling lateral motion at knee, displacement of tibia outward, and some crepitus; flexion stopped short of a right angle; walks without support. Looks quite thin and miserable, but works as night clerk. Stiff brace (caliper) applied. After several months his knee was much improved. Roentgenogram (Fig. 2) shows irregular bone at sides of joint and a loose piece at inner side.

Case 6.—*Tabes; Right Charcot Knee.*—Man, aged 35, October, 1909. Ataxia in walking six months, swelling of knee a few weeks. Has ataxia; absent knee-jerks, pupillary symptoms, and large loose knee. The roentgenogram showed no great changes. After jointed brace had been worn for lateral support for four months, the swelling entirely disappeared, and the knee seemed to be practically restored to normal.

Case 7.—*Tabes; Left Charcot Knee.*—Woman, aged 44, May, 1912. Has had shooting pains in legs sixteen years or more, and incontinence of urine (dribbling) three or four years. Knee began to swell four months ago; was very large, not very painful; slight ataxia and Romberg's sign were present; knee-jerks absent; pin-point pupils; knee improved after application of a stiff brace. Roentgenogram shows fuzziness, lipping and overgrowth, outer side joint and under patella. Tibia is displaced outward.

Case 8.—*Spontaneous Fracture Left Femur (Twice); Right Charcot Knee; Tabes.*—Man, aged 50, November, 1910.

Case 9.—*Tabes; Right Charcot Knee.*—Man, aged 48, March, 1913. Pains in legs twenty years, and difficulty in walking

---

3. Cases 1, 3, 4, 11, 14 and 22 have already been reported under the title "Spontaneous Fracture as an Initial or Early Symptom of Tabes Dorsalis" in the New York State Journal of Medicine, October, 1912, and the *Post-Graduate*, November, 1912, where full histories may be found.

3. R. A. is the distance from the anterior superior iliac spine to the tip of the internal malleolus on the right side; the same distance on left side.

three years; right knee was swollen three years; now marked ataxia; fixed small pupils; absent knee-jerks; slight Romberg; in-knee, hyperextension, and lateral mobility at knee. Right knee 18½; left knee 15; knee not painful. Has worn jointed brace two years without benefit; knee now improving under stiff brace. Roentgenograms show extensive bone changes about condyles, crush of external tibial condyle and several loose fragments of bone. (Fig. 3.)

CASE 10.—*Tabes; Right Charcot Knee Excision; Non-Union.*—Man, aged 48, November, 1912. States that he injured right knee crawling under locomotive four years ago. After this knee swelled and patient had trouble in walking; knee was not painful. Three years ago knee was excised, but bones did not unite. Since then he has had shooting pains in legs and has worn a stiff brace. Patient now has ataxic gait, Argyll Robertson pupils and absent knee-jerks. Knee may be hyperextended to 190 and flexed to 70. There is little swelling and no fluid. (Fig. 4.)

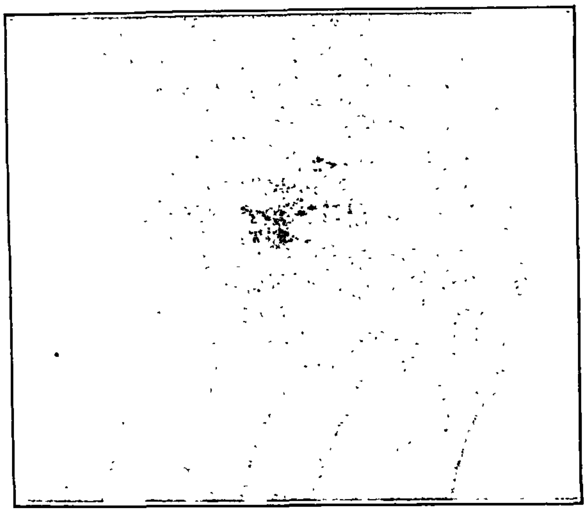

Fig. 6.—Case 21; right and left Charcot tarsus.

CASE 11.—*Spontaneous Fracture Left Internal Tuberosity of Tibia; Tabes.*—Man, aged 42, September, 1910.

CASE 12.—*Spontaneous Fracture Right Patella; Myositis Ossificans of Rectus Cruris; Tabes.*—Man, aged 37, July, 1909.

CASE 13.—*Right Charcot Knee; Tabes.*—Man, aged 38, May, 1908. Incontinence of urine at night for many years. Painless swelling in right knee began two years ago; no trouble with walking till last six months. Now little ataxia; Argyll Robertson pupils; absent knee-jerks; delayed sensation; no shooting pains; in-knee and swelling (Fig. 5).

CASE 14.—*Tabes; Fracture Left Humerus; Spontaneous Fracture Left Tibial Tuberosities.*—Man, aged 46, May, 1912.

CASE 15.—*Tabes; Right Charcot Knee.*—Woman, aged 44, April, 1910. Knee greatly enlarged over a year, painless; ataxia and other tabetic symptoms. Roentgenogram shows crush and displacement of internal tibial tuberosity.

CASE 16.—*Tabes; Right Charcot Knee.*—Man, aged 35, October, 1909. Ataxic gait six months; painless swelling in knee two months; some hyperextension. Has absent knee-jerks, pupillary symptoms and shooting pains. Roentgenogram shows no gross bone changes. Jointed knee-brace, with stop to prevent hyperextension applied. Swelling entirely disappeared in four months.

CASE 17.—*Left Charcot Knee; Tabes.*—Man, aged 34, May, 1912. No injury; no ataxic gait. Knee began to swell seven months ago: slight pain in beginning, none now. Knee-jerks absent; slight Romberg; Argyll Robertson pupils; no ataxia in arms or legs; no lightning pains. Large, loose knee, with effusion.

CASE 18.—*Charcot Ribs; Right Charcot Ankle, Tarsus, and Knee; Tabes. Improvement after three injections of salvarsan.* Man, aged 50, October, 1912. Bladder symptoms (dribbling), girdle pains and shooting pains in legs appeared about ten years ago, also localized swellings on ribs, appearing from time to time and lasting from four to eight weeks. One is present now on right side and one has just gone on left. Right knee began to swell three years ago, and right ankle six years ago. Did not have much trouble with gait until knee began to swell. Girdle pains disappeared six years ago. Fixed pin-point pupils; absent knee-jerks; Romberg and marked ataxia. After three injections of salvarsan two years ago, ulcer which had been present on ball of small toe six years healed in one week and has not recurred; has had no pains in legs or dribbling since; general health and gait improved, and swelling of knee diminished. Weakness in right knee and ankle have progressed and for the last three months has been able to walk only with the aid of crutches. Roentgenoscopy reveals some hyperostosis under patella and back of joint; disintegration at right astragaloscaphoid; also hypertrophy of left calcanear tubercle and left os trigonum.

CASE 19.—*Fracture Above Ankle; Charcot Ankle; Tabes.*—Man, aged 43, February, 1909. Fracture above left ankle nearly three years ago; two years ago ankle began to swell with some pain. Absent knee-jerks; Argyll Robertson pupils; no ataxia; walks well with eyes shut; has cystitis. Much bony enlargement about ankle; moderate pain in walking; good ankle motion.

CASE 20.—*Left Charcot Ankle; Tabes.*—Man, aged 33, March, 1911. Treated four years ago for gastric pains; knee-jerks absent; right pupil fixed and dilated, left sluggish; slight Romberg; moderate ataxia of gait, slight of arms. Left ankle enlarged.

CASE 21.—*Right and Left Charcot Tarsus (Pied Tabétique.)*—Man, aged 57, December, 1912. Both feet in marked tarsal valgus, with much firm enlargement of scaphocuneiform region; no pain; no fluctuation. Typical symptoms of tabes, but ataxia absent (Fig. 6).

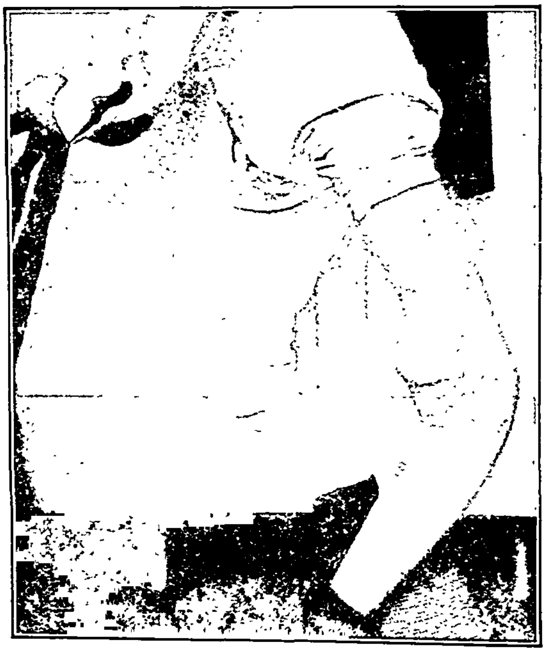

Fig. 7.—Left Charcot knee extreme hyperextension; no history.

CASE 22.—*Spontaneous Fracture of Right Astragalus; Charcot Astragaloscaphoid Joint; Tabes.*—Man, aged 30, February, 1912.

CASE 23.—*Charcot Spine; Tabes.*—Man, aged 47, March, 1913. Fell 6 feet, May, 1910. Next day was unable to walk, but could walk with difficulty five days later. Pain in lower back and about left thigh since. Has had many kinds of treatment since, but has grown steadily worse. Now walks and stands with difficulty; marked kyphosis in lumbar region; no ataxia; no Romberg: sluggish left [illegible] right [illegible] jerk absent, left present; antilue [illegible]

Wassermann negative. As the patient was growing steadily worse, a bone grafting was advised, and a transplant from the tibia was implanted into the three lower lumbar vertebrae and sacrum. The patient grew steadily worse and died six days later. Roentenogram showed left half of body of third lumbar and right half of fourth nearly destroyed; considerable displacement of third vertebrae to right.

CONCLUSIONS

One seems warranted in concluding from this series of cases that:

1. Charcot joints and spontaneous fractures are often initial or early symptoms of tabes dorsalis.
2. They often precede the ataxic gait, and are of diagnostic importance in calling attention to the underlying tabes.
3. Charcot joints are frequently of traumatic origin and often follow fractures, and lesser injuries.
4. The results of orthopedic treatment in early or moderately advanced cases of Charcot joint are extremely satisfactory.
5. Orthopedic treatment by protective splinting should also be used in the loose joints of tabes due to hypotonus before the appearance of swelling and effusion.
6. As ataxia is frequently one of the later symptoms to appear, the term "locomotor ataxia" to designate the affection is misleading and should be discarded. "Tabes dorsalis" should be used in its stead.

I wish to thank my colleagues at the Post-Graduate Hospital and the Hospital for the Ruptured and Crippled for their kindness in referring cases and valuable aid in their study.

128 West Fifty-Eighth Street.

ABSTRACT OF DISCUSSION

Dr. J. D. Griffith, Kansas City, Mo.: I had a case of Charcot's disease of the hip-joint in which there was complete absorption of the neck itself. The patient was a Chinaman, 67 years old, with a decidedly luetic history. He had never had a bad symptom or any great difficulty in getting around until he had an accident in May, 1913. He was walking with a cane and suddenly found, without any premonitory symptoms, that the leg gave way in stepping down the stairs. The patient had no pain, but the leg was greatly swollen and edematous. The roentgenogram showed that the head of the femur was practically destroyed, only a small piece being left in the acetabulum. When the man came to the hospital, there was an effusion about the joint, as well as quite a formation of new tissue, with a shortening of the leg of about 2 inches. One peculiarity about the case was that there was no loss in the power of lifting the leg and placing it in different positions, and the ordinary tests for fracture were negative. There was nothing to indicate that there was a complete absorption of the neck of the femur. We kept him in bed for a few days and had an ordinary Thomas hip-splint made for him—one with a fixed shoe; we adjusted that after he had recovered sufficiently. He is walking around on crutches now.

A second case is that of a man who is stout, strong and able-bodied, with a negative history. He had had no trouble, except that he was noticeably commencing to walk with one hip rather prominent, and was going slightly sideways. He weighed over 150 pounds. He had no pain, but thought that he had hip-joint trouble. The roentgenogram showed nothing the matter with the joint, but a little trouble higher up in the spine. There was no evidence of pain on examination and not a single spinal symptom. He gave no history of lues.

Dr. F. J. Cotton, Boston: I should like to agree with all that Dr. Taylor has said. I see a great many of these cases under different circumstances in a general surgical clinic, and they are usually those that my colleagues let go by. They are not the bad instances of Charcot joints, and have previously been treated with more or less Christian Science methods. They are unrecognized cases. I am familiar with the kind of cases that Dr. Taylor mentioned, but I should like to mention the subclass—cases that are generally unrecognized. They are types of low tabes. You do not get the Argyll Robertson pupil in them, but slightly sluggish light-reflexes and absent knee-jerks occur almost always. It is these "low" cases in which we often have for many years serious bladder trouble without any ataxia and without any development of other symptoms. All the cases of this kind that I have seen have existed for many years; not one has been ataxic or shown a clean-cut picture of tabes dorsalis. The patients come in for unexplained joint injuries that are supposed to be traumatic. They are sometimes recognized after the failure of some method of treatment.

You really have a clean-cut picture. There is a painless joint, more or less thickened, without effusion, with no joint spasm, with abnormal mobility. Sometimes there is the lancinating pain of tabes; sometimes this is absent.

Sometimes there is an appearance of erosion of the cartilage, a smudged picture of the bone outlines and a characteristic exhibition of formless bony matter in the articular capsule.

If you cut into these joints, you find a pathologic picture of a thickened capsule with bone-plaques scattered around. All Dr. Taylor's cases, except the one in which osteotomy was done, showed this type. I have felt no hesitation in making the diagnosis, and then sending the patients to the neurologist for confirmation. Sometimes the nerve specialists said that there was no tabes; but when I insisted that there was, they finally made the diagnosis. These conditions occur more frequently in women than in men, and with no definite syphilitic history; but, as we believe, with syphilis lying back of it.

The cases are important because the orthopedic surgeon can do something good by means of apparatus, although other things do not do the slightest good. The patients often come to the hospital for operation.

Dr. Gilbert Bailey, Oak Park, Ill.: I wish to emphasize the painless character of many of these joints. I recall the case of a man, a carpenter, who was admitted to the Cook County Hospital. He had been doing some work on a door and, while attempting to drive a nail through the door, drove it into his shin. It took the force of two men to pull him away. Before the accident he had considered himself perfectly well. Three months later he began to notice a swelling at the site of the injury and he sustained a spontaneous fracture. Several months later a Charcot joint developed at the ankle. The fact that the Charcot joint developed without the usual tabetic pains, and after the trophic disturbance seemed interesting.

Dr. John Ridlon, Chicago: I have seen three cases in which the first diagnosis of tabes was the joint condition as shown by the roentgenogram. Its existence was not suspected until then. Therefore, in all obscure joint cases in which the diagnosis is not clear, a tabetic joint must be seriously considered. Another point that must be remembered is that tabetic joints must not be operated on. The patient is positively harmed by operation.

Dr. Henry Ling Taylor, New York: This discussion emphasizes some points that I should have emphasized more in my paper. My experience agrees with that of Dr. Cotton; nearly all these cases are diagnosed for the first time in an orthopedic clinic or in the private office of an orthopedic surgeon. This series of cases also includes a great many cases of tabes in which some of the classical symptoms are absent. I refer all doubtful cases to a neurologist for detailed study.

Legal Decisions in Medical and Surgical Cases.—There are some things which it is not wisdom to attempt, and an explanation of the way in which decisions are arrived at in courts of justice where medical and surgical matters are concerned is one of them.—C. Mansell Moullin, in (London) *Clinical Journal.*

THE RECOGNITION OF EARLY CHANGES IN THE LARYNX IN TUBERCULOSIS *

W. E. CASSELBERRY, M.D.
Professor-Emeritus of Laryngology and Rhinology in Northwestern University Medical School; Laryngologist to St. Luke's Hospital
CHICAGO

Not differing from tuberculosis elsewhere, the first definite change provoked by the bacillus in the larynx is an infiltration of the mucosa and submucosa by a diffusion of small, round, mononuclear cells, interspersed among which are collections of epithelioid and lymphoid cells in the form of tubercles, which are deposited, in large part, in the connective tissue beneath the epithelial and structureless layers, and hence near enough to the surface to change its aspect in form and feature. Accordingly, the recognition of early changes in tuberculosis of the larynx will be promoted by keeping in mind:

First, the disposition of tubercles and tuberculous nodules to assume a globular form, which gives the surface of the infiltration, also termed hyperplasia, a mammillated aspect.

Secondly, their disposition to excite verrucous and granulomatous formations which, though ordinarily delayed till the stage of ulceration, may make an earlier appearance and give the surface a papillomatous aspect.

Thirdly, their disposition to excite serous exudation which may give the surface, not the proportions of gross edema familiar at a later stage as "turban-shaped" and "pyriform," but an aspect of incipient edema which, by a touch of pallid color and somewhat tense consistency, imparts just the "atmosphere" necessary to lend distinction to the composition.

Moreover, although by no means exclusive, tuberculosis favors certain sites in the larynx, each of which tends to stamp the lesion, whether mammillated hyperplasia, verrucous formation or incipient edema, with its own local functional or anatomical mark and, though the stamp be that of location rather than of lesion, its impress on a tuberculous matrix is apt to leave a mark distinctive of the lesion itself. Especially is this true at a site which, lacking a definite name, is herein designated, together with a description of its location and function, as the vocal angle (Fig. 1).

Though a feature of the larynx, the vocal angle is not a separate anatomical part, but a line of junction of several parts, the terminals of which converge at an angle. In length, the angle starts at the base of the vocal process as represented by a small three-cornered area beneath the terminal ridge of the cord, and, mounting with a posterolateral trend, it marks the line at which the superficial structures of the true cord, the false cord and the interarytenoid fold merge into one. The function of the vocal angle is somewhat like that of a hinge, its overlying mucosa folding in and out with every movement to and fro of the vocal cord in speaking, and, though under normal conditions it withstands unharmed this perpetual creasing, a tuberculous infiltration will cause it to retain, in the form of a furrow or fissure, the impress made on it at the folding line.

The mammillated hyperplasia fundamental to the furrow is prone to make its first appearance and the furrow to take its start at the lower extremity of the vocal angle in or near the small three-cornered whitish surface of the base of the vocal process. Although this is a point of greatest significance in the early recognition of tuberculous changes in the larynx, it is doubtless often overlooked because it lies beneath the ridge of the cord near its terminus and does not flash into full view in the mirror until the moment of deep inspiration with widely separated cords which naturally follows a prolonged vowel sound. In the half-opened position of the cords, during ordinary breathing, it is only partly visible, and in the closed position not at all visible. The infiltration, however, is rarely limited to this one spot and may make its first appearance anywhere along the vocal angle. Also, instead of at the base, it may first be perceived clustered around the apex of the vocal process, that salient point in the edge of the cord often erroneously referred to as if it were the whole vocal process, although in fact only its apex. The furrow, in the beginning, is simply the folding line or corner of the angle, given depth by thickening of its borders; but, as the infiltration augments, especially near the terminus of the false cord, the furrow becomes more pronounced and sooner or later it becomes a fissure, perhaps exciting granulomatous formation as it cuts into the rim of the larynx at the arytenoid.

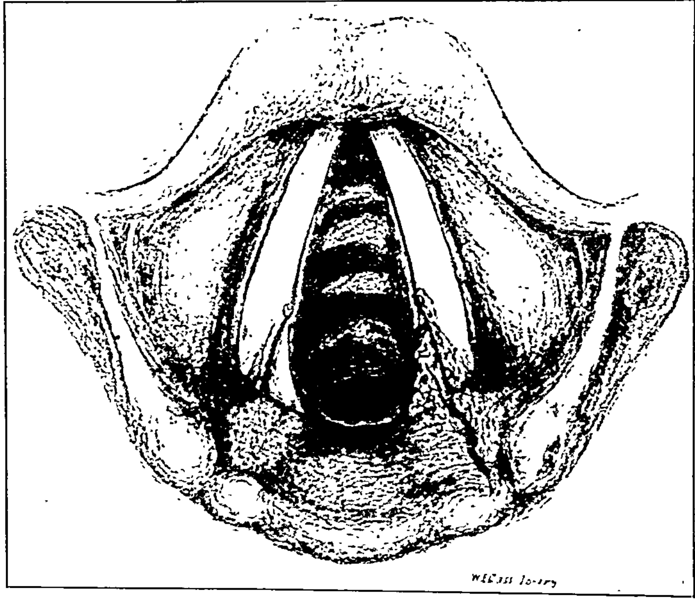

Fig. 1.—Mammillated tuberculous hyperplasia with a furrow at the vocal angle, which is one of the earliest and most distinctive of the initial lesions.

I consider, therefore, that hyperplasia of a mammillated or other typical aspect commencing at or near the subglottic portion of the base of the vocal process, and marked gradually by a furrow in the vocal angle, is not only one of the earliest, but also the most distinctive of all the initial changes wrought by tuberculosis in the larynx (Fig. 2). So soon may it appear that, in a semiquiescent state, either alone or following interarytenoid hyperplasia, it may precede by months or years any more active developments; for it is now realized that, like its parent lesion in the lung, a tuberculous infiltration in the larynx may remain indefinitely in what is the equivalent of an early stage of development, perhaps in the end to flare up or perhaps, as I have elsewhere shown,[1] to recede, in the proportion, considering all types, of 20 per cent. So distinctive is it that, by way of comparison, it may be said to indicate tuberculosis at a period before interarytenoid hyper-

---

* Read before the American Climatological Association at the Congress of American Physicians and Surgeons, May 8, 1913.

[1] Casselberry, W. E.: The Journal A. M. A., Aug. 7, 1909, p. 436.

plasia, if alone, will have passed the stage of similarity to non-tuberculous infiltrations. Even the broad-based, centrally cleft interarytenoid hyperplasia, long regarded as characteristic of tuberculosis, before reaching its typical development, must pass through indistinguishable stages; for simple inflammatory hyperplasia having a crinkled, rugous and moderately elevated aspect, indistinguishable when limited to the interarytenoid fold from the early tuberculous type, is not uncommon especially in connection with nasal accessory-sinus suppuration, retention tonsillitis, asthmatic bronchitis, tobacco pharyngitis, etc., and pulmonary patients, no less than others, are liable to these affections. Therefore, not even in the presence of pulmonary turberculosis itself will a moderate degree of interarytenoid hyperplasia, unsupported by infiltration at any other site, advance the diagnosis beyond the question whether it is tuberculous laryngitis or simple laryngitis in a tuberculous subject, excepting that any persistent hyperplasia in the larynx which supervenes in rapidly progressive pulmonary tuberculosis of the non-resistant type obviously requires no additional confirmation of its tuberculous nature.

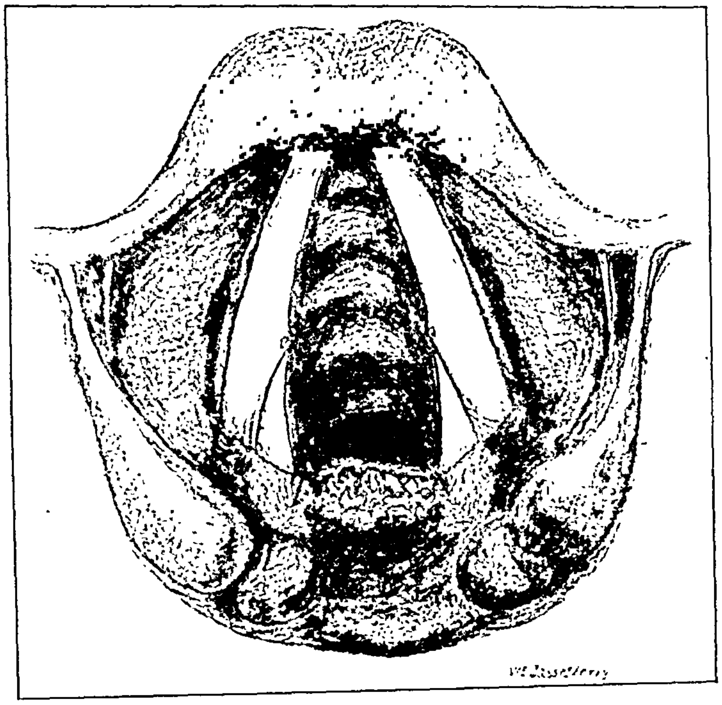

Fig. 2.—Interarytenoid hyperplasia which, existing alone, is of little diagnostic significance at an early stage as it is commonly simulated by non-tuberculous hyperplasia in the same situation.

It follows that, in the problem of distinguishing between tuberculous laryngitis and simple laryngitis in a tuberculous subject, most of the cases concerned are of hopefully resistant type, usually evidenced, despite a definite deposit in the lungs, by a fair state of nutrition, moderate pulse-rate and but few bacilli, the interarytenoid hyperplasia in question being of moderate and slow development. St. Clair Thompson refers to this type of case as lupoid tuberculosis, but it is quite different, eventually running the course of laryngopulmonary tuberculosis and not that of lupus. The prognosis, however, is hopeful and the actual results justify every effort at any sacrifice to invoke the methods most likely to secure its arrest; so that any loss of opportunity through lack of early recognition of that which later on is liable to become the major life-threatening factor in the case does an irreparable injustice to the sufferer. At the same time, any pronouncement of tuberculous laryngitis, based in error on a non-tuberculous interarytenoid hyperplasia, is liable to work a corresponding injustice to him who, though a tuberculous subject, has but a simple chronic laryngitis; for the sacrifice of life's ambitions and business interests likely to be involved in the treatment and mode of life under the idea of laryngeal tuberculosis is far greater than in pulmonary tuberculosis alone. As a single instance, the item of rest may be mentioned, which should include not only rest for body and mind, but also rest for the voice and rest from the exactions of business. If, however, an infiltration at the vocal process with a furrow in the vocal angle be recognized in addition to the questionable interarytenoid hyperplasia, the problem is then safely solved, the answer being laryngopulmonary tuberculosis (Fig. 3).

It is somewhat later that the sign at the vocal angle reaches its most characteristic bilateral development, when, together with interarytenoid hyperplasia, it gives to the semicircular form of the posterior commissure a square or box-like effect, a veritable "squaring" of the semicircle. It forms a striking picture (Fig. 4) believed to be sufficiently characteristic of tuberculosis of the larynx to justify a tentative diagnosis even in the supposed absence of pulmonary disease which, on thorough search, will then be brought to light. That the prognosis still is hopeful is illustrated, first, in Figure 4, drawn in 1901 from the case of J. W. D. in which the mammillated hyperplasia of the interarytenoid fold and of both vocal angles with a furrow at the right and a fissure at the left and with granulomas forming about the fissure were absolutely characteristic of tuberculosis; and next, in Figure 5, drawn seven years afterward from the same case, which shows that full recovery has ensued with respect to the larynx, a smooth scar, the result, in part, of intralaryngeal surgical treatment, being the only reminder of its former condition.

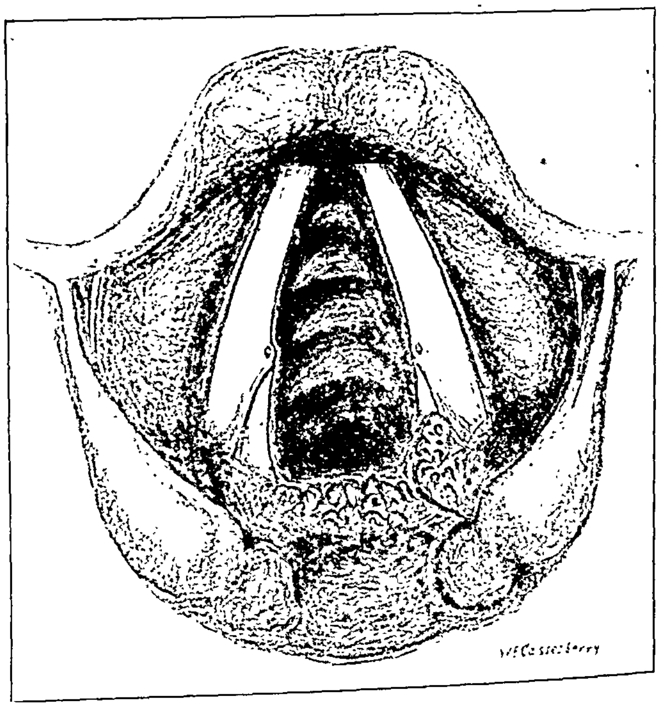

Fig. 3.—Interarytenoid tuberculous hyperplasia which is given diagnostic significance by the accompanying hyperplasia and furrow at the vocal angle.

It is not to be inferred that the sign at the vocal angle has heretofore escaped observation, for, although no mention is made of a furrow or fissure, it is discernible in various illustrations, including Nos. 3, 9 and 12 in the series of realistic sketches by C. L. Minor,[2] who also describes as "very suggestive the early appearance of thickening at the posterior insertion of the cord and a small white triangular ulcer" which he locates at evidently the same spot herein described as a three-cornered surface at the lower extremity of the vocal angle beneath the terminus of the cordal ridge.

The initial lesions at other sites, although not of frequent occurrence individually, are too numerous in the aggregate, to permit of more than passing notice limited to those which may serve incidentally to accentuate the "motif" running through the theme; so that the diagnosis of the earliest definite infiltration will be promoted, while the pathologic trend is kept in mind, by an ability to recognize it—whether mammillated hyperplasia, verrucous formation or incipient edema—in the guise of the varying stamp placed on it at different local sites. Take, for instance, lesions in the fibrous portion of the vocal cord whose firm tissue-bundles by affording an extra lateral resistance encourage the "fusiform" style of development most characteristic of hyperplasia of the cord; the fusiform, then, if abbreviated and in multiple, becomes an "undulating or wave-like" infiltration of the cord; if it is elongated and in duplicate, it constitutes a type of "double cord." Again, verrucous formations and nodules in pairs, like simple warts and singers' nodes, seem to be led into these forms of development by vocal attrition of the cords.

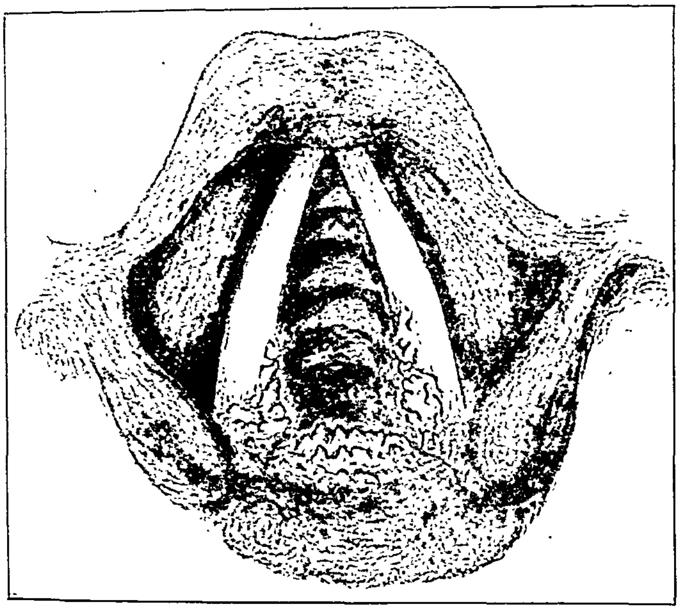

Fig. 4.—"Squaring of the semicircle" in the Case of J. W. D. The mammillated hyperplasia of the interarytenoid fold and both vocal angles with a fissure and granulomas at the right and a furrow at the left present an aspect absolutely characteristic of tuberculosis of the larynx. Recovery, however, ensued as seen in Figure 5.

The epiglottis, although rarely the first feature to manifest infection, provides the most favorable condition for exhibition to the naked eye of individual tubercles which, of course, represent, in diminutive, the elements of mammillated hyperplasia. Half of the epiglottis, in a case now in mind, was marked by many grayish-yellow, pin-point, slightly raised granules scattered beneath a translucent, somewhat edematous surface. I should not omit to mention, in connection with the mention of this unpromising initial condition, that the patient made an excellent recovery with respect to the larynx and experienced a practical arrest of the condition with respect to the lungs, and now, fourteen years afterward, is in an efficient state of health.

The arytenoid in exceptional cases may provide the first indication of a laryngeal complication by suddenly becoming edematous. This condition, when pronounced, is an evil omen indicative of the non-resistant type of the disease and characterized with respect to the laryngeal involvement by speedy development, persistent progress and rapidly fatal termination. This is the type previously mentioned as obviously requiring no additional confirmation of the tuberculous nature of any infiltration which might occur in the larynx. Having stated in connection with its opposite, the hopeful variety, that the results of treatment justify any sacrifice, it is incumbent now to state that this non-resistant type should be carefully differentiated, no serious sacrifice being justified by the results of treatment; instead, these patients should be guarded from the privation and distress which surely follow in the wake of an indiscriminate exposure to the elements and to the hardships of travel in distant climes. Any attempt, likewise, at local surgery is but to court opprobrium and invite disaster, whereas, in the hopefully resistant type, with lesions not too diffused and reasonably accessible, intralaryngeal surgical measures have proved helpful in mitigating suffering, prolonging life and promoting arrest.

Can a diagnosis then always be made from the laryngeal image alone? No, not always; for the infiltration may not have developed sufficiently, and it cannot be said that even a furrow at the vocal angle may not in rare instance be simulated by the hyperplasia of syphilis, pachydermia, etc., so that every additional test must be applied in order to remove doubt or to make assurance doubly sure. Even then it must rest on the laryngeal image to disclose that accentuation of the infiltration which constitutes a positive local reaction from a systemic tuberculin test which, following the exclusion of syphilis by the Wassermann test, should dispel any remaining doubt.

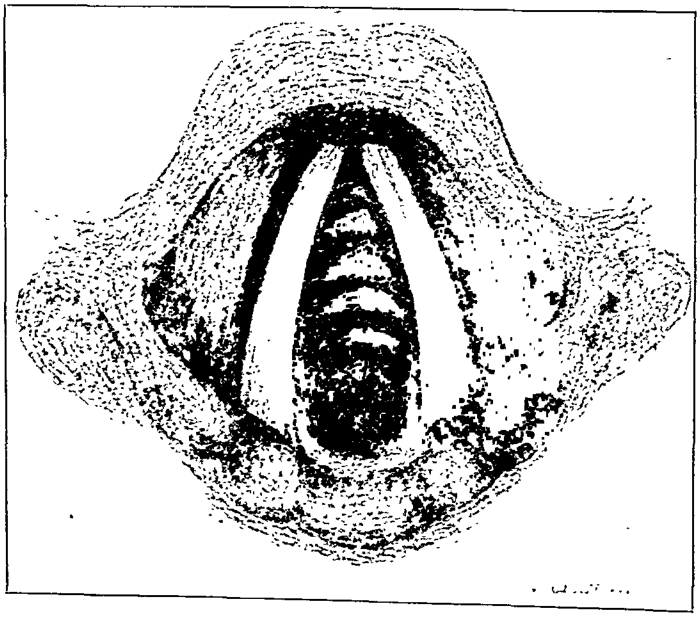

Fig. 5.—Case of J. W. D., seven years afterward, showing the larynx fully recovered from tuberculosis, with only a smooth scar the result of treatment, in part, by surgical measures.

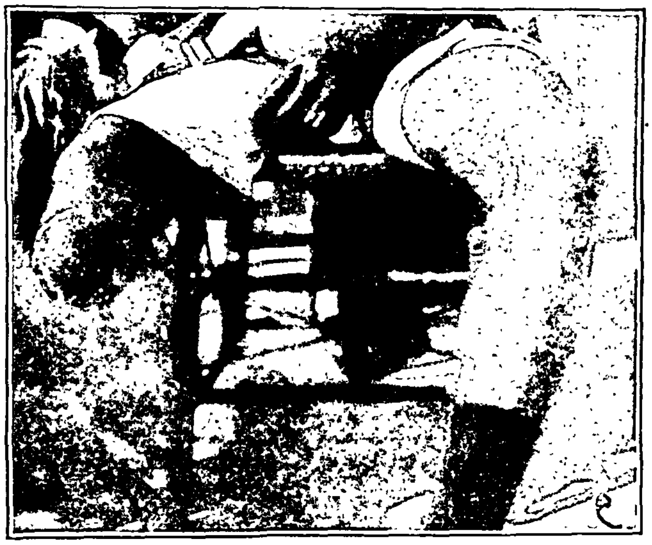
AUTOPLASTIC OPERATIONS TO COVER STUMP SUBSEQUENT TO AMPUTATION OF LEG OR THIGH

C. E. PHILLIPS, A.B., M.D.
Chief of Surgical Clinic, Colon Hospital
CRISTOBAL, C. Z.

Probably every surgeon who has done much accident work has occasionally sacrificed a useful leg stump, a knee or vital length of thigh—vital as far as function goes—because of insufficient tissue available for flaps, or has had to reamputate a leg or thigh to secure a proper covering for the bone, and, by the additional shortening, has seriously impaired the subsequent usefulness of the stump.

By bearing in mind always the fact that in the opposite leg or thigh we have a surplus of tissue which may be borrowed in case of need to fill almost any deficiency, we shall be following a policy of conservation of human tissue which will minimize the disabilities arising from accident or disease affecting the lower extremities.

For instance, in traumatic amputation in the upper third of the leg where, in order to perform a satisfactory amputation, the knee-joint must be sacrificed, we shall simply clean and trim off the lacerated tissue and as much of the bone as can be spared without interfering with function, dress the wound and allow it to granulate. When the end presents a clean granulating appearance, we borrow enough tissue from the opposite thigh or leg to supply the defect, and the patient retains a functionating knee-joint and all the benefits to be derived from it in wearing an artificial leg.



Transplant in Case 1, and area on the left thigh from which it was taken.

The same procedure may be followed in amputations of the thigh when in traumatic cases we are able to preserve a functional length of stump by trimming off the lacerated tissue, sawing the bone off flush with the end of the stump, and, at a later date, borrowing a mass of tissue from the opposite thigh to cover the end of the stump.

Likewise in cases in which a reamputation would usually be performed for tender or thinly-covered bone, the tender or attenuated skin may be cut away and the defect covered by means of a flap from the opposite thigh, preserving the entire length of stump and relieving the condition.

So also in severe septic cases requiring amputation, to keep in mind the possibility of supplying subsequently soft parts to fill in defects makes us refrain from cutting off much that heretofore has appeared valueless.

From whatever cause the condition may arise, the indications for the operation appear not infrequently.

TECHNIC

1. The area to be covered should present a clean, granulating surface—all crusts, thickened loose areas of skin should be removed and the whole area well coated with iodin. Then, with a sharp knife, the denuded area should be excised, cutting through the normal skin all the way round and removing a sufficient amount over the granulating area to insure a level cut surface. The skin margin is freed and elevated all the way round. The end is packed temporarily with gauze out of hot saline solution to check hemorrhage.

2. A flap is cut on the opposite leg or thigh, including skin, fascia and muscular tissue, with an attachment containing sufficient blood-supply to insure its viability until such time as it establishes circulation through the prepared area.

3. By this time if oozing has ceased on the stump, the flap should be brought over the end of the stump and sutured to three sides of the skin margin, care being taken that there is good apposition without tension.

The legs are then firmly fixed together so that there can be no movement to disturb the flap, first by means of silkworm-gut sutures and, secondly, by adhesive strips applied some distance from the site of the operation. The limbs are put up in a voluminous dressing for about sixteen days, when it is usually safe to sever the flap from the parent leg or thigh, and complete the operation by suturing the cut edge to the remaining skin margin on the stump. The area from which the flap has been taken is skin grafted.

Two characteristic cases are reported, one a leg and the other a thigh amputation, performed nearly five years ago while I was in Ancon Hospital.

Case 1.—West Indian negro, aged 36, suffering from typhoid fever, was struck by a train, July 2, 1908, and was brought to Ancon Hospital with a compound depressed skull fracture and traumatic amputation of right leg at junction of middle and upper thirds. The depressed fragments of skull were removed and the leg hastily amputated in upper third. The flaps were short and included lacerated tissue. After several days the attempt proved unsuccessful, the flaps parted and allowed the end of the tibia to protrude. The end of the stump was dressed until it presented a clean, granulating surface about 3 by 4 inches.

To shorten the bone sufficiently to allow the flap to meet without tension would have necessitated a sacrifice of leg stump and all it means in the wearing of an artificial leg.

Sept. 9, 1908, the patient was again anesthetized, the granulating end of the stump freshened, and the skin edges freed. Then a flap was laid down beginning on the inner side of the left thigh at about the junction of the middle and lower thirds, including skin, fascia and a small amount of muscular tissue, and extending to the level of the knee-joint. The flap, before it was cut, was about 5½ inches square. The attachment was nearly over the knee-joint.

The legs were placed together and the flap brought around the end of the stump and sutured to the skin margin along three sides, the fourth or internal side of the flap corresponding to the base of the flap. The base of the flap being higher than the denuded area, a good apposition was secured over the entire end of the stump. The legs and thighs were firmly fixed together by means of sutures and adhesive strips for a period of sixteen days, when the patient was again etherized and the flap severed from the parent leg, approximated and sutured to the remaining skin edge of the stump. The denuded area was skin grafted.

The result was all that could be hoped for. The bone was sufficiently covered by a tough, insensitive fleshy pad, which, by contraction, had markedly lessened the area of the transplant and thickened it to 2 or 3 cm. It has successfully withstood the wear and tear of an artificial leg for nearly five years.

Lately, the artificial leg has become so loose that the patient stuffed the lower part with rags, paper, etc., and allowed the end of the stump, that is, the autoplastic pad, to take the entire body-weight. This caused a slight abrasion which promptly healed when the irritation was stopped.

Case 2.—Traumatic amputation through mid-thigh, a patient almost in a moribund condition from shock and hemorrhage. Almost no operative measures except cleaning and trimming of lacerations could be performed on account of the patient's condition. The patient rallied and the stump was dressed until the end presented a clean, granulating surface of about 5 inches in diameter. He was anesthetized and a thick flap of skin, fascia and small amount of muscular tissue were cut from the opposite thigh, beginning nearly in the gluteal fold and extending down the antero-internal and postero-internal sides for a distance of about 6 inches, and having about the same width. The base was about midthigh. After freshening of the granulating surface and freeing of the skin margins on the stump, the flap was drawn around the end of the stump and the edges sutured to the skin margin on three sides. The thighs were firmly fixed together by means of sutures, adhesive strips and bandages. As there was more or less oozing from such an extended, denuded surface, the wound was dressed at the end of one week. On the sixteenth day the flap was severed from the parent thigh and approximated to the remaining skin margin on the stump. This furnished the patient with an ideal stump, well-covered with tissue, not painful and still retaining sufficient length to move an artificial leg.

The operation is indicated in those cases in which the requisite shortening to procure a good stump will interfere with its usefulness, and the patient's general condition is such that he can stand the operation plus about three weeks in bed. There is some pain associated with the fixed position the patients are forced to take, but this is not very severe.

The operation is contra-indicated in those cases in which a reamputation does not seriously interfere with the usefulness of the limb, because it subjects the patient to an added operation or two and prolongs the stay in bed by a considerable time with the attending dangers.

THE SIGNIFICANCE OF GASTRIC ULCER WITH RESPECT TO GASTRIC CANCER

A STUDY OF FIVE HUNDRED AND SIXTY-SIX CONSECUTIVE OPERATIVELY AND PATHOLOGICALLY DEMONSTRATED CASES OF CANCER OF THE STOMACH [*]

FRANK SMITHIES, M.D.
CHICAGO

During the past decade there has been a growing conviction among clinical and laboratory workers that there exists an increasing number of cases clinically admitting a diagnosis only of chronic gastric ulcer which do not pursue an orthodox course of chronicity, but often rapidly assume aspects of malignant disease. If such cases come to laparotomy or necropsy, the surgeon or pathologist demonstrates cancer.

Conversely, surgically and pathologically proved cases of gastric cancer frequently reveal an early clinical history, which at any stage prior to the terminal period of evident malignancy might logically be interpreted clinically as chronic gastric ulcer.

The subject has etiologic, diagnostic and prognostic aspects. Inasmuch as this group of cases satisfies the diagnostic requirements for gastric ulcer and this process of whatever nature it may be later assumes characteristics that we associate with malignancy, and as we have no known medical cure for gastric neoplasms, it would appear imperative to determine how frequently this type of affection exists, in what manner, if any, it manifests itself, the possibilities of its recognition and the indicated treatment when demonstrated. This study has been made in an endeavor to secure information in these directions.

An analysis has been made of 566 operatively and pathologically demonstrated cases of gastric cancer from the Mayo Clinic.

CLINICAL CONSIDERATION

Significance of History: Sex.—In the 566 cases, there were 436 males and 130 females, or 3.1 males to each female. It will be recalled that this is almost the identical sex ratio existing in non-malignant chronic gastric ulcer.[1]

Age.—The youngest patient in the series was 20 years of age; there were twenty-six patients aged over 70. More than three-fourths of the cases came between the ages of 40 and 70 years. A comparative study of 134 cases of non-malignant chronic gastric ulcers shows that rather more than one-half were in the 40 to 70-year period.

Etiologic Factors.—A history of trauma was obtained in 3.4 per cent. of the cases. In 2.9 per cent. the traumatism occurred in the early history of the affection, and it was noted frequently to cause or precipitate symptoms. There were three instances in which husband and wife became affected with cancer within a few months of each other. A family or blood-relationship history was obtainable in 9.2 per cent., and a history of tuberculosis in 1.2 per cent.

Previous Disorders of Digestion (The "Precancerous" History).—More than ten years ago Graham[2] called attention to the significance of the early clinical history in patients presenting themselves in his service for evident gastric cancer. He stated that more than 47 per cent. of his operatively demonstrated cases of cancer had had previous histories which strongly suggested that the cancer had followed a chronic gastric ulcer, existing variously from three to thirty-seven years. Graham also emphasized the fact that nearly 40 per cent. of his cases of cancer were not associated with the previous so-called "ulcer history," but that in this group of cases cancer developed in stomachs which previously functionated normally.

The value of early history as indicating that succeeding cancer of the stomach has its origin in such hypothetic ulcer has been justly questioned. The weakness of the argument appears to be at least threefold: (1) the clinical variation in an ulcer symptom-complex, (2) the indefinite ideas existing as to the time element in the development of "chronic" ulcer and of cancer, and (3) the difficulties in actually proving whether or not a process which is later shown to be malignant was ever anything else. I shall consider these points seriatim.

---

[*] From the Division of Gastro-Enterology, Mayo Clinic.

1. Smithies: Am. Jour. Med. Sc., March, 1913, p. 340.
2. Graham: Collected Papers by the Staff of St. Mary's Hospital, i, 111.

1. To admit the indefiniteness of an ulcer symptom-complex is to grant at once that mistakes in diagnosis are readily possible. That this is a fact has come within the experience of all gastrologists who have handled either a few or a large number of cases. In spite of personal opinions, we must admit that the only gastric ulcers that we can positively say exist are those which we can see or feel. While it may be clinically safer to treat a given case as gastric ulcer, as recommended by Shutz,[3] nevertheless such uncertain procedures have undoubtedly led to error, confusion and irreparable injury to patients. The prognostic aspect of the case is of greater import than the question of type of treatment based on uncertain diagnosis.

In endeavoring to gauge the importance of the previous (the precancerous) gastric history of the cases in our series we found it necessary to group them according to accepted clinical symptom-complexes, of ulcer and of cancer, respectively. This mode of procedure has many faults, but it should be emphasized that this method of classification furnishes the bulk of the literature on the subject.

The clinical symptom-complex considered for gastric ulcer is based on Friedenwald's[4] recently analyzed 409 cases, while that for cancer is compiled from the work of Osler and McCrae.[5] If the value of such grouping is questioned, then the value of much that makes up accepted knowledge of the diagnosis and the treatment of the two ailments must also be questioned. If the symptom-complexes indicated mean clinically ulcer or cancer of the stomach, then the facts that we have to present are not without significance.

We have taken the following symptom-complex to mean gastric ulcer clinically: a form of gastric malfunction occurring usually between the ages of 10 and 70 years, characterized by periodic or continuous abdominal discomfort or pain, frequently bearing definite relation to food ingestion, and often associated with epigastric or dorsal tenderness, vomiting, loss of blood (hematemesis or melena) and with hyperacid gastric contents.

We have considered as "primary" cancer, clinically, a form of gastric malfunction of a downwardly progressive nature, usually occurring in persons between the ages of 40 and 70 years, who have been previously normal gastrically, the imperfect function being characterized by abdominal distress or pain, usually associated with cachexia, loss of blood, epigastric tumor, vomiting and with gastric contents revealing motor defects, low free hydrochloric acid and the presence of organic acids and of foreign micro-organisms.

In grouping our material under these accepted clinical symptom-complexes we find that of the 566 proved cases of gastric cancer, 239, or 41.8 per cent. fall into the cancer-following-ulcer classification, while 182, or 32.1 per cent., are in the "primary" cancer division. There is, in addition, a group which may be termed cases of "irregular ulcer" that numbers 106, of 18.7 per cent. Twenty-two patients, 3.9 per cent., had a previous clinical history of gall-bladder affection, while seventeen, or 3 per cent., had early symptoms pointing to primary processes in the appendix, the pancreas or the bowel. Combining the returns from the two ulcer groups, it is seen that precancerous history indicates that 60.5 per cent. of the subsequently demonstrated cases of cancer gave earlier clinical evidences which we associate with chronic gastric ulcer, prior to the time when the ailment assumed the clinical picture that we associate with gastric malignancy. In but 32.1 per cent. was the disease, from its inception, continuous and progressively downward, and that was in persons who had been previously sound gastrically. These figures are not to be taken as they stand to indicate that nearly two-thirds of all chronic gastric ulcers later become malignant, because we know that ulcers frequently heal spontaneously or continue as chronic, inflammatory processes. Added significance, however, is given to the figures by the observation of the surgical pathologist that more than two-thirds of all excised chronic calloused gastric ulcers show early evidences of malignant metamorphosis (Wilson and MacCarty[6] and MacCarty.[7])

2. The analysis of any considerable material, ulcer or cancer, reveals many striking variations in the duration of the morbid process. Both clinical and pathologic differentiation should be made between the terms old and chronic as applied to ulcer and cancer. Chronicity, pathologically, does not necessarily mean that the disease is old, that is, of long duration in terms of months or years. Large, excavated, calloused ulcers may apparently develop in a few weeks, while many small, indurated round ulcers may give even obstructive symptoms for years, and this also applies to cancer. Within two weeks of the onset of disability I have seen a patient exhibit general carcinosis, with a large primary mass in the stomach. Another patient may have noticed an epigastric nodule for a year, and yet laparotomy demonstrates a small mass well-confined to the wall of the stomach.

The average length of time of all symptoms in our 182 cases clinically satisfying the symptom-complex of cancer was 7.1 months. Of this group the shortest history extended over but two weeks and the longest was about three years. In nine cases (1.6 per cent.) cancer of the stomach was found at exploration, when there had been no previous indications of gastric disorder. Such cases have been described by Osler,[8] Chesnel[9] and others.

Of the 239 cases clinically furnishing the symptom-complex of chronic gastric disorder previous to the period of evident malignancy, the average duration of symptoms was 11.4 years. In this group the average duration of the supervening malignant course was 6.1 months. It seems thus manifest that the periods of downward progression closely approximate in the two classes of cases, wholly independent of the earlier gastric history of the person. From our knowledge of disease processes in general, it would seem scarcely possible that the "primary" cases of cancer mentioned before existed for any considerable length of time without giving clinical evidences of their presence. Especially is this emphasized when we are aware that between 60 and 70 per cent. of all proved cases of gastric ulcer and gastric cancer are so located in the visceral wall as to early interfere with the stomach's emptying power. I have been frequently impressed by the fact that many so-called "primary" gastric cancers in the early weeks of their disturbance gave clinical symptoms that are commonly ascribed to chronic ulcer.

3. The demonstration that a long-standing gastric disturbance which is later shown to be malignant was ever benign leads largely into realms of speculation. The chief arguments in support of this supposition appear to be the following:

A. After gastro-enterostomy for chronic ulcer, when the ulcer is not excised, it is stated that such a person rarely develops gastric cancer (Paterson,[10] Gressot[11] and others). The argument loses much of its force when we recall that in such a patient the entire physiology of the stomach and related viscera may have been upset. It is well recognized by able surgeons and physiologists that gastro-enterostomy is more than a simple procedure of "drainage." In the large majority of gastric extracts from stomachs when gastro-enterostomy has been performed, it is possible to demonstrate, chemically or microscopically, both duodenal and jejunal contents. Just what effect these foreign substances have on gastric ulcers or gastric cancers we have yet no means of knowing. We do know, however, that the parts of the alimentary tract from which they come are rarely affected with cancer. In our series of cases of gastric cancers, there are four patients which later developed cancer following gastro-enterostomy for ulcer. It also seems to hold that in cases of gastric cancer in which no pyloric obstructions are demonstrable gastro-enterostomy grants a longer lease of life than when such operations have not been performed.

B. Duodenal ulcer of the indurated type is a relatively more common affection than is gastric ulcer, yet carcinoma of the duodenum is a rarity. It is held that if cancer develops on chronic ulcer a great frequncy of its duodenal incidence should be expected. That the duodenum has a protective mechanism against malignancy appears to be shown by the surgical observation that only rarely does cancer at the pylorus, on the stomach side, pass to the duodenum by direct extension. In our series only four such instances were noted. The difference in the character of the tissue in which the chronic ulcer is implanted is also demonstrated by the fact that it is not uncommon to find that primary ulceration of the duodenum which extends up to the pylorus, assumes malignant characteristics on its gastric side while the ulcer on the duodenal side remains benign. There are six such cases in our series. We have also five cases in which malignant gastric ulcer was demonstrated together with benign calloused duodenal ulcer. Cancers of the duodenum occur in the great majority of instances, about or below the papilla of Vater. It is well known that this region of the viscus suffers traumatism from gall-stones, altered secretion of the liver and pancreas and from infective processes of the gall-tract. The upper part of the duodenum, where ulcer is common, is relatively immune to these influences, and also from the intense acidity and the associated peptolytic power of the gastric juice, which may irritate gastric ulcers.

C. Pathologists readily grant that there is a type of gastric affection which they class as "ulcus carcinomatosum." They demonstrate this generally at post-mortem. They do not, however, demonstrate why this type of ulceration exists, by revealing any characteristic changes in the gastric mucosa in which it occurs, nor do they show that from its beginning it was ever anything but malignant. They are willing to grant that it is something different from primary cancer which later ulcerates, but just what that difference is they do not state. This type of affection appears curiously to exist as an isolated entity with no explanation of its existence or prophecy as to its future course.

D. Clinicians hold that malignant ulcer exists in from 3 to 6 per cent. of all ulcers of the stomach (Fenwick,[12] Rosenheim[13]). The various observers, however, do not detail just how to segregate this group clinically from chronic gastric ulcer, nor do they offer suggestions of guidance for the determination of just what chronic ulcers are destined to pursue a benign course.

In our series there were 239 cases which, up to within an average time of 6.1 months before being absolutely demonstrated as cancer, showed nothing to indicate that were a laparotomy to be performed in that period anything other than chronic calloused gastric ulcers would be found. Only the subsequent course or the examination of fresh tissue at operation revealed the true nature of the affection. In this group of cases cancerous ulcers were found on laparotomy in 105 (43.9 per cent.) and extensive carcinomas, with or without ulceration, in 134 (56.1 per cent). Of the 183 cases with a clinical history of primary carcinoma, ulcus carcinomatosum was demonstrated in 28 (15.8 per cent.), while in 154 (84.2 per cent.) extensive growth was found. Of the 106 cases with clinical history of irregular gastric ulcer in the precancerous stage, ulcus carcinomatosum was shown in 22 (20.7 per cent.), and in 84 (79.2 per cent.) extensive involvement, with or without secondary ulceration.

These observations suggest several points. Development and careful interpretation of the early—the precancerous—history permits patients coming to laparotomy at a stage when in more than one-half of the instances the maximum advantage of localization of the disease is available, and hence the maximum benefit accrues to the individual case. In about one-fifth of the cases of so-called primary gastric cancer ulcus carcinomatosum can be demonstrated at operation, and these appear to be generally favorable cases for operative procedure, compared to their fellows. This is especially to be emphasized inasmuch as it has been shown by MacCarty and Blackford[14] that time-duration of symptoms bears no apparent relation to the size and extent of involvement of the lymph-nodes, and that the operative and subsequent mortality are in direct proportion to the amount of involvement of the lymph-nodes.

It would appear from the brief consideration of the objections to the interpretation of the so-called "precancerous" history with respect to the succeeding neoplasm having developed on earlier chronic gastric ulcer, as emphasized by Graham, that so far as we can judge clinically, the careful development of such history furnishes extremely valuable diagnostic and prognostic information. It would appear from the facts submitted that such interpretation allows the greatest degree of operative benefit with the minimum of operative risk. These facts have especially to be considered when we recall that we have no better clinical guide and that those who object to the significance of the "precancerous" history have nothing better to offer.

SIGNIFICANCE OF CLINICAL SYMPTOMS

Periodicity of Symptoms.—One of the strongest clinical evidences in the diagnosis of chronic gastric ulcer is the periodic recurrence of dyspeptic symptoms with perfect or fair health between the attacks. Graham,[15] Friedenwald[4] and I[1] have pointed this out. In 239 of the cases furnishing the material for this report in which there was a precancerous history of digestive disturbance, 81 per cent. complained of attacks of discomfort in that period, in 13.3 per cent. the attacks were of rare occurrence, and 4.7 per cent. had had continuous disturbance. When the period of malignancy supervened on the dyspeptic storm the affection was continuous and progressive in more than 99 per cent., irrespective of the earlier history. In the 182 cases making up the "primary" cancerous group, continuous disturbance was noted in 95.1 per cent. and frequent periodic attacks in 4.8 per cent.

[14] MacCarty and Blackford: Ann. Surg., June, 1912, p. 811.

[15] Graham: Prominent Symptoms in the Diagnosis of Gastric and Duodenal Ulcers, THE JOURNAL A. M. A., Aug. 22, 1908, p. 651.

Types of Pain.—In the group of cases comprising cancer following previous dyspepsia, severe pain and colics were noted in 23 per cent., steady ache in 48 per cent. and abdominal discomfort in 28 per cent. In the primary cancer group colicky pain was noted in but 6.6 per cent., steady ache in 32.4 per cent., and vague discomfort or "bloat" in 56 per cent., while in 4.3 per cent. there was no abdominal discomfort whatever. Opiate relief of pain was required in 6.5 per cent. of the first group of cases and in 2 per cent. of the second group.

Food Relation of Abdominal Pain or Distress.—In the diagnosis of chronic gastric ulceration, the relief of discomfort by the ingestion of food (if this form of relief be fairly constant) is granted to be a most valuable diagnostic sign. In a chronic dyspeptic its continuous presence is often almost pathogenic for ulcer. At the stage when the cases in our series came under observation, of the dyspepsia-preceding-malignancy group, food ease was present in 20.9 per cent., food aggravation in 46.4 per cent., food of negative significance in 27.4 per cent., and uncertain in 5.1 per cent. In the group of primary cancers, food ease was noted in but 3.2 per cent., food aggravation in 57.6 per cent., food of negative significance in 36.8 per cent., and of uncertain effect in 2.1 per cent.

Hemorrhage.—Intermittent bleeding, melena or hematemesis, is considered as almost conclusive evidence that peptic ulcer exists. While only but from 22 to 40 per cent. (Friedenwald,[4] Smithies[1]) of gastric ulcers bleed, yet when hemorrhage occurs, other things being equal, it is clinically assumed that ulcer is present. In the series of cancers here analyzed, hemorrhage was noted in 97 cases. Of the group designated by history symptomatology as malignant, following ulcer, hemorrhage occurred in 62.9 per cent.; in the group styled from early history "irregular" ulcer hemorrhage occurred in 19.5 per cent., while in the group of "primary" cancers hemorrhage occurred in 16.5 per cent. Of the whole number bleeding, 52 per cent. bled at least two years prior to their coming under observation, while 42 per cent. had bled within two years of that time. In 6 per cent. the time of hemorrhage was not determined. Of those who bled within the two-year period, 77.5 per cent. comprised cases in the non-primary cancerous group.

Anemia.—Of one or more estimations of hemoglobin in 250 of the cases, the average hemoglobin was 69.6 per cent. for the primary cancerous group and 67.2 per cent. for the dyspepsia-before-cancer class. The average for the series was 68.1 per cent.

Vomiting.—Of the entire series 326, or 57.5 per cent., of the cases vomited, and of this number 57 per cent. vomited daily. Of the series, 132 (40.5 per cent.) exhibited delayed vomiting. In but 58 (15 per cent.) was the vomitus dark or "coffee-ground."

SIGNIFICANCE OF PHYSICAL EXAMINATION

Tumor or ridge in the abdomen (generally epigastric) was demonstrated in 411 instances (72.6 per cent.). It was movable in 63.6 per cent. Of the primary cancerous group tumor was present in 39.8 per cent., while in the ulcer-cancer class it was shown in 60 per cent.

Metastases were demonstrated in eighty-six cases (14.7 per cent.) before laparotomy and were, in the order of frequency, rectal and pelvic, cervical and axillary, navel and abdominal wall, and in the groin. In the primary cancerous group, metastases were present in 20.8 per cent. and in the non-primary class in 13 per cent. When such metastases were present, the cases were generally inoperable.

SIGNIFICANCE OF TEST-MEAL FINDINGS

The Ewald test-breakfast is used in the Mayo Clinic. It is preceded twelve hours by a motor-meal after the suggestions of Strauss and Hansmann. Routine quantitative and qualitative estimations are performed by the Topfer method.

There is not space here to go into elaborate detail of the information derived from examination of gastric contents in our series of 566 cases of cancer. A few of the more important points will be detailed, and the complete report reserved for a subsequent paper.

Food Remnants.—Motility was interfered with in 73.9 per cent. of the entire series. Of the primary cancerous group, remnants were present in 64.8 per cent. and in the non-primary class in 74.2 per cent.

Acidity of Gastric Extract.—In the primary cancerous group there were 55.4 per cent. of cases in which hydrochloric acid was absent, in 11.5 per cent. hydrochloric acid was between 20 and 50. In this group 79 per cent. had total acidity under 50, and 84 per cent. had combined acidity and acid salts under 50.

In the non-primary cancerous group, free hydrochloric acid was absent in 49 per cent., in 20 per cent. it was between 20 and 50, and in 46.3 per cent. it was under 50. Total acidity was below 50 in 78 per cent., and combined acidity and acid salts below 50 in 90 per cent.

Lactic Acid.—In the primary cancerous group this was demonstrated in 52.2 per cent., while in the non-primary class it was present in 44.9 per cent.

Occult Blood.—This was shown (benzidin or guaiac tests) in 73 per cent. of the primary cancerous class and in 77 per cent. of the non-primary group.

Microscopic Examinations of Gastric Extracts.—These were made on the last 146 cases of gastric carcinoma by the agar-differential-stain method devised by me.[16]

Oppler Boas Bacilli.—This form of organism was demonstrated in 93.8 per cent. of all the cases. In this same series, yeasts were shown in 50.7 per cent. and sarcines in 17 per cent. Oppler-Boas bacilli and yeasts were combined in 30 per cent., Oppler-Boas bacilli and sarcines in 10 per cent. and Oppler-Boas bacilli together with yeasts and sarcines in 9.2 per cent. Cells showing atypical mitoses were present in 5 cases.

Special Tests.—In 141 instances of demonstrated cancer the glycyltryptophan test was made. It was positive in 40 per cent.

In thirty-one cases the hemolytic reaction to alien erythrocytes *in vitro* was positive in 47.2 per cent.

Woodyatt and Jacques[17] have recently pointed out that in gastric cancers and ereptic ferment, as estimated by the modified formaldehyd titration method suggested by Sorenson and Schiff,[18] can be demonstrated in excess in the gastric extract that has been passed through a

Berkefeld filter. Our experience with the original procedure is briefly summarized as follows: The average formaldehyd index of 57 cases of gastric cancer was 21; the average index of 40 cases of benign gastric ulcer was 10.8 and the average index in 75 cases of duodenal ulcer was 11.9. In 17 cases of achylia gastrica, the average formaldehyd titration index was 14.1, of 10 cases of pernicious anemia, 14.5, and in 5 cases of carcinomas of the liver, 4.25. It would appear that in some instances, the estimation of the ereptic power of gastric juice toward peptone solutions is of some value when taken in consideration with clinical history and symptomatology.

Wolffe-Junghans' Test for Soluble Albumin.—By this quantitative estimation method we have made 260 tests on gastric extracts showing achylia or free hydrochloric acid below 20, from cases in which there was no twelve-hour retention. There were eighty-three cases of gastric cancer in the series. The reaction was positive in 86 per cent. In this group there were 20 cases of lesser curvature and cardiac malignancy, and the reaction was positive in 75 per cent. Of 11 cases of ulcus carcinomatosum without gastric retention the reaction was positive in 10 cases, or 90.9 per cent. In 11 cases of extragastric carcinomas (liver and gall-tract) the reaction was positive in 54 per cent. In 10 cases of pernicious anemia, the reaction was positive in 10 per cent; in 17 cases of achylia gastrica, positive in 17 per cent. It would seem that this test is of value when taken in consideration with other evidence in carcinomas not associated with pyloric obstruction or palpable tumor, for example, growths at the cardia, the fundus, high on the lesser curvature, and on the posterior wall, and in cases in which a large carcinoma, with considerable induration, holds a pylorus open.

We have not found either the colloidal nitrogen or antitryptic estimations of practical value.

Roentgen-Evidence.—About 10 per cent. of ulcers and cancers are anatomically so situated as to prevent positive general clinical recognition. They are usually on the lesser curvature, high, at the cardia, fundus and on the posterior wall. In this type of case the fluoroscope and roentgenogram often localize definitely a process and turn a clinical doubt into certainty.

SURGICAL CONSIDERATION

Location.—In 210 cases (39 per cent.) the ulcus carcinomatosum or the growth was at the pylorus; in 27.1 per cent. on the lesser curvature near the pylorus; in 19.3 per cent. general; in 7.2 per cent. on the posterior wall, and in 4.2 per cent. at the cardia. The greater curve was involved in 1.1 per cent., the fundus in 0.75 per cent. and the anterior wall in 0.37 per cent. In nine cases there were simple and malignant ulcers associated in the same stomach, and in five cases simple duodenal ulcer and malignant gastric ulcer.

The figures for location are to be contrasted with those of Welch,[19] Brinton,[20] Lebert[21] and others. These authorities observed generally the terminal results of cancer of the stomach, nor were their observations always in a consecutive series, examined by uniform procedures. To any one who has had access to post-mortem material the difficulties connected with primary localization of gastric neoplasms need not be explained. The localization figures of our series, however, closely correspond to the location of chronic, calloused gastric ulcer, as shown by the tables of Welch[22] and myself.[1]

Lymph-nodes were involved in 71 per cent., irrespective of the early or late history. In 22.2 per cent. there was no lymph-node involvement and these cases were, as a rule, favorable for operation. Free fluid in the abdomen was present in 3.9 per cent.; these were inoperable cases.

There were sixteen cases in which a carcinomatous ulcer had been previously excised, but in which the involvement of the lymph-nodes (often microscopic only) had been noted—in which the person later returned with huge inoperable masses in the epigastrium.

Twelve per cent. of the patients died within six months following operation, but 36.6 per cent. remained well for more than three years, and 22 per cent. remained well over five years.

PATHOLOGY

It is not feasible to give here a detailed description of the specimens secured at laparotomy in this series of gastric cancers, and only a gross summary will be made.

The specimens were first examined in frozen section within a few minutes after their removal from the patients. They were next fixed in Melinkow's modification of Kaiserling's fluid and again sectioned and examined.

Types of Growth.—Adenocarcinomas were demonstrated in 556 instances (98.2 per cent); colloid carcinomas, 5 times; fibromas, 4 times, and sarcoma once. In 155 instances (27.4 per cent.) ulcera carcinomatosa were shown. These may have been primarily such, had formed from previous chronic ulcer or had resulted from surface proteolytic ulceration of preceding cancer. It is often impossible to say, without clinical history or test-meal findings, whether an ulcus carcinomatosum developed as such or whether it is a secondary result of a "primary" cancer. At the present stage of our knowledge, the surgical pathologist can positively say only that in a given specimen of chronic, indurated gastric ulcer, *cancer is or is not present.* There appears to be a borderline class, however, in which surgical pathologists of the widest experience in the examination of fresh tissue can often distinguish cellular arrangement or intracellular change of such nature as to warrant their stating that the process is "precancerous." Not infrequently the subsequent course of the ailment bears out the histologic prophecy.

In the experience of Wilson and MacCarty,[6] 71 per cent. of 153 cases of undoubted gastric carcinomas presented gross and microscopic evidence of previous ulcer. These observers also demonstrated that 68 per cent. of resected chronic ulcers of the stomach and duodenum (the latter furnishing a very small proportion of cases) were associated with cancer. In several instances MacCarty noted that the presence of erosions, simple round ulcer and ulcus carcinomatosum in the same specimen suggested possibilities of transition corresponding to that shown by Woolley[23] in cases of adrenal tumor. MacCarty has emphasized the difficulties of always differentiating between simple hyperplasia and malignant hyperplasia. He suggests that hyperplasia is a forerunner of malignancy, that hyperplasia varies in degree, that cancer is malignant hyperplasia, which also varies in degree, and that some degree of both processes are indistinguishable, histologically. This view is well within the opinion of Adami.[24] It seems to be partially substantiated by the recent work of Drew[25] and Levin[26] in experimental tissue proliferation and inoculation of malignant tumors.

Association of Malignant and Benign Processes.—In this series of gastric cancers there were five instances of simple ulcer of the duodenum associated with malignant gastric ulcer. In nine cases, simple and malignant ulcers were found in the same stomach. Independent cancer of the stomach and of the duodenum was demonstrated once. There were two cases of multiple gastric cancers. Six times it was observed that malignant gastric ulcers stopped sharply when duodenal mucosa was reached, but in seven instances of extensive gastric cancers it was shown that the duodenum was secondarily involved by direct extension.

SUMMARY

1. A number of cases clinically admitting only a diagnosis of chronic gastric ulcer are shown to be malignant at operation. Many cases of gastric cancer reveal a "pre-cancerous" history which at any stage prior to the terminal period of malignancy satisfies the clinical symptom-complex of chronic gastric ulcer.

2. A study of 566 consecutive cases of gastric cancer, operatively and pathologically demonstrated, has been made in the attempt to determine how frequently chronic ulcer precedes gastric cancer and how this change is manifested clinically.

Clinical Consideration.—The sex ratio in gastric cancer is approximately that of chronic gastric ulcer (3.1 males to 1 female). More than three-fourths of the cases of gastric cancer occur in persons between the ages of 40 and 70 years; more than one-half those of chronic gastric ulcer (134 cases) between the ages of 40 and 70. A family history or one of blood-relationship of gastric cancer existed in 9.2 per cent.—a history of tuberculosis in 1.2 per cent.

Precancerous history indicates that 41.8 per cent. of proved cases of gastric cancer presented early symptomatology of chronic gastric ulcer; 18.7 per cent. showed the early symptomatology of "irregular" gastric ulcer, and 32.1 per cent. of the cases had the symptom-complex of gastric cancer, without previous gastric malfunction. Thus in more than 60 per cent. of the cases of gastric cancer the patients had previous dyspeptic history and this history was generally that of chronic gastric ulcer.

The length of time of all symptoms of the "primary" cancerous group (182 cases) was 7.1 months. The average length of time of the precancerous dyspeptic period in 239 cases was 11.4 years. In this group the supervening period of evident malignancy averaged 6.1 months.

Development of precancerous history permits patients coming to laparotomy at a stage when in more than one-half of the instances surgical advantages of a localized process are available. In about one-fifth of the cases of "primary" gastric cancers, ulcus carcinomatosum is demonstrated operatively.

Significance of Clinical Symptoms.—Periodicity: In 81 per cent. of the cases in which prolonged dyspepsia had preceded cancer, periodicity of symptoms was noted in that stage, while in 99 per cent. of the cases periodicity was absent when the process became evidently malignant. In but 4.8 per cent. of 182 cases of "primary" cancer were there periodic attacks of distress.

Types of Pain.—Nearly one-fourth of the patients in whom dyspepsia preceded malignancy had prostrating pain (colics, etc.), while only about one-fifteenth of the patients with "primary" cancer exhibited this type of distress. Opiate relief was required in 6.5 per cent. of the former class and in 2 per cent. of the latter.

Food ease of pain was present in more than one-fifth of the cases in which malignancy followed clinical chronic gastric ulcer and in 3.2 per cent. of the "primary" cancer group.

Hemorrhage.—Melena or hematemesis was noted in 17.1 per cent. of the cases. Of the group styled malignancy following ulcer, hemorrhage occurred in 62.9 per cent.; in the "irregular ulcer" group before malignancy, in 19.5 per cent. and in "primary" cancer group 16.5 per cent. Of patients bleeding within two years of coming under observation, more than three-fourths fell in the ulcer-before-cancer classification.

Hemoglobin estimation was rather higher in the primary cancer group than the ulcer-preceding-malignancy class.

Vomiting was observed in more than 57 per cent. of the cases of gastric cancer. More than 40 per cent. exhibited delayed vomiting. Of the entire group, 15 per cent. gave a history of dark or "coffee-ground" vomit.

Nearly three-fourths of the cases of gastric cancer exhibit abdominal tumor or ridge. This is present in nearly two-fifths of the cases of "primary" cancer and more than three-fifths of the cases in which ulcer preceded malignancy clinically.

In more than one-fifth of the cases in the "primary" cancer division and in about one-ninth of the cases in the non-primary group, metastases were demonstrated before laparotomy

Test-Meal Findings.—Delayed gastric emptying power was evidenced in nearly two-thirds of the cases in the primary cancer class and in nearly three-fourths of cases in the non-primary division.

Acidity.—In 55.4 per cent. of primary gastric cancer cases free hydrochloric acid was absent; in 11.5 per cent. it was between 20 and 50.

In the non-primary cancer class free hydrochloric acid was absent in 49 per cent. and in 20 per cent. it was between 20 and 50.

Lactic Acid.—This is more commonly noted in the primary cancer group than in the non-primary division.

Occult Blood.—This is rather more frequently demonstrated in the non-primary cancer class than in the primary cancer group.

Oppler-Boas Bacilli.—These were demonstrated in 93.8 per cent. of cases of gastric cancer by the differential agar-stain method.

Glycyltryptophan Test.—This was positive in 40 per cent. of the cases (141). The *hemolytic* reaction was positive in 47.2 per cent. of the cases (31). The *formaldehyd titration index* was uniformly higher in gastric cancer and ulcera carcinomatosa than in other gastric ailments. The estimation of soluble albumin by the *Wolff-Junghaus test* was more uniformly positive in cancer and carcinomatous ulcer cases than other forms of gastric disturbance.

Roentgen-Ray Evidence.—In about 10 per cent. of the cases of gastric cancer evidence returned by fluoroscope and roentgenogram is of distinct value in making absolute diagnosis of physically inaccessibly located cancers.

[25] Drew: Jour. Path. and Bacteriol., July, 1912, p. 42.
[26] Levin: Jour. Exper. Med., 1912, No. 12, p. 149.

Surgical Consideration.—The locations of ulcera carcinomatosa and cancer as shown by laparotomy closely approximate those of chronic gastric ulcer, but do not correspond to the post-mortem localization of gastric cancer. More than one-fifth of the cases of gastric cancer revealed no involvement of the lymph-nodes, with generally favorable operative outlook. In nearly 4 per cent. free abdominal fluid was present. These were inoperable cases.

Pathology.—More than 98 per cent. of gastric cancers were adenocarcinomas. Sarcoma occurred but once in 566 cases. More than one-fourth of gastric cancers show ulcerative changes, as primary or secondary type of growth. It is usually an easy matter to state definitely whether or not a given specimen is at the time benign or malignant. There is a group of cases of chronic ulcer in which examination of fresh tissue reveals cellular or intracellular variations of such type as to warrant designation of "precancerous" ulcer. It is often impossible to distinguish stages of simple and malignant hyperplasia histologically. Benign ulcers of the duodenum may be associated with malignant gastric ulcers. Benign and malignant ulcers may be associated in the same stomach.

THE MEDICINE OF OUR FOREFATHERS *

JAMES J. WALSH, M.D., PH.D., SC.D.
Professor of Physiologic Psychology at the Cathedral College, New York
NEW YORK

In talking to the oldest medical society in this country it has seemed to me that no subject would be more suitable than what our forefathers accomplished in medicine. Our generation has become so accustomed to lauding itself as "the heirs of all the ages in the foremost files of time" and therefore so far ahead of the past that really our forefathers were to be pitied because they did not live to see our glorious time, that I have sometimes taken a little almost malicious pleasure in pointing out how many of the things that we think new are indeed very old. Anesthesia and antisepsis, sometimes looked on as the triumphs of our time, were anticipated by preceding generations in very striking ways. Tom Middleton, the English poet of the seventeenth century, has spoken of "the mercies of old surgeons who put their patients to sleep before they cut them," and we have the records of two or three forms of anesthesia during the thirteenth and fourteenth centuries, at least one of them by inhalation. Strong wine was used as a dressing for wounds, and the surgeons effected union by first intention and boasted about it (we owe that Latin expression "first intention" to them), and even declared that surgeons whose wounds suppurated when they were made through an unbroken skin surface were responsible for the evil results that followed.

Indeed, practically the whole of our surgery which we have been inclined to think of as the particular development of our generation was anticipated in the long ago. Operations were done on the skull for abscess and tumor in the brain, on the thorax for the pus and other fluids, and on the abdomen for all sorts of internal conditions. Particularly the surgeons operated for the radical cure of hernia, employed an exaggerated Trendelenberg position in order to have the intestines drop away from the site of operation, fastening their patients' heads down on a slanting board and in general solving the technical problems very much as we do by special sutures, by the use of wire auxiliaries and other things of that kind. Hugo von Pfolspeundt invented a flanged tube which he inserted into the intestines when they were badly wounded, bringing the intestines together above them and asserting that the tube would be passed out, but not until after such intestinal agglutination had taken place as would prevent the extravasation of the contents of the intestine. This anticipation of the Murphy button five centuries ago is interesting but not so striking as the use of the trachea of an animal for this purpose of which we have a description, the inventor declaring that the trachea would be gradually disintegrated, but not before aglutination of the edges of the wound would take place.

As a matter of fact, after considerable study of the history of medicine as well as other phases of human intellectual activity, I have come to the conclusion that whenever men deliberately and seriously face any problem they solve it about as well as at any other period in the history of medicine. While we talk much of progress, let us not forget that in the great phases of intellectual achievement there is no such thing as progress, but on the contrary abundant evidence of decadence. No one thinks for a moment of saying that there is progress in literature or that the writers of our time are doing anything that is serious or likely to endure. Not long since the New York *Times* declared on the occasion of the death of Mark Twain that of the four men who had international reputation in literature, that is, who in our generation had been read generally outside of their own countries, three were now dead. The four were Zola, Tolstoi, Mark Twain and then the living one, Rudyard Kipling. Kipling, like Jeffries and some others, has not "come back" and the list is interesting therefore as showing the caliber of our literary achievement. Our poets are such minor poets that the less said about them the better. Our dramatic literature is almost literally a farce when it is not an obscene joke. There has not been a new idea in architecture for four hundred years. Painting, sculpture and the arts and crafts look to the past for models. In everything of this kind we are imitators.

Over and over again men have faced human problems seriously and have accomplished good results. They have done so whenever in humility of heart they have realized that good work does not come of itself or by any inevitable law of progress, but by maintaining high ideas and ideals and working them out patiently. Whenever men have observed for themselves, drawn their conclusions patiently and without haste avoided theorizing and the hasty overconclusiveness so characteristic of youth, they have done things. Unfortunately as Europeans sometimes say in all kindliness of heart, "You Americans are so delightfully, refreshingly, poignantly, unconsciously young."

Even here in America, however, we must not think that this is the first time that good work has been done; and if on an occasion of this kind I should be tempted to go back for about a hundred years I would be able to show you some of the things that men were thinking and doing in this country that are anticipations of what we are inclined to think of as our most recent discoveries.

Probably the discovery that we have most reason to be proud of here in America in our time is that by which we know that yellow fever is not spread through the air, or by fomites, but is distributed by the mosquito. The other day I was looking over an old pamphlet which shows how much an observer of a hundred years ago here in America anticipated the most important portion of that discovery by some notable observations and really surprising experiments undertaken to demonstrate the value of his observations. I quote from "A Memoir on Contagion More Especially as It Respects the Yellow Fever," read in the convention of the Medical Chirurgical Faculty of Maryland, June 3, 1817, by Nathaniel Potter, M.D.:

---

* Address delivered, in part, at the annual banquet of the New Jersey State Medical Society at its annual meeting, June 11, 1913.

> During the prevalence of the yellow fever in this city in the years 1798, 1800 and 1802, we proposed and executed several experiments adapted to the question of contagion. On September 20, 1797, having been called on to visit a man in the act of dying, covered with perspirable matter, I applied a piece of muslin to his body till it became saturated, and in this condition, half an hour after, bound it around my head at bedtime. The fetor was nauseous in the extreme and occasioned a transient sensation of sickness of stomach; but, being languid from excessive exercise during the day, a profound sleep succeeded, from which I did not awake till 7 o'clock the next morning. I experienced no further inconvenience. In 1798, a few sporadick cases occurred in Baltimore. I inoculated myself with the perspirable matter that adhered to the skin of a patient in the last stage of yellow fever, but experienced no other effect than that which followed the punctures made in both arms. As the few cases that occurred this year assumed an uncommonly malignant aspect and many of them were accompanied by inguinal buboes, I availed myself of the occasion to inoculate myself with the matter formed by suppuration. On October 11, I inserted the matter in both arms, taken from the groin of Mr. Rector Lowe. A slight circumscribed redness appeared about twenty-four hours after the operation, and continued nearly stationary for four days. As no irritation proceeded from the punctured parts, and the rubefacience evidently declined on the fifth day, I concluded that the local appearances ought to have been ascribed to the puncture, or the acrimony of the pus.
>
> It has been suggested, that as the stomach is one of the principal organs invaded by inflammation in this disease, and as the black vomit would appear to be a secretion from that organ, that the disease might be reproduced by receiving this secretion into a healthy stomach. The experiments of Dr. Ffirth have decided that this hypothesis is visionary. He swallowed the black matter in the state it was ejected from the stomach, but with perfect immunity from disease. That this fluid cannot propagate the disease when brought into contact with the nerves of the skin, we have ascertained by reiterated experiments.

Dr. Potter argues that quarantine against yellow fever is useless and indeed absurd and as applied tyrannous. He is quite sure that the affection is carried through the air and cannot be kept out by any quarantine measure. It was not carried, however, by respiratory effluvia or fomites because patients suffering from yellow fever in hospitals did not communicate it to those near them. He argues from this that other infectious diseases also cannot be kept out by quarantine. He mentions particularly the plague and typhus fever. He protests vigorously against the imposition of quarantine and quotes the opinion of Jefferson who, on the strength of investigations made with regard to yellow fever, advised strongly against quarantine laws. The conclusions of course are too wide. Yellow fever spreads through the air, but by means of the very material mosquito and not through some more tenuous medium. Plague also spreads through the air, but by the medium of the flea. The air-borne diseases are a thing of the past in his sense of the word and yet he anticipated with regard to the one disease that was under his observation our most recent conclusion, and if he had not insisted on drawing his conclusions so widely would have been far in advance of his times. Generalizations nearly always fail in medicine.

It so happens that in the same bound volume of pamphlets at the Surgeon-General's Library, for it is to them that I owe the privilege of quoting this monograph, there is an announcement of Dr. David Hosack of New York of the "Course of Studies Designed for The Private Medical School Established in New York by David Hosack, M.D.," professor of the theory and practice of medicine and of midwifery and the diseases of women and children (New York, printed by Van Winkle, Wyelie & Co., 1816). In this, "to those students who have not received a liberal education, the following works are recommended previously to the commencement of their medical studies":

RHETORIC AND BELLES LETTRES

Murray's "Grammar" (large edition).
Blair's "Lectures on Rhetoric."
Duncan's "Logic."
Campbell's "Philosophy of Rhetoric."
Gregory's "Letters on Composition."
Kett's "Elements of Human Knowledge."
Barron's "Lectures on Belles Lettres and Logic."
Gerard on Genius.
Gerard on Taste.
Alison on Taste.

GEOGRAPHY

D'Anville's "Ancient Geography."
Pinkerton's "Modern Geography."
Morse's "American Geography."

HISTORY

Priestley's "Lectures on History."
Tyler's "Outlines of General History."
Anquetil's "Universal History."
Miller's "Retrospect of the Eighteenth Century."

NATURAL PHILOSOPHY

Helsham's "Lectures."
Gregory's "Economy of Nature."
Cavallo's "Natural Philosophy."
Imison's "School of Arts."
Ferguson's "Astronomy."

MORAL PHILOSOPHY

Beattie's "Elements of Moral Science."
Beattie's "Essay on Truth."
Paley's "Principles of Moral and Political Philosophy."

> It is also recommended to the young gentleman, unprepared by a collegiate course of study, to attend at least one course of lectures on mathematics and natural philosophy, as delivered in Columbia College, and to devote an hour daily to the Latin, Greek and French languages, under the direction of a private teacher.

Dr. Hosack evidently had an excellent appreciation of what was needed to prepare a man for medical studies and a high ideal of what the medical student ought to know. Now that with much trouble and pains we have climbed back to the point at which we ask a single year of college work in the majority of the schools, Dr. Hosack's standard of a century ago should be thoroughly recognized. His three years of medical studies includes a range of medical reading at least as wide as any recommended now, and he even suggested the medical journals with which students were to become familiar. Dr. Samuel W. Francis was associated with him in the teaching, and both of these men were physicians of broad and deep scholarship. They were not unpractical idealists, however, for the announcement declares that a medical student is not expected to become familiar with all of these books but to know how much is expected of him, to occupy every moment and "thus seeing a plan of study before him he will remit no honorable exertion to its successful acquisition. The works of these distinguished writers will have taught him to appreciate the dignity and importance of his profession and in the intervals of practice he will be induced to complete whatever of this outline he shall have left imperfect." The private library of Dr. Hosack was constantly open to the student for reference. When we realize how much medical education had descended in the next generation so that two ungraded terms of four months each were offered to men without any suggestion of preliminary education, it is hard to understand how such things come about.

When writing the history of the New York State Medical Society about ten years ago I called attention to the fact that the essays which were awarded prizes by the Medical Society of the State of New York in 1825 and immediately succeeding years were such as might well win prizes at the present time. It would be easy to think that prize essays written at that time would have comparatively little interest except possibly to the historian and still less of practical value. The surprise, therefore, is to find that the subjects chosen are treated nearly from the same point of view as we would treat them at present and that, indeed, the writers anticipate many of the points of view that we are much inclined to think of as quite modern. The first prize given was awarded in 1825 for an essay by Dr. Andrew Hammersley.[1]

Dr. Hammersley begins by discussing and rejecting the popular idea that consumption is due to cold, or that indeed cold is a source of the many ills that are attributed to it. When we recall that even at the present time this is a popularly accepted notion, Dr. Hammersley's paragraphs are interesting.

> Popular prejudice has all along conduced to the belief that sudden exposure to cold, when the body is heated, would be attended with extreme hazard, and this alone has been accounted one of the fruitful sources of disease. The researches, however, of modern experimenters has tended in no small degree to qualify such conclusions.
>
> Those of Dr. George Fordyce and Sir Charles Blagden, familiar to every person, are among the most important in evincing that exposure to a high degree of cold, after violent heat, is unattended with danger to the constitution. This fact is likewise confirmed by the mode in which the practice of bathing is conducted in Russia, and in several other countries, the inhabitants of which, to heighten the luxury and add to the refreshment of immersion in heated baths, or long exposure to vapor of high temperature, immediately plunge into contiguous cold baths, or run into the open air and without the smallest covering on their bodies roll themselves in snow. In considering a fact of this kind, there are two particular circumstances to be noticed, to wit, the acquired vigor of the subject to whom the practice appertains and the inherent powers of reaction possessed by the animal economy. The hardy Russian, whose every fiber is made tense by the severity of his climate, suffers no harm from such practices, as the principle possessed by the system just adverted to is put in action in a frame capable of enduring the influence of the opposite medium to which it is exposed.

On the other hand, Dr. Hammersley is very certain that dust has a great deal to do with the development of tuberculosis, and he points out that it is particularly workmen whose occupations keep them in a dust-laden atmosphere and especially whose trades involve the making of much dust who are most likely to suffer from it. He says:

> Among the various artisans Dr. Cullen has enumerated stone-cutters, millers and flax-dressers as particularly subject to attacks of this disease. "But the most striking example," says another writer, "of this species of injury is afforded by one of the processes of the needle manufactory; it is that of dry grinding by which the needles are pointed; the persons employed in this labor are universally affected in a short time with the symptoms of approaching consumption. They go on coughing till they either spit blood or a thick substance having the appearance of matter. They decline in flesh and strength and scarcely ever survive to the fortieth year. Dr. Kirkland observes that scythe-grinders are subject to a disease of the lungs from particles of sand mixed with iron dust (getting into the lungs and setting up an infection) which among themselves they call the grinder's rot." It is moreover asserted on good authority that the filers of London die almost universally at a very early period of a similar disease. Certain other occupations are very properly thought to bestow an immunity from this extensive malady. Such are those of boatmen, watermen, sailors and gardeners. Certain animals of the lower order are moreover supposed to enjoy a marked exemption, as dogs; while on the other hand, cows, it is reported, are particularly subject to it.

In the last sentences he dwells on the fact that people who live in the outdoor air have an immunity to the disease to a considerable extent, and he discusses animal tuberculosis much in the same way that we were discussing it after Koch's announcement with regard to bovine tuberculosis at the beginning of the twentieth century.

The second prize essay was "The History, Causes and Treatment of Typhus Fever," by Dr. Alfred Y. Magill of Winchester, Va., and may be found in the Transactions of the Medical Society of New York for 1834-5. It might be thought that whatever there would be of interest in this essay would surely be contained in the discussion of the causes or perhaps of the history of the disease. As a matter of fact, it is under treatment that the part of the essay which is of enduring interest occurs. We think of the cold-water treatment of typhoid fever as modern, yet here is a thorough discussion of it in a prize essay nearly a century ago in which the writer confirms most of his conclusions from authorities who wrote more than a century ago.

Perhaps even more interesting than the use of cold water for the reduction of fever is the suggestion that when water was not available or was contra-indicated for any reason the patient should be put in the cold air until a definite reduction of temperature was secured. The opening of a window directly in the face of a cold northwest wind would remind one of some of the venturesome proceedings of physicians especially in hospital work in recent years. Dr. Magill said:

> No one can peruse Dr. Currie's recent experience in this matter without being convinced that cold water when properly applied is a most important remedy in case of fever. Its utility is not confined to typhus; it is equally serviceable in all fevers attended with increase of heat and arterial action. Its effect on the pulse is astonishing in many cases. We have often known the mere bathing of the hands and arms of a febrile patient to reduce the action of the pulse from ten to fifteen beats in the minute, and if this partial application of cold water has such an effect on the action of the heart, how

[illegible] Library
[illegible] Medical College

> much greater must be the effect of a cold bath. We have many instances on record of its calming at once the most furious delirium; persons in such a situation have often jumped overboard from a vessel into the sea and been taken up perfectly calm and rational and with an almost complete extinguishment of the fever. With the many strong instances recorded in various works of its remarkable efficacy in curing fever, it is justly a matter of surprise that physicians so seldom call its great powers into requisition. It exercises a more immediate control over the action of the heart than blood-letting. Dr. Currie mentions a striking instance of the effects of cool air in reducing the pulse. "In the month of May, 1801," he says, "I was desired to see a patient ill of fever in Sparling Street. I found him in the tenth or eleventh day of the fever, delirious and restless; the surface of the body dry, and his heat 104 F. The room was close and I desired the only window in it opened. The wind from the northwest blew directly into this window, and the bed being situated between it and the chimney, a pretty brisk stream of air passed over it. The patient had just thrown off a considerable part of his bedclothes and was exposed naked to the breeze. I sat by him with my finger on his pulse watching the effect. In a little time the pulse fell from 120 to 114 in the minute; he became more tranquil and soon afterward he sank into a quiet sleep, in which he remained when the water for effusion was prepared; of course we did not disturb him; he remained exposed to this cold air until morning when his pulse was found to be about 100 and his heat 101."

It is interesting to note that though the clinical thermometer was not often used for half a century after the date of this observation (indeed, Keen says that surgeons during the Civil War estimated fever by touch and not by the thermometer), this English observer quoted by an American prize essayist was studying his fever cases very carefully with the aid of a Fahrenheit thermometer in the early years of the nineteenth century.

While all patients suffering with fever were to have their temperature reduced by some direct use of cold air or water, he did not think that patients should be subjected to cold applications indiscriminately but advised the selection of patients and suggested certain contra-indications to this method of treatment. The whole discussion is interestingly up-to-date in many ways and deserves a place in our literature. He said:

> But cold water is by no means to be used indiscriminately in every case of fever; neither is it to be used in all stages of any fever; the rules which Currie has laid down on this subject are excellent and cannot be followed too closely. If we obey strictly his directions, we will always be prevented from misapplying or doing injury to its use. He gives separate rules for the external and internal use of cold water, but as its effect, except in degree, is the same when used either way, one set of rules will answer as a guide for both. His first general rule is that "it may be used (either internally or externally) when there is no sense of chilliness present, when the heat of the surface is steadily above what is natural, and when there is no general or profuse perspiration." We will now give the substance of the particular rules he has laid down on this subject: 1. Cold water is not to be used either internally or externally in the cold stage of the paroxysm of the fever, however urgent the thirst; taken at such times it increases the chilliness and produces great weakness of the pulse, and if used to any extent might cause the death of the patient. 2. When the hot stage is fairly formed and the surface is dry and burning, cold water may be used both ways with the utmost freedom; frequent draughts of cold liquid and its external application, under such circumstances, are highly grateful; they diminish very much the heat of the body and lessen considerably the volume and frequency of the pulse. 3. It is also necessary to abstain from the use of cold water when the body is under profuse perspiration, and this caution is more important in proportion to the continuance of this perspiration."

The third prize essay was on iodin, by Samuel J. Hobson,[2] M.D., a member of The Philadelphia Medical Society. Iodin has been used for many and varied ailments since Hobson wrote his essay, but there are no affections for which it was recommended in the centuries since, so far as I can find, that are not mentioned by the Philadelphia prize essayist about the end of the first quarter of the nineteenth century. All the glandular enlargements including the mamma, the liver, the spleen, the testicles, scrofula, dysenteric tuberculosis, bone and every other form of tuberculosis were all to be benefited by iodin. It is well worth the while reading that essay on iodin and comparing it with some of our text-books of materia medica and therapeutics which still carry wonderful indications of the most varied character for iodin.

The fourth prize essay was by Dr. James Conquest Cross and was on the subject of delirium tremens. It will interest the modern physician to know, though I am not sure that the detail has any historical value, that the prize winner, Dr. Cross, was from Kentucky and knew his subject very well. His history of the disease, its first description as an independent entity in 1801 and other details are of interest. He insists on individualization of the cases, deprecates the overuse of opium and discusses venesection and various antiphlogistic methods of treatment.

The fifth prize essay that has been preserved is that of Dr. Benjamin W. McCready of New York, who wrote on The Influence of Trades, Professions and Occupations in the United States, in the Production of Disease.[3] His was the prize essay for the year 1837. As I have already stated,[4] and shall repeat here, this was the first time so far as I know, that the prize was awarded to a New York man. Kentucky, Virginia and Pennsylvania had been represented in the list of prize-winners, and it is very evident that the prizes were awarded entirely for the merit of the essays and not for any personal or partial reasons. In this fifth essay the question of the overcrowding in the tenement house districts of New York City is discussed in the same terms that would have been used fifteen years ago on the same subject. The reasons for ill health in the tenement house districts are thus stated:

> In other cases the cupidity of landlords has tempted them to build up narrow alleys with small wooden tenements which, costing but little, and being let to numerous families, yield immense profits. The alley is often not more than 6 feet wide, paved with round stones and with very insufficient means for draining off the water. It is not uncommon in such situations to find one or two of the apartments in each house entirely underground. Can we wonder if in such a state of things we find moral as well as physical disease, vice as well as sickness? Can we expect men who live thus to be orderly and sober, or women to be cleanly and domestic? In such situations, during the summer months, diarrhea and dysentery are rife, and among children fatal. Scrofula, in some of its protean forms, is frequently met with and they form the lurking places where small-pox, measles and scarlet fever lie covered under the ashes, or when circumstances are favorable, blaze up into sudden fury.

At the end of Dr. McCready's essay there is a rather striking set of passages in which he discusses the evils of the quack and especially the patent medicine vender, and suggests the reasons for the popularity of their products. He has caught the essence of the idea in the declaration that the present popular errors in medicine are always the result of previous supposed knowledge among physicians themselves. Dr. McCready's remedy for this unfortunate state of affairs would be the spread of real knowledge. In the seventy-five years that have elapsed since the writing of this many improvements and advances in education have come, yet his words retain their forcefulness and application.

> That the present errors of the vulgar were formerly the themes of philosophers, is an old and trite observation. Most of the vague and unfounded notions of the public concerning the nature and treatment of diseases, which embarrass the young practitioner on his entrance into practice, were once the cherished doctrines of the wise and learned. Can we do nothing to correct the evil our predecessors have occasioned? Can we not substitute truth for falsehood, facts and reasoning founded on facts, for idle notions, and injurious hypothesis? I would not wish to instruct the community in a knowledge of the symptoms and treatment of diseases—that were impossible; but I would wish to make a knowledge of the laws and functions of the living body a necessary part of a liberal education, and to communicate to all classes so much information as would enable them to educate their children and regulate their diet, clothing, exercise and habitations.

Dr. McCready has also an excellent review of quack medicines which might apply to present conditions; and he thought the newspaper press as responsible for it then as we do now. The evil results to be anticipated from the abuse of medicines are just those that medical writers of the present day insist on.

> There is an evil, which has of late years become of excessive magnitude, and which is daily increasing—the consumption of quack medicines. Aided by the immense circulation of a cheap, press, many of these nostrums have obtained a sale that exceeds belief. Few patients among the lower classes now apply to a physician, who have not previously aggravated their complaints by swallowing numbers of these pretended specifics, and a late resident-physician of the city hospital has informed me that he has met with many cases of derangement and irritation of the mucous membrane of the stomach and bowels, caused solely by the drastic articles which enter into their composition. Formed in most instances of irritating ingredients and directed to be taken in immense doses, and as infallible remedies in all cases, the mischief which they do is incalculable, and unless some stop be put to the evil by law or by an enlightened public opinion, it will soon claim an unenviable preeminence as a cause of public ill health.

Surprising as it may seem to us because of the feeling that has been so commonly cherished of the wonderful advance that has been made in recent years in medicine, what we find when we know sufficient of the details of the history of medicine is that even here in this country many of the ideas that we are likely to think of as most recent were anticipated long ago, and discussed very sensibly by some of our grandfathers in medicine, though their ideas seem to have affected only a few of the thinking physicians in practice at the time. After all, it has probably always been true in the history of medicine that the ordinary practitioner of medicine was using conventional or routine remedies and modes of treatment and expecting much, but seldom realizing all that was being accomplished around him. Even in our own time this is probably much truer than is thought and indicates what possibilities for advance there is in medical practice. Even now the knowledge that we have with regard to cancer and its early diagnosis, as well as the early diagnosis of tuberculosis, is neglected to such an extent that it is only when patients are in advanced stages that an absolute diagnosis is made, and then their best chance for recovery is already gone.

Let us not forget that practically all our diagnosis of lung diseases was outlined in Laennec's book of auscultation nearly a hundred years ago, and that very little has been added to that. Even now, however, there are many physicians who do not apply this great discovery of Laennec in anything like the scientific way that it should be applied.

Instead of lying back on our oars then and thinking that the tide of progress will carry us with it inevitably, it is well for us to recall that at any time in the history of medicine thoughtful physicians have anticipated discoveries that seemed novel long after their time, and that indeed at any time men who have approached clinical problems seriously have done great good to patients in spite of any supposed lack of knowledge in their time. It is the thinking physician occupied with his patients and not with cases who represents the most important factor in every generation of medical history, and there is never anything absurd about that. After all, it is not surprising that physicians should have proved capable of solving so many problems so well in the past, for man has at all times solved his problems nearly as well as at any other time in the history of man. Our philosophy, our literature, our poetry, our architecture, our painting, our sculpture is nearly all old, and what is best is of the olden time. Why should not this be true with regard to medicine, at least to the extent that would make us realize that we have a glorious history of medicine, not for one or two generations but for many centuries and even for more than a century right here in America.

110 West Seventy-Fourth Street.

AN ETIOLOGIC STUDY OF HODGKIN'S DISEASE

PRELIMINARY NOTE *

C. H. BUNTING, M.D., and J. L. YATES, M.D.
MADISON, WIS.

In a recent publication[1] we have described a diphtheroid organism obtained in pure culture in four cases of Hodgkin's disease, and observed in three others. In order to determine the possibility of an etiologic relationship between this organism and the disease, the *Macacus rhesus* monkey has been used for inoculation experiments. While the experiments have been under way but a comparatively short time, histologic examination of a portion of a group of enlarged lymph-nodes, removed for transplantation to another animal, is of so encouraging a nature that a report seems justified. While we cannot yet claim that by the inoculation of the organism in question we have produced Hodgkin's disease (meaning the firm establishment of the organism in the animal and a continued and progressive enlargement of the general lymphadenoid tissue), we can say, that by repeated

* This work has been aided by a grant from the Rockefeller Institute of Medical Research.

[1] Bunting, C. H., and Yates, J. L.: Culture Results in Hodgkin's Disease, Arch. Int. Med., August, 1913, p. 236.

injections we have produced progressive enlargement of a single group of lymph-nodes which at the time of writing show histologic changes identical with those seen in the lymph-nodes of human beings, where the disease is of the same duration.

The culture used in inoculating this animal was obtained from a patient in the Mayo Clinic, Case 2 of our report, and is designated in the laboratory as Subculture X. F. A. In some of the later inoculations this was combined with a subculture recovered in pure condition from an abscess which followed inoculation of Monkey 3. This is the only case in which an abscess has followed inoculation of any of the animals. This culture had survived forty-eight hours in the monkey and it was thought might have acquired some tolerance. It is designated as Subculture X. F. A. M.

The record of Monkey 1, from which the tissue was removed, is as follows:

Monkey 1.—Rhesus, female, arrived from New York April 11, 1913.

April 15: Temperature 38.6 C. Red blood-cells, 6,680,000; white blood-cells, 22,300. Lymph-nodes in both groins somewhat enlarged. Two lymph-nodes palpable low down in right axilla, also in left axilla.

April 19: Temperature 38.7 C. Injection of the twenty-four-hour growth of culture X. F. A. on Loeffler's serum, diluted with normal salt solution, into right axilla.

April 21: Temperature 39.5 C. White blood-cells, 17,600.

April 22: Temperature 39 C. Two axillary lymph-nodes on right side much enlarged, apparently about 1 cm. in diameter.

LEUKOCYTE COUNTS IN THE MONKEY

Date	Total Count	N.	E.	B.	S. L.	L. L.	L. M.	Tr.
April 15	22,300	51.0	2.4	0.2	40.8	2.8	0.4	2.4

March 1	31,250	62.0	1.8	0.4	27.2	2.2	5.4	6.0
May 23	20,000	42.8	2.2	0.8	46.0	2.2	1.0	5.0
May 28	*	34.4	5.0	0.0	49.6	1.8	0.4	8.8
June 11	14,000	29.8	5.4	0.2	54.8	4.6	0.2	7.0
June 30	*	50.0	1.8	0.0	38.0	2.0	0.2	8.0
July 1	*	51.8	2.2	0.2	37.2	2.0	0.2	6.4
July 2	*	48.6	3.8	0.2	36.2	3.6	0.4	7.2
July 3	*	51.2	1.6	0.2	35.0	3.2	0.2	8.6
July 5	24,000	52.8	2.4	0.0	32.0	4.6	0.4	7.8

April 24: Temperature 38 C. White blood-cells, 14,000. Lymph-nodes in right axilla still enlarged.

April 26, 10 a. m.: Temperature 38 C. Von Pirquet test made on left arm.

April 28: There had been no reaction to von Pirquet test. Lymph-nodes in right axilla still enlarged.

May 1: Temperature 39 C. White blood-cells, 31,250. Lymph-nodes of right axilla still enlarged.

May 23: White blood-cells, 20,000.

May 24: Inguinal lymph-nodes somewhat enlarged. Moderate enlargement in left axilla. Two large lymph-nodes in right axilla. One twenty-four-hour slant on Loeffler's serum of Culture X. F. A. injected in right axilla.

May 27: Temperature 39 C. Marked induration in right axilla, involving enlarged lymph-nodes. The whole mass is about 2 cm. in diameter. Some oozing of serum along needle track. A smear from this shows the diphtheroid organism.

June 7: Marked enlargement of right axillary lymph-nodes. One twenty-four-hour slant of Culture X. F. A. injected into right axilla.

June 9: Marked induration in right axilla.

June 11: Induration lessening. Temperature 38.6 C. White blood-cells, 14,000.

June 21: Two twenty-four hour slants of X. F. A. injected into right axilla.

June 30: Lymph-nodes in right axilla large, surrounded by indurated tissue. Injection into right axilla of one twenty-four slant of X. F. A. and one of X. F. A. M.

July 2: Large lobulated indurated mass, roughly 3 by 3 cm. in right axilla. No leakage along needle track. No sign of softening or of abscess formation.

July 5: White blood-cells, 24,000. Induration of axilla marked, apparently increasing. Lymph-nodes involved, swollen and firm.

July 6: Portion of group of lymph-nodes in axilla removed under ether anesthesia.

The excised tissue consisted of a group of four lymph-nodes united by fairly firm moist connective tissue. Two of the lymph-nodes were approximately 15 by 7 mm., each, in size, while the other two were each just under 5 mm. in diameter. Portions of the tissue were fixed in formaldehyd solution and sectioned.

Histologically, the tissue between the lymph-nodes was found to consist largely of recently-formed connective tissue, with abundant fibroblasts. There is some polymorphonuclear infiltration.

The changes in the lymph-nodes are quite similar so that a description of one will suffice. There is no definite capsular thickening. The internal structure of the lymph-node is not yet lost, but is to a considerable extent obscured, owing to a loss of distinctness in the borders between the sinuses and the medullary cords and peripheral nodules. The germinal centers are large, and show numerous mitotic figures, yet there is a relatively narrow collar of lymphocytes about the center, but instead, the center shows many of the so-called large endothelial cells and they are present in numbers among the peripheral lymphocytes. The sinuses of the lymph-nodes are filled with cells of the endothelial type, and they are also scattered generally through the lymph-nodes in the lymph-cords. Mitotic figures are numerous in scattered cells of this type. Many of these cells have large vesicular nuclei with prominent nucleoli, and a nuclear diameter twice that of the nucleus of an ordinary endothelial cell. Some of the nuclei are lobed and some are double. The protoplasm is relatively scanty. These cells distinctly merit the designation of endothelial giant cells.

In addition to these changes there is, in the more central parts of the lymph-node, an increase in fibroblasts and a beginning fine sclerosis. Eosinophil cells are numerous throughout the lymph-nodes occurring singly and in groups. There is slight hyaline degeneration in places.

We have thus produced in the lymph-nodes of the monkey, a chronic lymphadenitis with atypical proliferation of the endothelial cells, a beginning proliferation of the stroma tissue, and a well-marked eosinophilic infiltration; also a periglandular sclerosis. Clinically, the animal's blood has shown an absence of polymorphonuclear leukocytosis after injection of the organism. An increasing percentage of mononuclear elements is found, particularly of the transitionals, an increase in eosinophils following a primary fall, and an early increase in basophils, all of which are characteristic of the early stages in Hodgkin's disease.[2] The blood-plates have also been numerous and large forms have been present.

With the picture in the lymph-nodes so similar to that of the early stage of Hodgkin's disease in the human being, and so different from an example of subacute lymphadenitis in the mesenteric lymph-nodes of a monkey which died of dysentery, and with the blood-picture showing the changes of human patients with the disease, we feel more assured of the etiologic relationship of the organism—which we have designated *Corynebacterium hodgkini*—to the disease.

Diseases Without a Morbid Anatomy.—Now diseases without a morbid anatomy are notoriously unsatisfactory to deal with, and are apt to be classed offhand as "functional," from which it is but a short step to speak of them as due to a neurosis.—Robert Hutchison in *Clin. Jour.*

WHO IS RESPONSIBLE?

THE POSITION OF CHEMISTRY IN MEDICAL EDUCATION

J. H. LONG, M.S., Sc.D.
Professor of Chemistry Northwestern University Medical School
CHICAGO

In an editorial in a comparatively recent issue of The Journal[1] the question is asked, Who is responsible for the lithia water fraud? This is but a special and relatively unimportant phase of an old problem, the responsibility for crude beliefs and medical frauds in general, but it seems a good text to point a lesson.

Faith in the superior efficiency of lithium salts as uric acid "solvents" dates back fifty years or more, and had its origin in the wrong interpretation of a simple chemical fact, but the absurdity of the claim has been many times shown, leaving quite out of consideration the well-known fact that most so-called lithia waters contain such minute traces of the element that the spectroscope is required for their detection. The scientific fallacy in the solvent doctrine was long since shown by physiologists studying the problem from the standpoint of the dissociation theory and the mass action laws. His and Paul,[2] especially, have contributed to the subject in their study of the solubility of uric acid and its salts, and their conclusions have passed into the general literature. Why are they and others not recognized? Who is responsible? The editorial in question answers that the responsibility rests with the medical profession, and refers the trouble back to the lack of proper instruction in pharmacology in the medical schools.

This explanation is only in a measure sufficient. Pharmacology has made wonderful advances in the last two decades and the methods of teaching the subject have correspondingly changed. I am inclined to think that much of this instruction is beyond the capacity of the student to follow, and this leads to the recognition of the real difficulty. The editorial truly says that in the understanding of the nature and action of drugs the student is often no better off than were the graduates of twenty or thirty years ago, but it does not go far enough in explaining the reason for this.

The medical sciences which have made the most notable advance in the last four decades are simply outgrowths of the new chemistry, or perhaps of the old chemistry plus a few new methods. This is emphatically true of pharmacology and the group of sciences based on bacteriology. I recall distinctly the first series of lectures given in the old Chicago Medical College (now Northwestern University Medical School) by Henry Gradle on the germ theory of disease. This was in 1882, and was probably the first formal presentation of the subject in the United States. The lectures were published in the following year and the book is still interesting reading. But how was it received then? Often with amusement, and it has taken medical men a long time to recognize that bacteriology is not, as far as their interests are concerned, a branch of morphology. Gradle and his "bugs" were often the subject of jokes, and the "bugs" were assumed to have about the same importance in the human body that other "bugs" have in injuring a tree by boring into it.

That bacteria are chemical rather than mechanical agents, and agents of great activity, is, of course, an elementary truth known to all real bacteriologists. In fact, their importance is almost solely from the chemical standpoint, and much of the new pathology has been reconstructed to accord with this view. The investigator knows all this, but how about the student? It must be confessed that the latter is often poorly equipped to follow the chemical side of bacteriology, which is the only side which offers any tangible explanation of the phenomena of importance to the physician. His chemical training is generally inadequate to enable him to get the full benefit from his studies in bacteriology.

If chemistry is fundamentally important in bacteriology it is no less so in pharmacology. The days of the morphologic study of crude drugs in the medical school (and the school of pharmacy, too) is rapidly passing, and fortunately so. Most of these things had little or no importance in medicine, but think of the time wasted on calamus and sarsaparilla, on cinchona bark and a hundred other things, the external characteristics of which gave no clue to their practical medicinal activity. The active principles of these drugs (when they have any value at all), or chemical synthetics, have taken their places; and here a knowledge of organic chemistry must help the student over some of his difficulties.

But just at this point the greatest mistake is sometimes made. How much of the instruction in chemistry of the medical school consists in learning formulas! I have known students to memorize the formulas for strychnin, quinin, morphin, albumin (!) and other bodies, thinking they were learning chemistry—students who at the same time were ignorant of the fundamental principles of combining proportions, mass action, valence or the simpler facts of organic synthesis.

As to what is the proper kind of chemistry for the medical school there have been various opinions, but I have maintained for years that, whatever the student may study in this science after entering the medical school, it is absolutely essential that he must be well grounded in elementary chemical theory, without which much of the work in organic chemistry, even, must remain meaningless. Without this foundation students are lame and remain helpless in all the subsequent work depending on chemistry. It is largely because of lack of acquaintance with the simpler principles that medical men often grapple with chemical problems which are quite beyond their power of solution. A man who is skilled in surgery is often able to duplicate a difficult operation from the knowledge gained by reading, but it does not follow that the same man can conduct a difficult chemical investigation in the same way. Yet such things are often attempted. There seems to be little appreciation of the length of time required for laying the chemical foundation.

A few years ago most of our leading medical schools adopted an entrance requirement which included elementary chemistry. Under this plan the work in chemistry in the medical school begins with organic, or, in some instances, with physiologic chemistry. This change was hailed as a great advance, but in practice it is somewhat disappointing. Students now bring to the medical school "credits" for chemistry, taken usually as an elective in some college. In theory this elective chemistry should be in advance of that usually given in the same field in the professional school, but as an actual fact this is often, perhaps usually, not the case. It is generally admitted that students in college do not work as hard as they did twenty or thirty years ago. College courses are now every-day affairs. I believe it is true that the average student carries away with him a smaller knowledge of chemistry than was the case with the boys who were obliged to take the work at the earlier period, and this in spite of the vastly improved equipment of our laboratories. The elective system may be partly responsible for the change. Easy electives are fine things to make up "units" or "semester" hours. The trouble is also in part due to the fact that many of our college teachers, perhaps naturally from a sort of necessity, are far more interested in their researches than they are in the hard work of elementary instruction. There is plenty of "professoring," but much less good teaching.

---

[1] May 17, 1913, p. 1544.

[2] His and Paul: Ztschr. f. physiol. Chem., 1900, xxxi, 1464; also Pharm. Ztg. at about the same date.

So unsatisfactory is the present scheme that some of our medical schools are finding it necessary to restore part of the instruction in elementary chemistry dropped when the higher requirements were inaugurated some years ago. I believe all schools will be forced to do it to secure a better preparation in the foundation principles. All students entering the medical school should be required to repeat in a recitation course part of their elementary chemistry and cover such topics as valence, the gas laws, general reactions, mass action, vapor density, cryoscopy and the solution of a great variety of problems.

It is of course urged that the student is already overworked and cannot take on more. There is much truth in this and he should not take on more, but he can drop something to take work which is fundamentally far more necessary and important. I think it can be said without question that a very appreciable part of the time spent on anatomy might well be spent on something else which in the evolution of the medical school will be far more in demand. The foundation disciplines for the study of medicine are anatomy and chemistry, and of these anatomy is by far the older. In fact, there were great anatomists five hundred years ago, and the historical position of anatomy in the medical school has been maintained down to the present time. I, of course, do not question the supreme importance of anatomy as pure science and I have the fullest appreciation of and admiration for the brilliant work of investigators in this line, but a large part of this morphologic science has about as much direct bearing on questions of internal medicine as has modern astronomy, which is an outgrowth, through centuries, of astrology, the sister science of anatomy in the early Italian schools. The time given to anatomy in our medical schools is relatively, and possibly absolutely, much in excess of what is necessary. The superior importance of this branch has been preached so long that many people have come to believe it. But the excessive time given to anatomy is undoubtedly one of the weak spots in the present system.

Courses in anatomy are always far more popular than courses in chemistry. (The dazzling allurements of surgery may be at the bottom of this.) The work is comparatively easy in the one case and difficult in the other. But as the supreme importance is commensurate with the difficulty, the science which is at the foundation of so many other medical sciences must be learned, even if it be necessary to reverse the present absurd time relations of the two disciplines in our first-year and second-year curriculums. In my early teaching experience I was more than once given to understand, and sometimes by students as well as by colleagues, that about all the chemistry a medical man needed was enough to make a sugar or an albumin test. It would seem so. Chemistry was for years but a tolerated study. The men who held this view of the place of chemistry in the medical course, however, were the men who made the continued success of the proprietary medicine vender possible. Men with this half knowledge or no knowledge of chemistry have always been an easy mark for the glib-tongued medicine factory agent who has something to sell.

I come back to the question, Who is responsible? I say that the medical school is responsible in neglecting a proper training in that science which is absolutely necessary to the understanding of pharmacology as well as bacteriology or physiology. There must be a return to a better study of pharmacology, to a study of the things which have value in the cure of disease, but this study must be preceded by a much profounder study of the real foundation science bearing on problems of internal medicine. The chemistry of the medical school should be thorough enough to leave no excuse for a therapeutic nihilism on the one hand, or for the prescribing of therapeutic impossibilities on the other.

VACCINATION WITH MIXED CULTURES FROM THE NOSE IN HAY-FEVER

CHARLES B. MORREY
Professor of Bacteriology, Ohio State University
COLUMBUS, OHIO

About four years ago I reported good results in treating ordinary colds with vaccines,[1] and I have successfully used the method as occasion arose since that time. This suggested a similar procedure with regard to hay-fever. Opportunity did not arise until the summers of 1911 and 1912, as detailed below. Since I am not in regular practice, only such persons as came voluntarily to be "experimented on" were available. Vaccines were prepared in the following manner:

Swabs similar to diphtheria swabs are rubbed over the nasal mucosa after the patient has first thoroughly blown the nose to remove dust and possible saphrophytes. The swabs were rubbed over the surface of large 19 mm. agar-slant tubes. Two slants are inoculated to avoid possible loss or lack of material. The tubes are incubated twenty-four hours. If little growth appears it is spread over the surface and incubated twenty-four hours longer. When, in either case, there is a heavy growth, this is rubbed off in normal salt solution, the growth from the two tubes is combined and the whole is diluted to 9 c.c. with normal saline. To this 1 c.c. of 5 per cent. phenol (carbolic acid) is added so that the material will contain 0.5 per cent. phenol when finished. The tubes are then heated in a water-bath at 60 C. (140 F.) for one hour to kill the organisms. The vaccine is now ready for use. The addition of the phenol before heating enables one to use lower temperatures for heating and thus diminishes the possibility of destroying the antigens in the organisms while still insuring the killing of the bacteria.

It will be noted below that the dosage is given in cubic centimeters or fractions instead of in numbers. I have been endeavoring for the past four years to find some method to determine the dose of a vaccine and have come to the conclusion that this is possible only from the results of the first vaccination. Organisms vary so much in virulence and patients so much in tolerance that dosage is a purely individual matter in each instance. Consequently vaccines are prepared of approximately the same strength and an amount is given the patient which he can apparently tolerate without inconvenience. Measurement in fractions of a cubic centimeter is the ordinary way of regulating the dose after the first in practice in any event, that is, when the vaccines are standardized as to numbers.

---

[1] Vaccine Therapy of Colds, Correspondence, The Journal A. M. A., May 1, 1909, p. 1439.

Case 1.—The patient, a university graduate and a high-school teacher, aged 23, had had "hay-fever" regularly the past five or six years. It began usually about the end of July, and lasted until two or three weeks after a heavy frost. July 30, 1911, 1.6 c.c. of vaccine were injected. No local or constitutional effect from the injection was noted. August 6 the patient reported that he *had not sneezed since the vaccination, and nasal discharge had been practically absent;* 1 c.c. of the original vaccine was injected as a second dose. During the following week the patient went on duty from 6 a. m. until 11 a. m. daily, as ticket-seller at the local driving park. The air in the ticket-booth was foul from its incidental use as a privy, and the food furnished was so poor that it could not be eaten, so that the patient said he "lived on watermelon and buttermilk." He had attacks of sneezing each morning, though little during the day. August 14, only 0.2 c.c. of a new vaccine was injected but with no noticeable effect. August 18, 0.6 c.c. of the same vaccine used which had a slight effect. August 22, 1 c.c. was injected by the patient's uncle, a physician, which gave relief for twenty-four hours only. August 28, 1 c.c. of a new vaccine was given and the patient removed to a city on Lake Erie to begin high-school work. He was convinced that he had been better than for any of the past five years. He reported in the fall of 1912 that for the past summer (not under treatment) his attacks had been scarcely one third as bad as normal.

Case 2.—The patient, a university professor, had typical "hay-fever" for the past five or six years. It began usually about the middle of August, though this year he had been sneezing since July 1. Aug. 10, 1911, 1.3 c.c. of vaccine was injected. The dose was too large, and the reaction was severe and kept the patient in bed until the next afternoon. He did not sneeze once until the 13th. August 14, he reported that he had sneezed five or six times on the 13th and 14th, but "nose had not run since the 10th." August 16, a second vaccine was made and only 0.3 c.c. injected; the effect was only slight, and 0.4 c.c. was given August 18. From this time on the patient had so little trouble that he did not consider further vaccination necessary. He "enjoyed being in the dust where buildings were being razed [he is an architect], and sitting among the vines on his porch," which had been impossible before owing to the paroxysms. During the summer of 1912, he did not suffer enough from hay-fever to believe it worth while to be vaccinated.

Case 3.—The patient, an agent, had hay-fever for twelve years. For the past five years he had gone to Duluth to remain from August to December to escape, though in 1911 he had a slight attack while there. Aug. 12, 1912, 0.7 c.c. was given with practically no results. August 16, 1.2 c.c. was given with practically no results up to August 27, when 1.2 c.c. of a new vaccine was given. August 31, the patient reported a good effect to date and little sneezing. September 12, 1 c.c. was given. The patient reported no hay-fever since the last vaccine. No further vaccination was given. October 12, he reported that he had no more hay-fever.

Case 4.—The patient, a lawyer, had had hay-fever for eighteen years, and asthma the past few years with it. Aug. 13, 1912, 0.8 c.c. was given with no reaction, and no sneezing up to August 16, when the second dose, 1.2 c.c., was given. August 30, the patient reported great relief the past two weeks, with practically no hay-fever. There was no effect on the asthma. August 31, 1 c.c. of new vaccine was given and none since, as he has had no hay-fever.

Case 5.—The patient, a business man, had had hay-fever for years. Aug. 25, 1912, 0.4 c.c., a small preliminary dose, was given, with slight effect. August 29, 1 + c.c. was given. The reaction was severe, so that the patient felt "out of sorts" for about two days; but the nose cleared up and all symptoms disappeared, and the patient had no further hay-fever, as he reported in November.

Case 6.—The patient, a lumber-dealer, had hay-fever for five or six years. Aug. 31, 1912, 1 c.c. was given and the patient left the city. Vaccine was sent to his physician and he administered the second dose, September 6. I have only the patient's statements as to the effects. "The first vaccination (Saturday, August 31) was followed by 2 degrees of fever and a chill that evening, a slight one the following evening. Felt like taking the grip. Feverish Sunday, but better Monday. Next three days felt about like one with a cold. Second vaccination followed by much the same effects, but not so pronounced. About like one with a cold the next week, sneezed a little and some nasal discharge, but not the 'hot kind.' Felt better than since had hay-fever, about six years."

Case 7.—The patient, a bookseller, had had hay-fever for thirty-three years. Sept. 3, 1912, 1.2 c.c. of vaccine was given. The patient reported that the nose had dried by the following day and his "necessary handkerchiefs had dropped from about twelve per day to none" for hay-fever purposes. September 7, the second and final vaccination was given, as the patient had no further attacks.

Case 8.—The patient, a Cornell University student, aged 21, had had hay-fever during the past twelve years, and asthma with it the past three years. It lasts from about the second week in August to the end of September. Sept. 11, 1912, the first vaccine was given, and material was sent to the patient, who was given a second injection, September 17. A letter from the patient dated the 17th reported the "head fairly clear, and felt much better," but no further information was received from him or his physician.

The cases are few, but are certainly interesting, especially Cases 3, 4, 5 and 7, in which the patients were under my personal observation in 1912, as were the patients in Cases 1 and 2 in 1911. The satisfying results of these two led to the continuation of the work in 1912, and the experimental vaccination was an excellent guide to procedure. It appears of promise, also, that these two were much better in 1912, though they took no treatment.

I have made no attempt to discover any "specific germ" of hay-fever and do not believe that it exists. The theory on which the work was based was the strengthening of the nasal mucosa, so that the irritants, whatever they are, would be without effect.

THE CEREBRAL FORM OF PERNICIOUS MALARIA *

J. F. PATTERSON, M.D.
NEWBERN, N. C.

Cerebral malaria is a form of pernicious malaria, the etiologic factor being the *estivo-autumnal parasite,* that is, the *crescent-forming hemameba.* The fevers caused by the estivo-autumnal parasite are characterized by some main group of symptoms depending on which organ of the body participates mostly in the infection, in other words, the organ that is affected; for the malarial parasite of this type can attack any organ in the body and give rise to symptoms characteristic of involvement of that particular organ; for example, if the liver is involved we have bilious symptoms, if the brain, cerebral symptoms, and so on. This is the most important point to remember, for we can readily see that pernicious malaria may simulate any disease and lends emphasis to the necessity of a blood examination for the malarial parasite in all cases in which the diagnosis is obscure.

---

* Chairman's article before the Section of Practice of Medicine at the 1913 Session of the Medical Society of the State of North Carolina, held at Morehead City, N. C., June, 1913.

The symptomatology of cerebral malaria is most varied and complex; the disease may simulate any organic disease of the brain and, in some cases, the resemblance is so exact that a proper diagnosis rests on the blood examination. As a rule the clinical picture is dominated by a well-defined group of symptoms and on this basis we may divide cerebral malaria into the following types: (1) comatose; (2) motor irritative; (3) motor depressive.

Coma is a symptom of all the types, the associated symptoms varying with the different types. As a rule cerebral malaria does not occur with the first paroxysm but is preceded by several. Its onset is always sudden, occurring with startling swiftness.

COMATOSE TYPE

This is by far the most frequent. The coma is the cardinal symptom; it may be of varying duration and intensity; it may last a few hours or several days. As a rule it is quite pronounced, there being no response to stimulation. A characteristic of the coma is fibrillary twitching of the muscles of the extremities; the eyes are closed, the lids being resistant to elevation, eyeballs rotated upward, the pupils equal, usually dilated but sometimes contracted. The pulse may be either fast or slow, respirations as a rule being stertorous but in some cases shallow and rapid. The temperature is high, varying between 103 F. and 105 F. The coma usually subsides with diaphoresis, but in some cases it does not; instead being more pronounced until death, which usually results from pulmonary edema.

The following case well illustrates the comatose type:

Case 1.—Mrs. X, aged 53, was seen at 7 p. m. on the night of October 9. She was in a profound coma, respirations 25 and stertorous, pulse 140 and weak, skin ashy in color and dry, eyes closed, the balls were rotated upward and moving slightly, pupils equal, slightly dilated and reacting to light; temperature by rectum was 103 F. The coma was profound, the patient not responding to any form of stimulation.

The following history was obtained from relatives:

For the past six weeks she had been ill, first suffering from gall-stones, and for the past two weeks had been treated by an osteopath, a diagnosis of nephritis having been made by him. On close questioning it was learned that on alternating days she had been having a feeling of coolness followed by nausea, vomiting and an elevation of temperature. On diaphoresis the symptoms subsided, undoubtedly being malarial paroxysms which were unrecognized. At noon the day that I was called to see her, she had another of these paroxysms, soon after became unconscious, the coma being quite profound when I saw her at 7 p. m. A specimen of urine obtained by catheterization showed the findings of a febrile albuminuria, there being a slight amount of albumin and no casts. A blood examination revealed numerous malarial parasites of the estivo-autumnal form, most of them being extracorpuscular.

At 5 p. m. she was given hypodermically 12 grains of quinin and urea hydrochlorid, also 1/40 grain of strychnin; at 11 p. m. 6 grains more of quinin hypodermically was given. At midnight she showed signs of regaining consciousness; at 1 a. m. she had completely aroused and the convalescence from then on was uneventful, there being no return of symptoms. Her treatment consisted of 6 grains of quinin hypodermically every three hours for seventy-two hours, 20 grains of calomel during the first twenty-four hours; the remainder of the treatment consisting of tonics.

This case was interesting because it closely resembled uremia, the differentiation being based on (1) urinary findings, (2) blood examination, (3) history of previous malarial paroxysm, (4) pupils being dilated.

MOTOR IRRITATIVE TYPE

While the motor symptoms predominate, coma is also a symptom. The motor symptoms may vary from twitching of the muscles to clonic convulsions and may simulate uremia, hysteria or tetanus. The following case so closely resembles hysteria that at first that diagnosis was made:

Case 2.—Mrs. B.'s housegirl, a negress aged about 21, was found unconscious in the living-room where a few minutes before she had gone to do housework. When I arrived the girl was lying on the floor profoundly unconscious, muscles rigid, eyes closed, lids resistant to opening, pupils dilated but responsive; the pulse was 120. The least stimulation of the skin caused clonic convulsions, each convulsion lasting from five to twenty seconds. No history was obtainable and the patient was removed to the hospital. It was impossible to take temperature by mouth or rectum because of the clonic and tonic spasms; for the same reason attempts at catheterization were a failure. Morphin ¼ grain was given hypodermically and during the night ½ grain more was given because of the continuance of the motor symptoms. The condition remained the same until the following afternoon at 5 p. m., when the patient became somewhat relaxed. Her temperature was then taken by rectum and found to be 102 2/5 F., pulse 140, weak and intermittent; a blood examination revealed the estivo-autumnal parasite, and the condition was now recognized as cerebral malaria. At 6 p. m. the patient was given 12 grains of quinin hypodermically and thereafter 9 grains every four hours; 4 drops of croton oil also was given. The following morning she aroused from the coma, the temperature was normal, and on being questioned she stated that she had been having chills for the previous two weeks. She made a rapid and uneventful recovery.

MOTOR DEPRESSIVE TYPE

This form may present paralysis of the monoplegic, paraplegic or hemiplegic type, the paralysis usually commences and subsides with the paroxysm. This form of cerebral malaria is extremely rare and very few cases have been reported. Landouzy states that he has only been able to collect twelve cases in all the literature. The following case is of the hemiplegic type, the hemiplegia lasting for forty-eight hours:

Case 3.—Mrs. P., aged 65, an unusually well-preserved and active woman, had a chill on June 12 and another on June 14. I saw her on this day. She responded to treatment and was afebrile on the 15th, but the next day at noon she had her third chill. At 4 p. m., when I saw her, the temperature was 103 F., pulse 90 and full. She was confused, her speech was thick and slurring, and by 8 p. m. she was profoundly comatose. There was complete flaccid paralysis of the right side of face and body, knee-jerk on the right side being exaggerated, breathing stertorous and 18 per minute, pulse bounding and 74. The eyes were closed, pupils contracted, eyeballs deviated toward the left, rectal temperature was 104 1/5 F. A blood examination revealed malaria plasmodia. Quinin 6 grains was given hypodermically every four hours. The following day the condition was practically the same, but by night the patient had responded slightly from coma. Her paralysis gradually subsided and forty-eight hours after onset it had completely disappeared. The quinin was continued hypodermically for four days. Mental confusion remained for four weeks. This was a most interesting case and the diagnosis rested between cerebral malaria and cerebral hemorrhage due to rupture of a vessel as a result of the elevation of blood-pressure produced by the paroxysm. The rapid response to quinin and complete disappearance of the hemiplegia in forty-eight hours, there being absolutely no sequelae, show conclusively that the case was cerebral malaria.

In the majority of cases all mental symptoms disappear with the subsidence of the paroxysm; but in a few, symptoms of confusion remain for some time. In Case 3 symptoms of confusion remained for four weeks. At the last meeting of the Southern Medical Association, Dr. L. A. Green of Jacksonville, Fla., stated that the records of the State Hospital of Florida show a number of cases of patients admitted as insane whose condition was due to cerebral malaria and responded to quinin medication. This I readily believe, for I was so fortunate as to see in consultation with Dr. R. D. V. Jones of Newbern, N. C., a case of cerebral malaria in which symptoms of confusion lasted for over two months. This patient had hallucinations of sight and hearing and illusions of the same senses and at times was in a state of grandeur. So it should be recognized in malarial districts that cerebral malaria is a possible etiologic factor in all acute mental conditions.

CONCLUSIONS

1. Cerebral malaria may assume the form of any brain disease.
2. It is practically never due to the first paroxysm but to succeeding ones and by energetic treatment of the first paroxysm it may be prevented.
3. The specific action of quinin hypodermically and that the drug must be given for effect—the dose usually being 9 to 12 grains every four hours.
4. Cerebral malaria is a frequent disease in malarial districts.

CASE OF STAB WOUND OF THE HEART, OPERATION AND RECOVERY

SAMUEL BRADBURY, M.D.
Assistant Attending Physician, New York City Hospital
NEW YORK

An Italian woman, aged 44, was brought to the Pennsylvania hospital at noon on April 18, 1909. She had been stabbed in the chest about ten minutes previously. Examined immediately on admission. She was unconscious, very pale, the skin was moist and cold, there was slight dyspnea and no pulse could be felt at the wrist. A wound 1.5 cm. long was present over the second left intercostal space about 5 cm. from the sternal edge. The heart sounds could be heard faintly, were rapid and slightly irregular, but no adventitious sound was heard. The breasts were lactating and full. The outline of cardiac dulness was not determined. Ether, 25 minims, then 1/20 grain of strychnin were given hypodermatically at once, and a very feeble radial pulse could then be palpated, rapid and slightly irregular. The diagnosis was wound of the heart.

Operation was started at 12:50 p. m. A curved incision was made about the inner border of the breast from the second to the fifth rib, and skin, breast and muscles reflected outward. The wound was then seen to enter the thorax through the fourth left intercostal space about 3 cm. from the edge of the sternum. The third and fourth ribs were divided at the costochondral junction and at the chondrosternal articulation and were turned inwardly over the sternum. The pleural cavity was opened freely by this procedure and it was noted that it contained only a small amount of blood. The internal mammary artery was ligated above. A wound 5 cm. long in the precordial fat and pericardium was enlarged by tearing, releasing a quantity of blood and blood-clots which gushed out under considerable tension. The pulse improved immediately and was then noted to be 80, regular and fairly full. The heart wound was about 3 cm. long, crossing the anterior interventricular groove diagonally from above and to the left, to below and to the right about midway between the apex of the heart and the auriculoventricular groove, a little more than half of the wound lying over the right ventricle. A column of dark blood spurted out with each systole. Six or seven linen thread sutures closed the wound, one of them catching the cut left descending coronary artery. Some clots lying behind the heart were scooped out with the fingers, and as there was no further bleeding the pericardium was closed, using a continuous catgut suture. A rubber drainage-tube was inserted through the left ninth intercostal space into the thoracic cavity and sutured in place. About a liter of blood was drained out, most of it having come from the pericardium. The ribs and intercostal muscles were sutured with catgut, the pectoral muscles with catgut and the skin with silkworm-gut. A small gauze drain was inserted into the outer stab wound. The operation was finished at 1:55 p. m.

The anesthetic was ether, 2½ ounces by the open drop method. It was started at 12:45 and stopped at 1:45 p. m. The patient was then given ¼ grain morphin sulphate, 1/150 grain atropin sulphate hypodermatically, and 8 ounces of normal saline solution slowly by rectum.

The blood examined during operation showed hemoglobin 75 per cent., red blood-cells 4,842,000 and leukocytes 19,400.

The patient was quite comfortable, with a temperature of 100 and a pulse of about 100 until the fourth day. Then there was a sudden increase in the pulse-rate to 140, great restlessness, some dyspnea, a marked engorgement of the cervical veins and a dilatation of the left pupil. These symptoms were thought to be due to a pericardial effusion. The fifth day the venous engorgement and dyspnea were much lessened, and on the sixth day a large amount of fluid was removed from the chest after the drainage tube had been removed, the sinus opened up and the tube replaced. Until the fourteenth day the breasts required stupes and massage. On the thirty-second day, the second day in a chair, the patient had a sudden attack of cyanosis and marked dyspnea, which lasted only five or ten minutes, and was relieved as soon as she lay down. This attack may have been due to an embolus, but there were no other symptoms. On the forty-second day a consolidation developed in the upper lobe of the left lung. She ran a high remittent temperature for five days, then it fell to normal and the cough and all the signs in the lung cleared up.

She was discharged on the ninetieth day, easily able to get around by herself. Her pulse-rate was 88, heart was in its normal position, and the heart sounds were of normal character.

A representative of the Pennsylvania Hospital Social Service Department visited her in April of this year and reports that she looks perfectly well, and is doing her own housework. She has a little dyspnea on climbing stairs, but never any cardiac pain or edema. Her pulse is 64, regular and of good volume.

There are two points of interest in this case. First was the marked heart tamponage with the immediate and marked improvement in the rate and character of the pulse when the pericardium was opened. The second interesting feature was the division and ligation of the left descending coronary artery. In the several lists of cases[1, 2] published, this complication is noted in six; this case is the seventh. The cases are those of Cappelen, Pagenstecher, Vince, Foramitti, F. T. Stewart's first case, and one of those in the series of twenty-one reported by E. Hesse. Three of the seven patients died within three or four days of operation, four have recovered. Hesse's patient was well eighteen months after operation, the woman reported in this paper is well four years after operation. Stewart's patient worked for five years as a janitor, handling heavy boxes, and finally died of pulmonary tuberculosis. The detailed necropsy report is given in his recent paper,[3] and showed quite an exten-

sive myocarditis and the wall of the ventricle was very thin at one place.

These cases would seem to be of considerable interest in view of all the recent clinical and experimental work that has been done to prove that the coronary arteries are not end arteries, as was at one time supposed.

A PRELIMINARY NOTE ON SPIROCHAETA PALLIDA AND LIVING TISSUE-CELLS IN VITRO *

EDNA STEINHARDT, M.D.
NEW YORK

Having successfully applied Harrison's method of tissue growing *in vitro* to the cultivation of the virus of vaccinia,[1] we have here tried the same method with the *Spirochaeta pallida*. In the present experiment the organisms used were from a culture obtained from Dr. Noguchi. He has kept it growing for some length of time and states that it has lost most of its virulence.

Hanging-drop preparations were made of small pieces of the testes of the rabbits inoculated with spirochetes, to which rabbit plasma was added. The preparations were incubated at 37 C. (98.0 F.). Before incubation preparations examined in the dark field did not show spirochetes nor did those examined during the first few days of incubation. Evidently very few spirochetes were inoculated. The cells of the testes, however, showed a good growth.

After incubation for twenty-five days examination with the dark field showed many organisms. These were extremely motile. Short forms found strongly suggested multiplication of the organism and not merely a survival of the original inoculation. The early negative examinations would also suggest a multiplication.

The organisms were inoculated into the testes of a rabbit and the virulence will be reported later. It seems possible by this method of growing avirulent cultures with living cells and transferring them to fresh cells to restore their pathogenicity. This would be in line with the increase of virulence found in bacteria submitted to the action of immune serum. Further experiments are now being made in this direction and also on the direct inoculation of spirochetes from syphilitic lesions.

Research Laboratory, East Sixteenth Street.

THE PREPARATION OF ALBUMIN MILK IN THE HOME

Jules M. Brady, B.S., M.D., St. Louis
Assistant Professor of the Diseases of Children, St. Louis University School of Medicine

The value of albumin milk as a therapeutic agent in the nutritional disturbances of infancy has been fully established. The difficulty of its preparation has curtailed its use very much.

The original directions for its preparation called for a quart of sweet milk brought to the boiling point, allowed to cool to 100 F. and then curdled with a tablespoonful of essence of pepsin. The whey is drained off and the curds suspended in a muslin bag for two hours. The curds are then passed through a hair sieve by gentle pressure with a large spoon or potato masher adding at the same time a pint of fat-free buttermilk. Boiled cool water is then added to bring the whole up to one quart. The preparation is then ready for the addition of from 1 to 5 per cent. of maltose and dextrin.

The main difficulty is in getting the curds to pass through the sieve. In our institution we prepare from 10 to 15 quarts a day. This formerly was a huge task and would consume anywhere from one-half to two hours. And still the product could not be considered ideal. As the result of mashing the curds through the sieve, the fat separates out in the form of butter and your infant is robbed of many calories that he ought to be getting. Recently some have the curds prepared from skim-milk instead of whole-milk. This in some instances might be desirable but in a large group of infants we desire the mixture to contain fat.

METHOD

At St. Ann's Infant Asylum we have found a method of reducing very much the time and labor. The following are the directions in detail:

1. Bring a quart of sweet whole-milk to the boiling point; raw-milk is not used as its curd is much tougher.
2. Cool to 100 F.
3. Add one tablespoonful essence of pepsin and allow to curdle.
4. Pour off the whey and suspend curds in muslin bag two hours.
5. Stand bag containing curds in 8 ounces boiled cool water for one hour. This is very important and is the secret to the success we have had in the preparation of this food.
6. Remove the bag from the water, allow as much water to drip as will and place curds in sieve.
7. Add pint of fat-free buttermilk to sieve containing curds, and stir; it will be found that the curds will pass through in two to three minutes, which must be repeated three or four times.
8. Turn the bag inside out and return to the 8 ounces of water so as to obtain all the curd.
9. Pour in the sieve the 8 ounces of water which was used to soak the curds.
10. Add enough water so that the whole measures a quart.
11. Add the percentage of maltose-dextrin desired and put on ice.

We are able to prepare 10 quarts of this food after the curds have drained and soaked in less than ten minutes with the minimum separation of the fat.

1467 Union Avenue.

A CASE OF ANEURYSM OF AORTA RUPTURING INTO THE VENA CAVA

Orlando H. Petty, M.D., Philadelphia
Instructor in Medicine, Jefferson Medical College; Pathologist and Assistant Physician to St. Timothy's Hospital

History.—D. S., bachelor, aged 70, 6 feet in height, weight 220 pounds, with negative family history, denying syphilis, had never been ill until several months previous to the time I first saw him, Feb. 21, 1911. During those months he became short of breath and had pain in the front part of his chest when climbing the hill to his home and had been treated for asthma. When I first saw him he had severe pains in his chest and was so short of breath that he could not walk across his room. He was chiefly anxious because his eyelids, face and hands were swollen, and his tongue seemed thick.

Examination.—Patient was dyspneic, his face, neck, arms and upper part of his chest swollen and cyanosed, with edema over the exposed bony surfaces. The external jugular veins were full, but no pulsation could be detected. Superficial veins of upper chest were plainly visible. The rest of the body was neither edematous nor cyanotic. There were no visible pulsations. There were distinct diastolic shock over great vessels at base of heart, and heart dulness on the right at the right edge of the sternum and on the left at the midclavicular line in the second interspace and 2 cm. outside of midclavicular line at the fourth interspace. Apex beat was at sixth interspace 2 cm. outside of midclavicular line. There was also a distinct dulness from third rib at right sternal margin extending almost to right midclavicular line, thence upward to second rib, and then slightly upward and inward, crossing first interspace at right sternal border and extending entire width of sternum. No other pathologic dulness was discovered over chest. Liver was enlarged and tender. There was no adenitis.

---

* From the Research Laboratory, Department of Health, New York.

[1] Steinhardt, Israeli, and Lambert: Jour. Infect. Dis., 1913, xiii, 294.

A to-and-fro systolic murmur was heard over precardia, also over dull area to right of sternum, being louder at this point. Heart sounds were weak; no valvular lesions could be definitely diagnosed. Systolic pressure was 136, diastolic 110, the same in right and left arms.

February 22: Patient complains of fulness of throat, and tongue seemed thicker. The swelling and cyanosis noted the day before were more marked.

A prominent clinician, who had seen two similar cases, one a case reported by Pepper and Griffith, the other his own reported in 1906, saw this case with me and agreed with my diagnosis of aneurysm of the arch, rupturing into the superior vena cava. There were no marked changes in the patient's condition until February 28, when the physical signs had changed and the distressing symptoms were greatly diminished. The dull area was much smaller and the to-and-fro murmur had disappeared. Within the next two or three days the cyanosis and edema also disappeared, which suggested the need of a revised diagnosis. Because of the previous classical symptoms, however, I was unwilling to give up my diagnosis of this rare condition, regarding the changed signs and symptoms as being due to closure of the perforation by the formation of a blood-clot.

The patient died March 8, 1911, just fifteen days after I first saw him, and I received permission to open the chest. This revealed a fusiform aneurysm involving the ascending and horizontal parts of the aorta, the maximum diameter being at the junction of these two portions. This diameter is 7 cm. The aneurysm terminated immediately beyond the origin of the left subclavian.

The inner surface of the wall of the aneurysm was in general fairly smooth, although almost uniformly covered by atheromatous plaques, only a part of which were calcareous, a few of the latter form slight elevations on the wall.

At the posterior portion of the aneurysm where the diameter is the greatest, there was a secondary saccular dilatation. This was 3 cm. in diameter, almost circular in outline, and was 2 cm. in greatest depth. This sac was filled with a laminated blood-clot. The bulging of this secondary sac was directly in the line of the superior vena cava, which was carried distinctly backward and to the right at this point.

Slightly to the right and center of this sac was a nearly circular perforation, 5 by 6 mm. in extent, into the superior cava. Viewed from the caval surface this opening was near the margin of a slightly elevated and thickened grayish-yellow area 1.2 cm. in diameter. The point of perforation was directly on a level with the opening of the vena azygos major and 1 cm. from it. The perforation was 3 cm. from the junction of the right subclavian and innominate veins and 7 cm. from the aortic valves. This opening, which formed communication between the aorta and the cava, was completely closed by the blood-clot that filled the secondary aneurysmal dilatation as described before.

The necropsy findings therefore substantiated the diagnosis of aneurysm of the aorta with rupture into the superior vena cava. The changes in physical signs and symptoms six days before death were also fully explained by the blood-clot which closed the perforation.

6215 Ridge Avenue.

Tuberculosis of the Kidney.—It is now generally admitted that tuberculosis starts by attacking one kidney, that spontaneous cure of a tuberculous kidney does not occur, and that the only hope of saving the life of the patient rests on an early recognition of the disease and a speedy removal of the infected organ.—David Newman, M.D., *Glasgow Med. Jour.*

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

STREPTOCOCCUS VACCINE.—See N. N. R., 1913, p. 226.

Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Antistreptococcic Vaccine (Scarlatina Prophylactic).—This product is marketed in three ampules containing respectively 250 million, 500 million and 1 billion killed streptococci.

Strepto-Bacterin (Scarlatina Bacterin) Polyvalent.—This product is marketed in six ampules each containing 100 million killed streptococci.

SILK PEPTONE "HOECHST."—Silk Peptone "Hoechst" is a preparation of peptone derived from silk and standardized to a nearly uniform optical rotatory power.

Silk peptone is prepared from silk waste as follows:

The material is dried at 100 C. for forty-eight hours and then treated with from 3 to 5 times its weight of 70 per cent. sulphuric acid and allowed to stand for four days. It is then diluted with ten times its volume of water cooled by ice. The sulphuric acid is neutralized with barium hydroxid and filtered through charcoal. The residue on the filter is repeatedly stirred with warm water (25 C.) and decanted, or it may be washed thoroughly with boiling water.

The filtrates are concentrated at a temperature not above 40 C. The thick liquid, which must be free from barium and sulphuric acid, is poured with constant stirring into absolute alcohol which precipitates the silk peptone. Care must be taken that the alcohol is renewed at intervals so as to maintain the proper strength for precipitation. The yield with careful technic amounts to 20 to 30 per cent. of the products used.

Silk peptone is a white or yellowish powder, easily soluble in water, but not hygroscopic. The aqueous solution has a slight acid or amphoteric reaction. Its concentrated solutions are practically colorless and thus adapted for use in optical methods. It also possesses a high content of tyrosin.

Actions, Uses and Dosage.—Silk Peptone "Hoechst" is not employed therapeutically. It is used for the detection of peptolytic ferments either by changes in optical activity or by the precipitation of tyrosin. It is also valuable as an addition to culture mediums for the differentiation of bacteria.

For use silk peptone is dissolved in water, or in testing stomach conditions it may be dissolved in the filtered contents. The solutions must be clear and entirely neutral; if acid, they must be neutralized with sodium bicarbonate or magnesium oxide. If it is desired to keep a solution for some time, it should be covered with a layer of toluene.

(1) *To Test for Peptolytic Ferments in the Tissues.*—A small piece of the organ to be examined is introduced into a solution of silk peptone (25 per cent.), covered with a little toluene, and placed in the incubator. After a short time, if peptolytic ferments are present, a more or less abundant separation of tyrosin crystals takes place. In a similar way liquids may be tested for peptolytic ferments by mixing the clear filtrates with the silk peptone solution.

(2) *To Examine Stomach Contents for Peptolytic Ferments.*—5 c.c. of the stomach contents should be neutralized with magnesium oxide and filtered. To the filtrate 0.2 gm. of silk peptone are added. The mixture is incubated and examined at intervals of thirty minutes for a possible separation of crystals (tyrosin). If this occurs, the presence of peptolytic ferments may be assumed; to confirm this assumption a test for tyrosin should be applied.

(3) *The Optical Method.*—The material to be examined should receive the proper preliminary treatment, mixed with a solution of silk peptone and placed in a polarimeter tube, covered with some toluene, and the optical rotation immediately determined. This is repeated at intervals of several hours f [illegible] t two da[illegible] the mixture being placed mean-

while in the incubator. If a change in optical rotation occurs, while the control solution retains the original degree of rotation, the presence of peptolytic ferments may be assumed.

Manufactured by Farbwerke vorm. Meister Lucius & Bruening, Hoechst a.M., Germany (Farbwerke-Hoechst Co., New York). No U. S. patent or trademark.

ORAL CLEANLINESS

(Concluded from page 1719)

MOUTH-WASHES AND GARGLES

There are perhaps fifty mouth-washes on the market. They are all more or less similar in their composition, more or less multiple in their constituency, and more or less expensive, and represent more or less enormous profits to their owners. A number of pharmacopeial and National Formulary preparations have been developed to meet the need for mouth-washes and also to imitate some of the proprietary preparations. A few of these formulas will be considered to see what is the need for so many ingredients and what is really the value of the various preparations.

Such polypharmacy as this is absolute nonsense. As in many pharmaceutical preparations, the value of the really useful ingredients is obscured by the useless shrubbery and weeds which surround them. A dash of this and a dash of that in these mouth-washes or gargles is simply playing to the galleries. Although it may seem a waste of time to criticize these simple and more or less harmless preparations, still, with the now recognized importance of oral cleanliness, it is as necessary to analyze our methods of procuring oral cleanliness as it is to note the efficiency of fumigation, and much of the latter is a delusion and a snare.

The following are a few of the mouth-washes most used:

LIQUOR ANTISEPTICUS ALKALINUS, N. F.

Potassium bicarbonate	3.2
Sodium benzoate	3.2
Sodium borate	0.8
Thymol	.02
Eucalyptol	.02
Oil of peppermint	.02
Oil of wintergreen	.04
Tincture cudbear	1.6
Alcohol	6.0
Glycerin	25.0
Talcum	1.0
Water	ad 100 0

This preparation is very similar to the much-advertised Glycothymoline. The proprietary preparation of Borolyptol is quite similar to this alkaline antiseptic solution, with the coloring matter omitted, and contains 8 per cent. of alcohol.

LIQUOR ANTISEPTICUS, U. S. P.

Boric acid	2 0
Benzoic acid	0.1
Thymol	0.1
Eucalyptol	.025
Oil of peppermint	.05
Oil of wintergreen	.025
Oil of thyme	.01
Alcohol	25 0
Talcum	2.0
Water	ad 100.0

This preparation is very similar to the long-advertised Listerine. The proprietary Euthymol is also very similar.

The Liquor Antisepticus can be made for about ten cents a pint and the Liquor Antisepticus Alkalinus for about five cents a pint. The profit on similar proprietary preparations may be readily estimated.

LIQUOR SODII BORATIS COMPOSITUS, N. F.

(Dobell's Solution)

Sodium borate	1.5
Sodium bicarbonate	1.5
Phenol (carbolic acid)	0.3
Glycerin	3.5
Water	ad 100.0

The much-used so-called Seiler's tablets may be offered in several formulas. The following is one of them:

Sodium bicarbonate	
Sodium borate	
Sodium chlorid	āā ℥ 84
Sodium benzoate	
Sodium salicylate	āā ℥ 3½
Eucalyptol	
Thymol	āā ℥ 3½
Oil of wintergreen	℥ 1

Of this mixture each tablet should represent 15 grains.

The proprietary preparation of Alkalol is believed to contain the following ingredients:

Boric acid	0.8
Sodium borate	2.5
Sodium bicarbonate	0 8
Sodium chlorid	0.8
Eucalyptol	.06
Oil of wintergreen	.06
Oil of spearmint	.04
Oil of thyme	.02
Camphor water	.4
Alcohol	5.0
Burnt sugar	9.8
Water	ad 100.0

The proprietary Formolid has about the following formula:

Acetanilid	2 grains	to the ounce
Alcohol	15	per cent.
Boric acid	2	per cent.
Boroglycerid	1	per cent.
Sodium benzoate	0.5	per cent.
Formaldehyd	0.25	per cent.

Eucalyptol, thymol, menthol, oil of wintergreen.

Mucol powder is about as follows:

Sodium borate	12.0
Sodium chlorid	12.0
Thymol	0.4
Camphor	0.2
Oil of wintergreen	0.125
Eucalyptol	0.2

Kolynos is stated to contain the following:

Alcohol	21.8
Calcium carbonate	20.5
Soap	26 0
Saccharin	.50
Benzoic acid	2.50
Oil of mint	2.25
Thymol	.25
Oil of eucalyptus	2.0
Glycerin	24.2

Reference to the foregoing formulas shows that the aim is more or less antiseptic, and that the preparations are more or less alkaline and demulcent, with more or less modification of the taste, and some coloring matters of unimportance. The antiseptics used are alcohol, glycerin, salicylic acid, boric acid, sodium borate, benzoic acid, thymol and, in the one instance of Dobell's solution, phenol. Of course there can be no question of the antiseptic action of phenol in a 0.3 per cent. solution.

The antiseptic action of alcohol and any possible astringent action is more or less negligible, except in the Antiseptic Solution and the preparations that are similar to it, and in the Kolynos, in which the amount is from 21 to 25 per cent.

The only preparation mentioned containing salicylic acid is Seiler's tablet, which contains sodium salicylate in very small amount.

The antiseptic and demulcent action of glycerin varies of course entirely with its percentage.

All of these preparations contain boric acid or sodium borate. The action of these drugs in the strength used is very mildly antiseptic, and they are very weak antiseptics even when undiluted. They are more or less soothing to mucous membranes, and more or less stimulant to the flow of mucus.

Several of the preparations contain sodium chlorid. This of course is simply soothing to mucous membranes in the solution presented.

Sodium bicarbonate is alkaline and soothing and promotes mucous secretions.

Benzoic acid, or benzoate of sodium, appears in some of them, and is very mildly antiseptic and has a pleasant odor.

Thymol is an antiseptic, but not of much value in the strength presented, and is disagreeable.

Eucalyptol may be mildly antiseptic, but has no special value as a mouth-wash.

The other ingredients are almost entirely those of taste and smell, and are more or less characteristic of the different preparations.

The formaldehyd in the Formolid preparation in strength of 0.25 per cent. adds slightly to the antiseptic action of that preparation.

Camphor is more or less antiseptic and pungent, and promotes secretion. In strong solution it is slightly anesthetic.

Now the real question is: Do the foregoing multiple mixtures fill the requirements of the object aimed at therapeutically? As mouth-washes we wish at times antiseptic action, at other times cleansing action, at other times soothing and sedative action.

As antiseptic for the mouth and throat we cannot improve on the carefully localized applications of the tincture of iodin or of weaker solutions of iodin; when deemed advisable, of a strong solution of nitrate of silver carefully applied locally; or of local swabbing with strong hydrogen peroxid solution, or the more generalized washing or spraying with dilute solutions (provided that hydrogen peroxid is not applied to a deep ulcer or sinus where it can possibly cause disintegration of tissue). Strong preparations of glycerin and strong solutions of alcohol are other pleasant antiseptics, and the latter is decidedly astringent.

When a strong antiseptic is used, after it has acted for a few minutes, soothing washes or sprays should be used. Also it should be remembered that any simple cleansing wash (than which perhaps nothing is better than simple salt solution in so-called physiologic strength, 0.9 per cent., or ¼ teaspoonful of salt to about half a glass of warm water, to which may or may not be added another ¼ teaspoonful of sodium bicarbonate) is of value on an inflamed mucous membrane. After such cleansing of the membrane, the antiseptic may be directly applied, if such is indicated, or the cleansing and soothing gargle or mouth-wash just mentioned may be all that is needed. It is not the particular preparation that is used, or the particular ingredients in mouth-washes and gargles, but it is efficient washing and gargling that is of benefit.

The value of boric acid, not only in being mildly antiseptic, but also in promoting mucous secretion and therefore causing the easy removal of follicular exudates and membrane, should not be forgotten. Many times the insufflation of boric acid powder directly on the region involved is most efficient. At other times gargling of a solution in which boric acid is suspended is of value. While boric acid will dissolve in water only to about 4 per cent., a large surplus of boric acid should be left undissolved in the bottle. The bottle should be shaken, and the patient then gargles a boric acid solution which will deposit boric acid crystals on the throat, and will often be of as much value as though the powder were insufflated.

Perhaps the most pleasing pungent taste to the majority of patients is peppermint, and there is no reason for mixing this up with several other aromatics. If peppermint is disagreeable to a particular person, wintergreen may be substituted.

The following are formulas of a few simple solutions for mouth and throat washes:

		gm. or c.c.		
℞	Acidi borici	2		ʒ ss
	Potassii chloratis	5	or	ʒ i
	Aquae menthae piperitae .	200		fl℥ vi

M. Sig: Use as a gargle or mouth-wash, diluted or undiluted, as directed.

		gm. or c.c.		
℞	Sodii chloridi			
	Sodii boratis ....āā	2		ʒ ss
	Glycerini	50	or	fl℥ iss
	Aquae gaultheriae...q. s. ad	200		fl℥ vi

M. Sig.: Use as a gargle or mouth-wash, diluted or undiluted, as directed.

		gm. or c.c.		
℞	Acidi salicylici	2		gr. xxv
	Glycerini	25	or	flʒ v
	Aquae menthae piperitae, q. s. ad	200		fl℥ vi

M. Sig.: Use as a gargle or mouth-wash, diluted or undiluted, as directed.

The foregoing of course are only suggestions, and each physician should order the mouth-wash that he desires for his patient as carefully as he would write any other prescription. There is nothing wonderful or mysteriously curative in any of the formulas described, and simple home remedies will often be as effective as an expensive proprietary preparation, unless an antiseptic is required. Even simple starch water makes a very soothing gargle. The enormous literature offered by the Kolynos promoters is certainly not justifiable. No one would dispute that their preparations are more or less germicidal. On the other hand, it could be readily disputed that their combination was any more active than 25 per cent. alcohol in water or 25 per cent. glycerin in water, and a preparation of glycerin and alcohol with a mint taste may be ordered by any physician.

It is not our object to discuss the value of the various proprietary tooth-pastes. That the use of an antiseptic tooth-paste or an antiseptic mouth-wash, once or twice a day, will prevent acute infections that more or less enter through the nostrils must of course be denied. Strong antiseptic tooth-paste will not be tolerated by most gums, and it has been suggested above that one does not want the tooth-cleansing preparation too soapy, too irritant or too harsh.

If there is actual inflammation of the gums, medical or dental advice should be sought.

RECENT PROGRESS IN THE STUDY OF PNEUMONIA

It has been remarked before in these columns that the advent of a new and effective experimental method is almost invariably followed by achievements in the field of discovery. Accordingly, the possibility of producing a fatal lobar pneumonia with a relatively rapid course, by the Meltzer method of intratracheal insufflation of cultures of pneumococci, has already been the means of demonstrating some of the agencies which determine the severity of the symptoms and the nature of the outcome of a most dangerous disease. To-day it is the importance of the leukocyte in the resistance of animals to experimental pneumonia that has attracted our attention. Winternitz and his colleagues[1] at the Johns Hopkins Hospital have compared the influence of two related substances, one of which is powerfully leukotoxic, on the course of the disease. Benzene (benzol), one of the compounds selected, not only destroys the leukocytes in the circulating blood, but also affects the bone-marrow in particular, and other hemopoietic organs to a less extent. On the other hand toluene (toluol), which is methylbenzene, produces no demonstrable change in the number of leukocytes. Animals treated with the leukotoxic benzene rapidly succumb to an induced pneumonia, whereas those treated with toluene, a similar chemical compound causing no leukopenia, show no decreased resistance.

The rôle of the leukocyte in the resistance of animals to experimental pneumonia is further emphasized by the fact that animals which respond to a pneumococcus infection with a leukocytosis, which occurs after repeated injection of toluene, are more resistant to the disease. Moreover, hyperleukocytosis can be induced in other ways—by the repeated injection of protein substances, for instance—before the production of the pneumonia, likewise apparently increasing the resistance of the infected animals.

The further fact established by Kline and Winternitz, that the number of bacteria inoculated is one among the numerous factors determining the outcome of the disease, has made possible new studies in immunity. If a small number of organisms are injected, the animals usually recover. Repeated doses were therefore given. An active immunity was thereby developed and animals thus treated have been able to withstand repeated increasing doses of pneumococci intratracheally. The serum from animals actively immunized in this way may be used successfully to confer passive immunity against the homologous organism. This is a step in a hopeful direction.

Another recently studied feature of interest in connection with the symptomatology of pneumonia concerns the peculiar detrimental influence exerted by the microorganisms responsible for the disease on the capacity of the blood for combining with oxygen. Experiments *in vitro* have demonstrated that this is decreased when the pneumococcus is grown in blood and a comparable change is produced with even greater readiness in solutions of the respiratory pigment, hemoglobin. The lowering of the oxygen-combining power is apparently due to the formation of methemoglobin.[2] Analogous changes have now been demonstrated to take place in the animal body itself, when there is a severe pneumococcus bacteriemia.[3] The findings have even been extended to human cases.[4] In most patients with uncomplicated lobar pneumonia the decrease of respiratory surface is completely compensated for, and the oxygen content of the blood is within normal limits. In the terminal stage of the fatal cases of pneumonia in which death does not occur with great suddenness Peabody has found that there is often a progressive diminution in the oxygen content of the blood. Synchronous with this is a progressive decrease in the oxygen-combining capacity of the blood. These changes are usually seen in patients in whom an intense bacteriemia has developed, and are analogous to those found in the arterial blood of infected rabbits, and to those resulting from the growth of the pneumococcus in blood *in vitro* as mentioned above. It is logical therefore to explain all of these findings in the same way, namely, as probably the result of a change of oxyhemoglobin to methemoglobin, which no longer acts as a carrier of oxygen. It seems reasonable, further, to believe that in many cases of pneumonia this modification of the molecule of the blood pigment is an important factor in the immediate cause of death, for the terminal symptoms—toxemia, cardiac failure, polypnea, pulmonary edema and cyanosis—run parallel to the changes in the blood and may well be due in part to the deficient oxygenation dependent on them.

SENSITIZED VIRUS-VACCINE

Some years ago Besredka observed that if an otherwise lethal quantity of typhoid bacilli was mixed either with heated beef-serum or rabbit-serum and injected intraperitoneally into a guinea-pig, the animal would survive. The heated serum did not kill the bacilli and it was thought that the serum stimulated the leukocytes at the same time as it agglutinated the bacilli, and thus made them easier of attack by the phagocytes. He then soaked the bacilli in serum for a while, removed them by centrifugation and washed them in salt solution. In this case also the guinea-pigs survived the injection of what otherwise would have been a fatal dose. This experience led him to use specific antiserum for the treatment or sensitization of various germs before injection, thus eliminating everything in the serum except what would adhere to the bodies of the micro-organisms, namely, the specific antibodies. The injection of germs so treated produces a well-marked active immunity, and Besredka calls this kind of antigen or living vaccine "sensitized virus-vaccine."

---

[2] Butterfield, E. E., and Peabody, F. W.: Jour. Exper. Med., 1913, xvii, 578.

[3] Peabody, F. W.: The Oxygen Content of the Blood in Rabbits Infected with Pneumococcus, Jour. Exper. Med., 1913, xiv, 1.

[4] Peabody, F. W.: The Oxygen Content of the Blood in Lobar Pneumonia, Jour. Exper. Med., 1913, xiv, 7.

Vaccines of this nature have been prepared for a number of diseases, as typhoid fever, bubonic plague, cholera and dysentery. The antirabic vaccine used to prevent rabies at the Pasteur Institute in Paris is now a sensitized virus prepared by treating fixed virus with antirabic serum. Besredka asserts that the injection of sensitized living germs produces a more substantial immunity and a greater production of antibodies than the injection of germs killed by heat or in other ways. His chief support for this assertion is the results obtained in the immunization of apes against typhoid fever. In this case sensitized living typhoid bacilli gave absolute protection, causing no fever and no reaction, while killed bacilli failed to protect adequately. Apparently the method is harmless, at least so far as the typhoid virus-vaccine is concerned, as Besredka reports that about ten thousand persons, men, women and children, have been inoculated without a single mishap of any kind. Besides the possibility of acute infection, which seems to be extremely remote in view of these results, there is also the possibility that in some persons the injection of living bacilli might lead to the development of a carrier state, which would be very unfortunate indeed. It will require a great deal of experience before we can feel that we are justified in deciding one way or the other in regard to this possible danger of creating typhoid carriers.

Another important fact to be considered is that there is no evidence that in human beings sensitized living typhoid bacilli give any better protection than killed bacilli, which, as practical experience in the United States Army and elsewhere abundantly demonstrates, do protect against typhoid fever. Hence it will be necessary, before the general use as vaccine of sensitized living typhoid bacilli can be considered seriously, not only to overcome the fear of infection, of which there seems to be little or no risk, but also to demonstrate conclusively that there is no danger of making typhoid carriers and that the results produced are superior to those now obtained with dead bacilli. What is true of this virus-vaccine is of course true also of other similar vaccines, so that at present the obstacles to the use of such living germs for protective purposes would seem to be quite impassable.

THE PRINTING INDUSTRY AND SKIN DISEASE

During the past year or more an exceptionally large number of cases of disease of the skin presenting symptoms of pronounced similarity have occurred among the printers employed in certain newspaper establishments in Berlin. At the outset of the illness the patients exhibited in the skin about the hands and forearms—the only parts of the body ordinarily involved—a characteristic condition of inflammation. The skin was hyperemic and tense, unduly warm to the touch, and exhibited incipient blisters. Somewhat later in the progress of the cutaneous disturbance exfoliation and other signs of artificially produced eczemas put in an appearance, giving evidence of a localized disease of the skin such as is attributable to occupational conditions. The testimony of the workmen involved indicated that these peculiar pathologic skin manifestations had their beginnings with the introduction of trade substitutes for the oil of turpentine commonly employed in printing-offices to wash and clean the type that has been in use.

The newer products which have been employed to replace the oil of turpentine for removing the ink from printers' forms include benzin, lye, petroleum and certain kinds of pine oil. All of these are either of themselves obviously injurious to the skin, as is well known to be the case with strong lye, or they frequently contain irritating adulterants or impurities which are present owing to the imperfect rectification in the processes of manufacture. In one Berlin printing-office, in which nearly half of the workmen who had to deal with the type forms showed symptoms of skin disease, the diverse cleaning fluids used were in every case objectionable.[1] The oil of turpentine used was adulterated with impure benzene (benzol); the petroleum was poorly rectified. Both of these products, when pure in the best technical sense, are among the least objectionable of the cleansing reagents employed in this department of the printing industry. Skin disease has rarely been reported when they are adopted. To be safe for use in contact with the skin, petroleum should be free from acid and from certain complex organic impurities. Nearly all of the substitutes for oil of turpentine contain inferior benzin, which is decidedly toxic.[2] Benzin products are said to be finding their way into cheaper grades of paints and call for scrutiny from the point of view of danger to those who have to handle them. In the same Berlin printing-office a turpentine substitute used under the name of *Fütterin* was found to be a strongly alkaline, fields. Others are lying low, hoping that the storm will blow over and counting, doubtless, on the notoriously short memory of the public and the race-old tendency to be humbugged. The results of the *Tribune's* campaign are encouraging. The State Board of Health of Illinois will now feel that it has public opinion behind it in any action it may take toward revoking the licenses of the men who have sold their professional services to the scoundrels who own these advertising offices. The federal authorities which had had some of these individuals under investigation, previously, have brought matters to a head and have already secured the conviction and punishment of one quack. The Chicago *Tribune* has done one more public service and has increased the debt, already a large one, which the people owe it.

A DESERVED HONOR

The announcement of the call of Colonel Gorgas to South Africa to aid in determining the best method of handling epidemic disease among the workers in the mining district is a fitting recognition of the magnificent work which he has conducted in Panama. The contrast of the present sanitary conditions in the Canal Zone with those under French rule, under which every tie in the line of the Panama railway was said to represent a human life, is sufficient to account for the new honor which has come to Colonel Gorgas. In view of his previous record we have no doubt of further success in this new undertaking.

THE FORMATION OF CONJUGATED GLYCURONATES

The conjugation of sulphuric acid with substances of a toxic nature is one of the unique protective methods of the organism. Thus the phenol and cresols which are so commonly formed in intestinal decomposition are eliminated as salts of sulphuric acid; and a comparable reaction occurs in the chemical arrangement whereby the much-discussed indol is, after slight preliminary oxidation, converted into indican, the compound in the guise of which indol is excreted. A host of other aromatic substances, including those resembling phenol or which by oxidation are changed into phenols, such as thymol, anilin, naphthalin, pyrogallol and tannin, are similarly combined with sulphuric acid, with or without preliminary oxidation, and are accordingly converted into relatively harmless products readily soluble and rapidly eliminated. It is not so generally appreciated, though the fact has long been known and described, that the carbohydrate derivative glycuronic acid serves the same uses as sulphuric acid in being combined with aromatic compounds and to a certain extent thereby detoxicating them. This chemical means of defense against poisons is one apparently favored by the organism in the case of certain higher alcohols such as thymol, camphor derivatives, menthol, etc. Apparently the sulphuric and glycuronic acid conjugations supplement one another, the former serving most prominently as a general rule. Sulphuric acid is a final product of oxidative changes in the body and it is easy to understand how this can become available in these protective operations. It is an end-product ready for elimination. Glycuronic acid, on the other hand, is a readily oxidizable compound. Ordinarily it is not found in the blood or tissues. The question therefore arises as to how the conjugate glycuronates are formed in the organism. It appears from the recent studies of Hämäläinen[1] that the alcohols which have a tendency to enter into this protective reaction are first combined with glucose which is always readily available in the body. It is from such glucosid-like compounds that the glycuronates are subsequently derived. In evidence of this explanation Hämäläinen has succeeded in isolating the intermediate santenol glucosid when alpha-santenol (which normally leads to the formation of a corresponding glycuronate) was suitably introduced into the circulation. Accordingly the primary protective device in these cases seems to involve the cooperation of the simple sugar, glucose.

NOMENCLATURE

At its recent meeting[2] the American Roentgen Ray Society adopted an official nomenclature pertaining to roentgenology. The adoption of such a list to be used in medical literature is commendable. By a continued insistence on the use of words mutually agreed on, medical publications will aid in giving simplicity to a nomenclature already so complicated that understanding is difficult. These terms have been used by The Journal for some time and have been found satisfactory; uniformity makes more easy the indexing of papers and communications on any topic and avoids multiplicity of terms which complicate the editing of manuscripts and bewilder the reader.

THE MODE OF ACTION OF ATOPHAN—2-PHENYLQUINOLIN-4-CARBOXYLIC ACID

Trustworthy experimental evidence[3] leaves no doubt that two comparatively recent additions to the evergrowing list of synthetic drugs, namely, 2-phenylquinolin-4-carboxylic acid (atophan) and 6-methyl-2-phenylquinolin-4-carboxylic acid ethyl ester (novatophan), increase the elimination of uric acid in man. For the practical consequences of this effect as well as for purely theoretic reasons it becomes desirable to know precisely how the increase is brought about. It is conceivable, for example, that a greater production of uric acid is induced by the drugs—a result which would scarcely encourage their use in therapy; on the other hand, they may act by actually facilitating the elimination of preformed uric acid from the circulation. That the latter mechanism of action is the real effect of these drugs has been made more than likely by various observations and in particular the very recent American investigations of Folin and Lyman,[4] and Haskins.[5] The former investigators have shown the actual distinct lowering of the uric acid content of the blood after the use of 2-phenylquinolin-4-carboxylic acid in both normal and gouty subjects. Haskins noted the usual increase in the uric acid output attending the use of the drug; and inasmuch as this was followed up by an actual decrease of uric acid in the urinary content, these findings likewise favor the view that the drug merely stimulates the kidneys to abstract from the blood a greater quantity of the purin end-product than it normally would. The subsequent decrease follows as a compensatory consequence.

SNEEZEWEED

Throughout the United States there is found a well-known plant, *Helenium autumnale*, which is frequently grown for decorative purposes, owing to its large showy, yellow flowers that blossom in autumn. The popular names of this plant are numerous, ranging from the more familiar terms sneezeweed, autumn sneezewort, staggerweed—all expressive of a physiologic action—to the more descriptive designations of swamp sunflower, false sunflower, yellow star and ox-eye. The sternutative properties of the plant have long been recognized. Inhalation of the dust or powder of the dried plant or even chewing the leaves causes violent sneezing; and there is an account of an instance in which its use for interior floral decorative purposes was attended with a response of sneezing and weeping on the part of the persons present in the room. *Helenium autumnale* is known to have very marked poisonous effects on cattle, horses and mules, so that it is counted among the stock-poisoning plants of the West. Medicinally an interest in the species arises from the fact that it has been recommended as a therapeutic agent in the guise of a tonic, snuff, febrifuge and diaphoretic, as well as for "colds." A writer of a generation ago says of *Helenium*: "It is known and employed all over the country as a valuable errhine. The whole plant acts as such, but the flowers, especially the central florets, are the more powerful. It may be used in diseases of the head, deafness, amaurosis, headache, hemicrania and congestion of the head and jaws. The shocks of sneezing are often useful in these cases when other remedies hardly avail."[1] As a result of the investigations of Dr. P. D. Lamson[2] in Faust's pharmacologic institute at Würzburg it has now been shown that the pharmacologic behavior of a crystalline active principle, helenin, first isolated by Reeb,[3] corresponds with that of the entire plant. In view of the reputed medicinal uses of the latter, Lamson has considered the therapeutic possibilities of the newly discovered compound, the exact chemical structure of which still remains to be unraveled. Helenin cannot be classed as a protoplasmic poison and it has no noticeable action as an antipyretic. The preeminent property is that of a very active local irritant to mucous membranes in general. This explains the sneezing and lacrimation when the plant products come into contact with the mucous membranes of the nose and eye; the alimentary irritation attended with vomiting and diarrhea when the path of entry is the mouth, and the pain and edema following subcutaneous administration. In cases of lethal poisoning gastro-enteritis is the cause of death when the poison is given orally; after intravenous injection there is failure of the heart.

The difficulty in the absorption of helenin suggests a favorable property in its possible use as a vermifuge, provided an action on intestinal parasites could be demonstrated: but inasmuch as the intense local irritant action on the alimentary mucosa would exclude its use except in very dilute solution, a toxicity for parasites seems unlikely under this condition. As an errhine it is unquestionably active, and Lamson suggests that the plant itself may be a cause of fall hay-fever. Melted lard has been suggested as an antidote to *Helenium* intoxication in the case of cattle poisoned by the plant. In harmony with this it has been found that when oil is given by mouth the local irritant action of the isolated drug on the bowel is markedly alleviated. There is no suggestion of any interesting usefulness in the domain of therapeutic application as the result of the scientific investigation of helenin, but the toxicology of the plant is now made clear.

THE EFFECT OF FEEDING STARCH ON THE SUGAR CONTENT OF THE BLOOD

The question of the sugar content of the blood and its variation under the diverse conditions which arise in health and disease is a timely one. The studies of the past two or three years in this direction have been nothing short of helpful. They have contributed to the development of promising theories and therefore are likely to furnish something of value in the way of practice. For this reason we feel justified in recurring to the subject at frequent intervals.[1] It is tacitly assumed that in health the sugar content is a fairly fixed one so that it may be represented as a sort of physiologic constant. From recent observations in Minkowski's clinic[2] it appears that this is, strictly speaking, not a correct view. Starch is rarely charged with promoting a tendency to alimentary glycosuria, inasmuch as it is assumed to be digested with comparative slowness in contrast with the soluble sugars, and therefore to undergo absorption gradually, without overwhelming at any moment the organs that are entrusted with the storage and conservation of digested carbohydrates. Nevertheless Welz has found that even moderate amounts of starchy foods fed to individuals free from every manifestation of disturbed carbohydrate metabolism may bring about an undeniable and sometimes by no means inconsiderable increase in the sugar content of the blood—an amylogenous hyperglycemia. This is not sufficient to provoke glycosuria, and the figures obtained for the increment in ten normal subjects ranged from 0.04 to 0.08 per cent. of sugar. There are instances now recorded in which the content of blood-sugar was doubled by a meal of 200 gm. ($6\frac{2}{3}$ ounces) of bread together with 100 gm. ($3\frac{1}{3}$ ounces) of potatoes. It is not an incident of the meal *per se;*

[2] Welz, A.: Physiologische amylogene Hyperglykämie, Arch. f. exper. Path. u. Pharmakol., 1913, lxxiii, 159.

for after meat feeding no such "physiologic" hyperglycemia is noted. Evidently the niveau of the blood-sugar is far more responsive to dietary factors than has hitherto been believed. In other words, the physiologic adjustments of the body are singularly sensitive and delicate.

Medical News

COLORADO

Loses Bequest on Technicality.—Because of the ambiguity and vagueness of a paragraph in the will of R. L. Kaplan, millionaire philanthropist of Alabama, a bequest of $70,000 to the Jewish Hospital for Consumptives in Denver has been held null and void by the courts, because there are two Jewish institutions which maintain hospitals in Denver, and the terms of the will do not show clearly for which institution the bequest was intended.

Radium for Use of Physicians.—The first step in the plans of Alfred I. Dupont to use the output of the pitchblende mines for the use of the medical and scientific fraternity of the United States, was taken two weeks ago when he placed in the hands of Dr. Walter A. Jayne, Denver, a quantity of pitchblende ore with which to make experiments in the cure of disease. He also furnished Prof. L. F. Miller of the department of physics of the State School of Mines, Golden, some of the ore for scientific experimentation.

ILLINOIS

New Officers.—Wabash County Medical Association at Mount Carmel, October 29: president, Dr. John J. McIntosh, Allendale; secretary, Dr. John B. Maxwell, Mount Carmel.

Sanatorium for Rock Island.—Drs. Joseph De Silva, Bernard J. Lachner and Louis Ostrom, the commission in charge of the sanatorium project for Rock Island, have purchased for $5,000 a tract of land of nearly eight acres on which to establish a sanatorium. The commission has about $12,000 in hand at the present time. An administration building will first be erected, and other buildings as may be required.

Dental Examination Scandal.—As a result of charges made by a daily paper that a portion of the questions prepared for the examination to be held by the State Dental Board this week had been sold for $50 to a newspaper reporter, purporting to be a candidate for examination, new questions have been prepared and Dr. Peter T. Diamond, accused of having been a party to the sale of questions, has been temporarily removed from the Board of Dental Examiners.

Chicago

Personal.—Dr. Clarence H. Wall, police ambulance surgeon, who was operated on for hernia, October 21, is convalescent. ——Dr. Liston H. Montgomery has been appointed surgeon of the Eastern Division of the Chicago Great Western Railroad, to date from October 10.——Dr. Meyer Nuta has returned from Europe.

Safety Conference.—At a joint meeting of the Chicago Medical Society and the Public Safety Commission held November 5, the addresses made were on the lines of promoting unity between the physicians of the city, the public and the Safety Commission. Prof. Graham Taylor spoke on "The Public Burden of the Insecurity of Life;" Coroner Peter M. Hoffman, on "Safety First;" Dr. Frederick A. Jefferson, on "Suicide;" Dr. Daniel M. Eisendrath, on "Tetanus," and Dr. John D. Robertson, on "Hemorrhage, Concussion, Shock."

Special Gynecological Meeting.—At the special meeting of the Chicago Gynecological Society held in the Florentine Room of the Congress Hotel, November 15, at 8 p. m , papers were read by Dr. Lewis S. McMurtry, Louisville, on "The Foundation of Modern Gynecology and Abdominal Surgery;" by Prof. Dr. Kroenig, Freiburg, Germany, on "The Difference Between Former and Newer Treatments by X-Ray and Radium in Gynecological Diseases;" by Prof. Dr. Gauss, Freiburg, Germany, on "The Report of the Result of Radiotherapy in Gynecology;" by Dr. Thomas S. Cullen, Baltimore, on "The Umbilicus and Its Diseases," and by Dr. Robert L. Dickinson, Brooklyn, N. Y., on "Efficiency Engineering as Applied to Gynecological Surgery."

Exposure of Medical Quacks.—The Chicago *Tribune*, as the result of investigation of a group of firms and individuals operating in Chicago as medical specialists and preying on the ignorance of their patrons, suggests the advisability of further investigation by the police department. The investigation has been carried on for a considerable time with special reference to the advertising specialists who claim to cure "diseases of men." The firms and individuals thus far investigated are as follows:

"Professor Ehrlich," 303-304, 145 North Clark Street, said to be conducted by the Drs. Code.

Dr. Edward N. Flint, 322 South State Street.

Dr. Isaac Walter Hodgens, 35 South Dearborn Street.

Dr. Howe & Co., 120 North Dearborn Street, with Dr. Ward in charge.

Dr. Francis Leaverett Sweeny, 63 West Randolph Street.

Dr. Lewis E. Zins, 183 North Clark Street.

Dr. Bernard M. Ross, fifth floor Crilley Building.

Atomo-Radio Co., 48 West Randolph Street, Dr. Lawhon in charge.

At the City Council meeting October 28 an order was passed by unanimous vote calling on the corporation counsel's office to submit to the council at its next meeting a scheme whereby advertising medical swindlers can be driven from the city.——The State Board of Health has been asked by Gov. Dunne to present a statement concerning the legal status of these quacks.——At a meeting of the publishers of the Chicago Foreign Language Newspaper Publishers October 29, a resolution was adopted that the present campaign of the Chicago *Tribune* against the quack doctors who have been preying on the weak and unfortunate of the community so long a time unmolested, is entitled to the support and cooperation of all reputable journals.

IOWA

Hospital Opened.—The new miners' hospital, Albia, was formally opened October 27. Dr. T. Ernest Gutch, Albia, is in charge of the hospital, which is steam-heated and has accommodations for nine patients.

Public Health Education.—Drs. Mathew N. Voldeng, Cherokee, Henry Albert, state bacteriologist, Iowa City, Lenna L. Means, Des Moines, Jeannette Throckmorton, Chariton, and Paul E. Gardner, New Hampton, have been appointed members of the state societies' committee.

Sanatorium Notes.—The old Sac and Fox Indian School near Toledo is to be used as a tuberculosis sanatorium for Indian children.——The Associated Charities of Des Moines has decided to dispose of the Ridge Camp property. The tuberculosis hospital was discontinued in September.——The board of supervisors of Polk County has appropriated $5,000 for the erection at the County Farm of a hospital for the care of the tuberculous.

Physicians Win Suits.—In the case of Dr. Erasmus E. Birney, Nora Springs, charged with having performed a criminal operation resulting in the death of Miss Myrtle Irish, the jury sent in a unanimous verdict of acquittal.——In the suit of Dr. Soeren W. Staads, Sioux City, against Hollister Simmons, for $300 for an operation performed on Mrs Simmons, the defendant is said to have defaulted and judgment was given Dr. Staads for the amount claimed.

Personal.—Dr. Elijah M. Heflin, Calmar, is reported to be seriously ill at the home of his brother in Grand Island, Neb. ——Dr. Oliver J. Fay, Des Moines, has been appointed district surgeon for the Chicago and Northwestern System.——Dr. William R. Whiteis, Iowa City, has been appointed chief surgeon of the University Hospital, Iowa City, and also acting professor of surgery in the medical department, vice Dr. William Jepson, Sioux City, resigned.——Dr. Carroll C. Snead, Newton, is critically ill, the result of a cerebral hemorrhage. ——Dr. William D. Christy, Creston, is reported to be ill with cerebral hemorrhage.

New Officers.—Dallas-Guthrie County Medical Society at Panora, October 16: president, Dr. Samuel P. Free, Perry; secretary-treasurer, Dr. John V. Littig, Davenport (reelected). ——Council Bluffs Medical Society: president, Dr. William P. Hombach; secretary, Dr. John S. McAtee.——Southwestern Iowa Medical Society at Creston: president, Dr. B. L. Eiker, Leon; secretary-treasurer, Dr. Claire H. Mitchell, Weldon.——Bremer County Medical Association at Waverly: president: Dr. F. A. Osincup, Waverly; secretary, Dr. Ennis, Sumner.——Chickasaw County Medical Association in New Hampton, November 3: president, Dr. Alexander D. McKinley, Lawler; secretary-treasurer, Dr. Paul E. Gardner, New Hampton.——

Scott County Medical Society at Davenport, November 4: president. Dr. Peter A. Bendixen; secretary, Dr. John V. Littig, both of Davenport. The society adopted a resolution indorsing the Chicago *Tribune* for its fight on medical quacks.

MARYLAND

Work Begins on Hospital Annex.—Work was begun October 14 on a three-story annex to the Union Hospital, Elkton.

Die in Sanitarium Fire.—Two patients in the Edgemere Sanitarium, Govans, near Baltimore, were burned to death October 14, in a fire which practically destroyed the building. A nurse received serious burns while assisting patients to escape.

Personal.—Dr. P. Edward Stigers, Hancock, who has been ill with fever at the City Hospital, Martinsburg, is reported to be convalescent.——Dr. Oscar Fisher, Frostburg, was severely injured October 13 when his automobile overturned near Eckhart.——Dr. John E. Legge, Cumberland, has returned from abroad.

Baltimore

State Board Moves.—The State Board of Health, which has been located on East Franklin Street for several years, has moved to the Frank Brown Building on Saratoga Street. The board will occupy the second and third floors of the building.

Foreign Visitors.—Dr. Adolph Schmidt, professor of medicine in the University of Halle, Germany, had conferred on him the honorary degree of LL.D. by the University of Maryland, Virginia, November 11.——Dr. A. Loheenolt, Halle, Germany, is making a study of the hospitals of the city.

Personal.—Dr. Harry W. Plaggemeyer, who has taken charge of one of the departments of the Detroit General Hospital, was given a luncheon by fourteen Detroit physicians October 21.——Dr. Nathaniel Garland Keirle celebrated his 80th birthday anniversary October 10.——Dr. Adolph Meyer has returned from abroad.——Dr. Benjamin Swint has resigned as resident physician at St. Joseph's Hospital and has been succeeded by Dr. Edward F. Johnson.

MASSACHUSETTS

New Officers.—Holyoke Medical Association, October 7: president, Dr. John J. Carroll; secretary-treasurer, Dr. Fred H. Allen, both of Holyoke.

Addition to Hospital.—A building not to exceed $15,000 is to be erected by the City of Boston and then cared for by the trustees of the Newton Hospital. The building will be a part of the present hospital group.

Personal.—Dr. David Fisher, Atwater, said to be the oldest alumnus of Yale, celebrated his 96th birthday anniversary at Springfield, recently.——Dr. John R. Slattery, South Boston, has been honored by the pope by being made a Knight of the Holy Sepulchre.

Academy Opens Clubhouse.—Nearly 500 physicians and their families of Western Massachusetts were present at the opening of the new home of the Springfield Academy of Medicine on State Street. A mansion, which was purchased several years ago, has been transformed into a clubhouse. The first formal meeting of the society in its new home was held October 14.

Fitz Memorial Meeting.—In the medical school buildings of Harvard University, Boston, there will be held on November 17 at 8:15 o'clock, a memorial meeting to the late Reginald Heber Fitz, professor emeritus of the theory and practice of physic. Addresses will be made on that occasion by Prof. W. W. Keen, Philadelphia; Charles W. Eliot, president emeritus of Harvard University; Dr. Henry P. Walcott, chairman of the State Board of Health; Dr. William Sydney Thayer, Baltimore, and Dr. William T. Councilman of Harvard University. The general medical public is invited.

Changes in Medical Corps.—The following changes of assignments of officers of the medical corps, M. V. M., are announced: Major John D. R. Woodworth is relieved from command of the Hospital Corps, but will be in command of Field Hospital, No. 1, until otherwise ordered; Capt. George F. Keenan is assigned to command Ambulance Company No. 1; Lieuts. Oscar Dudley and Leonard W. Hassett are relieved from duty with Field Hospital No. 1 and assigned to duty with Ambulance Company No. 1, and Lieuts. George L. Howland and Charles R. Morgan are relieved from duty with Ambulance Company No. 1 and assigned to duty with Field Hospital No. 1.

MINNESOTA

New Officers.—Blue Earth Valley Medical Society, in Blue Earth, October 23: President, Dr. Peter F. Holm, Wells; secretary, Dr. John A. Broberg, Blue Earth (reelected).

Placarding for Tuberculosis.—The State Board of Health has passed a rule authorizing and directing local health officers to placard premises where tuberculosis exists if proper precautions are not being taken by the patient or those in charge of the patient to prevent contagion.

Personal.—Dr. Carl J. Holman, Mankato, is under treatment at the Emmanuel Hospital for fractured ribs and an injury to the leg sustained in a fall at Valley Grove, recently.——Dr. Henry E. Michelson of the staff of the McIntyre Hospital, Virginia, has been appointed assistant health officer of Virginia.——Dr. Joseph Nicholson, Brainerd, has been elected chief surgeon of the Minnesota Central Railway Company.——Dr. O. A. Oredson, Duluth, has sailed for Europe.

Sanatorium Notes.—Renville and Watonwan counties have appropriated $5,000 and $6,000, respectively, for the construction and maintenance of county tuberculosis sanatoriums.——Otter Tail County Tuberculosis Sanatorium at Otter Tail Lake was formally opened October 30. The institution is admirably arranged and equipped and has accommodation for thirty-seven patients. Fourteen applications for admission have thus far been received.——Lincoln, Murray and Lyon counties have agreed to erect a central sanatorium.——Goodhue County has appropriated $15,000 to be used in the erection and equipment of a tuberculosis sanatorium. To this will be added a similar amount given by the state.

MISSOURI

Personal.—Dr. E. W. Caveness has resigned as superintendent of the Kansas City Municipal Farm, but will continue as physician of the institution.——Dr. William P. Simpson, Chilicothe, was seriously injured by a fall October 23.——Dr. John W. Dean, for forty-five years a practitioner of Maryville, has retired from practice.——Drs. Woodson Moss, James Gordon, Joseph E. Thornton and David H. Dolley have resigned as members of the Board of Health of Columbia.

St. Louis

New Officers.—St. Louis Pediatric Society: president, Dr. Jules M. Brady; secretary-treasurer, Dr. T. C. Hemplemann.

Building Presented to Hospital.—The Barnard Free Skin and Cancer Hospital has been presented by Mrs. Barnard with the building immediately east of the hospital building, to be used as a home for nurses. The house will be known as the Mrs. George D. Barnard Home for Nurses.

Personal.—Dr. Frederick A. Baldwin has been appointed chief of the state department of bacteriology, vice Dr. Downey L. Harris, resigned to accept the position of professor of hygiene and preventive medicine in the St. Louis University Medical School.——Dr. C. W. Scharff has been appointed resident physician at the City Hospital.——Dr. Daniel C. Goodman was injured in an automobile accident in New York City, October 12.——Dr. Frank Wild suffered a fracture of the right shoulder October 9, when the tongue of a wagon was driven through the window of a street-car in which he was sitting.——Dr. R. Lilburne Byrd is under treatment in the Mullanphy Hospital on account of an infection of the jaw and neck.

NEW YORK

Pediatric Club Formed.—Physicians of Syracuse, Utica and Oswego have formed a pediatric club with membership limited to fifteen.

New Officers.—Suffolk County Medical Society at Riverhead October 30: president, Dr. Silas K. Corwith, Bridgehampton; secretary-treasurer, Dr. Frank Overton, Patchogue.

Honors Dr. Archambault.—The Medical Society of the County of Albany at its meeting in Cohoes, October 22 adopted resolutions eulogizing the life and medical work of the late Dr. Joseph L. Archambault.

New York City

Personal.—Dr. H. Sheridan Baketel, Manhattan, and Dr. Philip M. Schaffner and Robert I. Bull, Brooklyn, have been appointed instructors in genito-urinary diseases in Long Island College Hospital, Brooklyn.

NORTH CAROLINA

Prescriptions of Alcohol.—The report of the Asheville police inspection of physicians' prescriptions for alcoholic intoxiin numbers it stands at the head of all medical organizations of the world; moreover, that the papers and proceedings of the Association are disseminated all through the profession through the avenue of The Journal.

The presidential address by Dr. George Emerson Brewer, New York City, concerned "A Preliminary Report on a Simple and Rapid Method of Pyloric Closure in Gastro-Enterostomy."

Dr. Harvey Cushing, of Boston, reported 156 cases of operations on the gasserian ganglion with two fatalities, which occurred in the earlier cases.

The paper was discussed by Dr. John B. Murphy, Chicago.

FOREIGN

Death of Klebs.—Edwin Klebs, the veteran pathologist and bacteriologist, died at his home in Dortmund on October 21. The passing of this eminent man, once a professor of pathology in the Rush Medical College, removes one of the last of the original champions of the bacterial theory of infection. A native of Königsberg and a cousin of Leyden, Klebs had followed Virchow's lectures at Würzburg and became his assistant at Berlin in 1861. After attaining his professorship at Bern in 1866, his scientific career was that of a péripatetic. He held in succession the chairs of pathology at Würzburg (1872), Prague (1873), Zurich (1882), Chicago (1896), and during his period of retirement resided variously at Carlsruhe, Hannover, Berlin, Lausanne and Dortmund. His treatises on pathology (1869-76), in particular the larger *Allgemeine Pathologie* (1887-89), are highly esteemed by the masters of this science as solid thorough-going works of enduring value. But he will be best remembered in the future as the pathbreaker and the precursor. His name is permanently associated with the discovery of the diphtheria (Klebs-Loeffler) bacillus, which he was the first to see and to recognize as the cause of the disease (1883), while Loeffler tried the organism out by Koch's postulates and dissociated it from the bovine and avian varieties (1884). Not only did Klebs see the typhoid bacillus before Eberth (1881), but he antedated Koch by seven years in the bacteriologic investigation of the traumatic infections (1871) and also made solid cultures before him. Klebs was the first to investigate the bacteriology of gunshot wounds (Franco-Prussian war, 1871-72), was on the threshold of the theory of filterable viruses in his studies of anthrax (1871), made some of the initial studies on mycotic and experimental endocarditis (1875), first produced bovine infection of perlsucht by feeding with milk (with Gerlach, 1873), and, in 1900, he first attempted to treat tuberculosis with the bacilli of cold-blooded animals, the species selected being the sloe-worm bacillus *(Blindschleichenwurmbacillus)*. Indeed, Klebs will always be recognized in medical history as having done most to get the pathologists away from the solidist views of Virchow by emphasizing the fact that postmortem findings are, after all, only end results and that true causation of infectious diseases is to be sought in parasitic agents coming from the outside world. A broad-browed, broad-minded savant of the Prussian type, it was his temperamental peculiarity to fling himself into the "imminent deadly breach" and break many a pathway, leaving it to others to follow up and complete his work.

CANADA

Personal.—Dr. Joseph N. Roy, Montreal, has gone on a pleasure trip to Argentine, Peru and Chili.——Dr. J. Y. Ferguson, Renfrew, Ontario, who has been in Japan for several years as a medical missionary, is home on furlough.——Dr. F. F. Carr Harris, Toronto, has entered the missionary service at Honan, China.

Hospital News.—Montreal has just started erecting a new Foundling and Baby Hospital. Up to May 1 last the citizens contributed $42,000 for the purposes of such hospital, and as Colonel Burland and his sisters had agreed to duplicate any amount raised from the citizens, the total collection amounted to $85,000, sufficient to warrant the hospital authorities in commencing building operations. The new institution will provide for several times the accommodation of the old one, which was forty-two patients. A milk station will be run in connection with the hospital and a special and prominent feature will be a school of instruction in the caring of babies. The foundling hospital was started twenty-two years ago, and the death rate during the first year was 80 per cent. Last year the death rate was 13½ per cent. During the six months just past but one baby died out of fifty, while 400 were refused admission owing to lack of room. The hospital has demonstrated that much good work can be accomplished along this line in preventing infant mortality in Montreal.

PARIS LETTER

(*From Our Regular Correspondent*)

Paris, Oct. 31, 1913.

Lucas-Championnière and Prehistoric Trephining

Dr. Lucas-Championnière, whose death I mentioned in my previous letter and who was the author of important works on trephining guided by cerebral localizations, was interested in the study of prehistoric trephining. This was the subject of the lecture which he was to have given October 25, as a delegate of the Académie des Sciences, at the annual public session of the five academies. In this, after reviewing more or less fantastic hypotheses of the reason for this practice, he adopted a much more simple and plausible interpretation. Among all primitive peoples fractures of the skull are frequent. When splinters of the bone are driven into the head, men are often led to pick out these splinters for the sake of curing the terrible pain of intracranial pressure. Gradually, having very crude ideas of the relation of cause and effect and no ideas of anatomy, primitive man is led to open the skull of other subjects who have similar pains. Centuries confirm his practice of intervention. Exact and repeated observations lead him to fix on the technic of opening the skull for those pains which characterize intracerebral tension in the course of various diseases. This fact is the less surprising because savage or barbarous peoples have not the same aversion to surgical operation as civilized persons. Pronounced insensibility, habituation to traumatism, the resignation of the patient overcome with pain, and even curiosity, contribute to make savages accept an operation with less fear than civilized persons. Such distrust as they may have felt probably disappeared the more easily, because, whatever may be thought of it by surgeons who lose their patients by purulent infection, the mortality was very low. Recovery and relief from pain was the rule. It is still so among the Kabyles. During the visit of Lucas-Championnière to Biskra thirty years ago, a man showed him four perforations in his own head, and gave him exact details of the operation, in which he had great confidence, for, as he said, his brothers and himself had been trephined twelve times by their own father. These operations are performed especially for terrible pains of the head. This man said to Lucas-Championnière that if the latter would stay three days longer, he would certainly be able to find some one to perform a trephining operation before him.

The Disadvantages of White Flour

At one of the last sessions of the Société de thérapeutique, Dr. Monteuuis read a paper showing the superiority of old-fashioned flour over patent process flour. The first is merely wheat ground fine, in which 20 per cent. of the envelopes are removed in the form of coarse bran. This is the flour which makes natural bread, farm bread, old-fashioned bread. In "patent" flour there is removed from the wheat not only the coarse bran but the fine bran and the germ. The first layer of the wheat berry, the richest in all points of view, is entirely removed and used for feeding cattle. The second layer is partially removed and used for brown bread. Fine white bread contains only the inner portion; that is to say, about one-half the grain is sacrificed, and this waste costs France 400,000,000 francs ($80,000,000) a year. From the point of nutrition, the old-fashioned flour is not only superior but it is better digested and is the mineralized food par excellence.

The Twenty-Sixth Annual Meeting of French Surgeons

This meeting was held in Paris, October 6 to 11, under the presidency of Dr. E. Kirmisson, professor of clinical surgery of the diseases of children in the Faculté de mèdecine de Paris. His opening address was on the subject of orthopedic surgery.

TREATMENT OF HEAD WOUNDS MADE BY SMALL PROJECTILES

Two papers were devoted to it, one by Dr. H. Billet, military physician, on wounds made by war projectiles, the other by Dr. A. Demoulin, surgeon of the hospitals of Paris, who considered only the wounds of civil life.

In war the indication for operation is hemorrhage, or signs of cortical irritation. In uncomplicated perforation in which the projectile lodges in the head, the general rule is to refrain from operation, but it is necessary to watch over the patient carefully, for often an operation is warranted later. Tangential wounds, on the other hand, imperatively demand active and early operation, even in the frequent cases in which the symptoms are not alarming, for secondary infection here is the rule. In fact, statistics prove that the mortality is 20 per cent. if operation is not performed. Operation ought to be performed only when facilities for operation with perfect asepsis are obtainable. Secondary operation is necessary under three circumstances: (1) to ward off infection (the ordinary case); (2) to extract a projectile or foreign body; (3) to treat one of the late complications which darken the prognosis.

In civil life the usual wounds are those of automatic revolver bullets. If the patient has just been wounded, the wound should not be explored, and the region of the wound should merely be disinfected with tincture of iodin and dressed aseptically. When conditions permit of aseptic surgery, preventive trephining should at once be performed, the lesions should be followed step by step, the focus cleansed, splinters of bone removed, and the bullet extracted; but one should not exceed the limits of the wounded nervous zone. When, after preventive trephining, lumbar puncture shows infection of the cerebrospinal fluid, the fluid should be evacuated daily, and if the symptoms do not tend to disappear, the skull should be opened in order to drain the subarachnoid space. When the bullet has not been removed and becomes troublesome, operation is expressly indicated; but if the projectile is broken into a number of fragments which apparently cannot be removed by a single orifice, trephining operation is contra-indicated in spite of the seriousness of the symptoms.

Professor Lejars of Paris agreed with Dr. Demoulin in thinking that in non-military wounds of the head caused by small projectiles, even though they appear to be benign, it is always necessary to operate. Professors J. Vanverts and Auvray, *agrégés* at Lille and at Paris, respectively, also agreed; but the latter believed that the operation ought to be as simple as possible, and the brain not compressed by a tampon under the pretext of drainage. One drain is enough. Dr. Oser of Vienna, on the other hand, did not believe that it was necessary to operate in all cases, but only if clinical symptoms were present. Dr. Peugniez of Amiens remarked that care should be taken not to disturb the skull after roentgenoscopy, for the projectile may become displaced in the course of operation.

Dr. Willems of Ghent, who was on the ambulance staff in Servia, said that the Balkan War had demonstrated the value of the evacuation of the wounded all the more in that country where there were no means of rapid communication, and the distance of the battle-fields was great. Most of the wounded who were thus removed were benefited. Professor Delorme, medical inspector general of the service of military hygiene, however, did not agree, at least so far as head wounds were concerned. He thought it better to operate in the ambulance or near the battlefield. This also was the opinion of Dr. LeFort, professor *agrégé* at the Faculté de médecine de Lille, who observed that in the Balkans soldiers wounded in the head and sent to the rear without operation arrived there too late to be operated on.

An Atoxic Antigonococcic Vaccine

At a recent session of the Académie des Sciences, Dr. Charles Nicolle, director of the Pasteur Institute of Tunis, and Dr. L. Blaizot presented an interesting paper on an atoxic antigonococcic vaccine which they had prepared. During the seven years that vaccine treatment of gonorrhea and its complications has been attempted, this method has not yet won the favor of the medical profession. Experimenters up to the present have been unable to surmount the difficulty presented by the toxicity of vaccine. Nicolle and Blaizot have succeeded in completely suppressing the toxicity of antigonococcic vaccines while obtaining a stable product which preserves its therapeutic properties indefinitely just as serum does. Their method is applicable to other microbes. They are reserving the publication of the method until their experiments shall have been finished. The curative power of the atoxic vaccine is considerably increased. When inoculated in small doses, like other vaccines, it produces a much more rapid cure. In larger doses it shows a greater efficacy without causing the least local or general reaction. Its efficacy is shown by the following statistics: Twenty-four cases of gonorrheal ophthalmia have all resulted in cures in from three to ten days, the inoculations being repeated every day or every other day; 20 patients with gonorrheal orchitis were cured by from four to six inoculations repeated every other day; 3 patients with gonorrheal rheumatism were cured after from two to eight inoculations repeated every two or three days; 127 patients with acute or chronic urethritis were cured rapidly after seven or eight inoculations.

BERLIN LETTER

(*From Our Regular Correspondent*)

Berlin, Oct. 24, 1913.

Personal

Professor Steyrer of Greifswald has been called as director of the medical clinic in Innsbruck as successor of Professor Schmidt, who has been called to Prague.

Professor Michaud of Kiel has been appointed in place of the deceased Bourget, as professor and director of the medical clinic in Lausanne.

Annual Meeting of German Neurologists

At the annual session of the Society of German Neurologists, held under the presidency of Professor Oppenheim of Berlin early in October, Professor Lewandowsky of Berlin made a report on a collective investigation regarding the position of neurologists in the universities, hospitals, etc., and called attention to the small number of professorships for this specialty and of clinics available for neurologists, and noted the fact that in this respect Germany is excelled by Russia and other countries.

Ehrlich, v. Wassermann and the Vienna pharmacologist, Hans Horst Meyer, were elected honorary members of the association.

The Erb medal, which is awarded every three years for merit in the field of nerve therapy, was received this year by the neurologist, Docent Dr. Barany of Vienna.

DEGENERATIVE PROCESSES IN THE NERVOUS SYSTEM

This was the first subject on the program and it was presented by Professor Alzheimer of Breslau. Elements of the central nervous system which have degenerated, are converted into simpler chemical products by the help of the cells of the connective tissue, and are removed from the nervous tissue. This decomposition (*Abbau*) is accomplished in various ways according to the form of the injury and the extent of the nervous tissue injured. Four forms of decomposition processes can now be distinguished: (1) the mesodermal form of decomposition, which is produced by the cells of the connective tissue, in case a circumscribed part of the nerve tissue together with connective tissue is destroyed (wound, hemorrhage, etc.); (2) the ectodermal form of decomposition by elements of the glia, either (*a*) by the glial granular cells in case of the destruction of the medullary sheath without injury to the neuroglia (secondary degeneration, disease of the tracts in the cord, etc.), or (*b*) by the action of ameboid glia cells, especially in severe infections and intoxications, or (*c*) by the glia cells present without the new formation of special kinds. In addition to these, there are other forms of decomposition which have not yet been fully explained. The study of the decomposition processes with the new methods introduced by Alzheimer into the histopathology of the nervous system, have very markedly increased the possibility of recognition of the anatomic bases for mental and nervous diseases; it permits the recognition of the destruction of separate nervous elements, even in cases in which with the older methods lesions could not be demonstrated. The recognition of the connection between various striking histologic features as stages of the same pathologic process, and estimation of the age of pathologic lesions are also made possible by the application of the newer methods.

AMAUROTIC IDIOCY OF LATE INFANCY WITH CEREBELLAR SYMPTOMS

Professor Bielschowsky of Berlin discussed this form of family amaurotic idiocy of which hitherto not much has been known. It assumes a peculiar position because in the clinical picture and in the pathologic findings the indications of hereditary cerebellar ataxia are pronounced in addition to the typical pathologic signs of amaurotic idiocy.

SYPHILIS IN CONNECTION WITH TABES AND PARALYSIS

According to Professor Erb of Heidelberg, metasyphilis is to be regarded, in view of recent investigations, as a genuine syphilitic disease, although of a peculiar character. One of the chief problems consists in the investigation of the biology of the *Spirochaeta pallida* (different races, the changes which the same undergo in repeated passage, by antigens, special predisposition of the host, etc.). The occurrence of nervous syphilis can, with little doubt, be referred to the neurotropic peculiarities of certain races of spirochetes. With reference to the pathogenesis of gliovascular and purely degenerative changes there are still differences of opinion. For the former, a direct action of the spirochetes is probable.

STUDY OF PAIN, ESPECIALLY AMONG THE NEUROTIC

Oppenheim of Berlin called attention to the fact that in diseases of the glands of internal secretion, such as exophthalmic goiter, for instance, pain may precede the other symptoms for years. This can probably be referred to a diminished or increased secretion of some gland or glands, or to the production of chemically irritating materials (hormones). The same explanation may apply also to the algias (painful conditions) of the menopause, of paralysis agitans and many acroparesthesias.

The pains in hysteria and neurasthenia have various origins. There are psychic forms (psychalgias) both ideogenous, as, for instance, the fear of cancer, as well as emotional; generally these two factors are united. More frequent than the pure psychalgias are forms of pain which have a physical basis (local irritations, fatigue, traction on muscles, gastro-intestinal disturbances, gout, diabetes, etc.); but the hyperesthesia, focusing of the attention, persuasion and increased introspection of the morbidly nervous transform their slight temporary pains into permanent painful affections. An essential rôle is played in these cases also by the vasomotor diathesis with its tendency to cramps of the vessels, and further the inherited transmission of pains in the direct or transferred form.

Von Frankl-Hochwart of Vienna called attention to the fact that pains of psychic origin do not recur in dreams as is the case when they proceed from an organic basis. Dubois of Bern stated that he has been able sometimes to relieve and cure pain by his method of explanation and persuasion, even in cases of pain apparently permanently rooted for fifteen years, which had defied all other methods. On the other hand, Trömner insisted that there is much of suggestion in the action of Dubois' method, which the latter energetically denied. The convincing of the person, persuading him to see the matter in its proper light, are the effectual elements, and the personality cooperates with it. With suggestion, as Dubois emphasized, it is necessary to instill into the patient opposing ideas. Oppenheim, in conclusion, insisted that the method of Dubois of simple explanation and instruction is not sufficient in many cases of neurosis.

MENINGITIS WITH APPARENTLY NORMAL CEREBROSPINAL FLUID

In the febrile diseases of children, Professor Förster of Breslau has frequently observed a severe clinical picture of meningitis without change in the lumbar-puncture findings. After the disappearance of the meningitic symptoms there remained a cerebellar disturbance of the gait which also after weeks and months completely disappeared. The cases were in tuberculous children.

EXOPHTHALMIC GOITER IN MEN

Mendel and Tobias of Berlin discussed Basedow's disease in men. Men are less frequently affected with this disease than women (in the proportion of 1:6), and in general at a later age. The thyroid may be little, if any enlarged, but the sexual functions, in contrast with women, are rather diminished; early arteriosclerosis frequently occurs as a complication and pronounced psychoses are more common in men. Internal therapy is, as a rule, sufficient.

SERODIAGNOSIS IN NEUROLOGY

Golla of Breslau gave the results of Abderhalden's serodiagnosis in brain and spinal-cord diseases. The serum from fifty-eight persons with organic brain or spinal-cord disease was investigated. In a number of these, the process showed a fermentative destruction of the nerve tissues. This condition was almost constant in paralysis, in which, in contrast to other organic processes, other organs also were digested.

Alcohol and Responsibility in the Academic Course

The faculty of the University of Bonn have posted the following notice on the blackboard: "Among the cases of discipline coming before us for decision, we again and again have the experience that the students present the excuse that they were drunk or so drunk that they did not know what they were doing. Some recent instances of this impel us to give notice that we are not accustomed to give any weight to this form of defense in general, and do not recognize drunkenness as a ground of extenuation. The students of the university fortified by a long course of training in character, must be expected to have reached such a degree of self-control and strength of will that they do not lose control of their sense, and of their actions by excessive use of alcohol. If the student acts contrary to this duty, he must bear the consequences."

Marriages

Charles S. Ryttenburg, M.D., Port Chester, N. Y., to Miss Anita Lazaron of Mount Auburn, Cincinnati, October 27.

William Johnson Bass, M.D., Paducah, Ky., to Miss Charlotte Cecelia Dean of Henderson, Ky., October 22.

John George Mueller, M.D., to Miss Margaret Corridan, both of Iowa City, at Des Moines, Ia., October 27.

Augustine Charles Luhr, M.D., St. Marys, Pa., to Miss Mary Gertrude Wall of Pittsburgh, October 15.

Charles Pulford Forward, M.D., Dubuque, Ia., to Miss Myrtle Anne Gilstrap of St. Louis, June 29.

Arthur Preston Flowers, M.D., to Miss Margaret Louisa Ashford, both of Atlanta, Ga., November 8.

Robert Turner, M.D., Paris, France, to Miss Marjorie Pope of Brookline, Mass., in Paris, October 23.

Marie Kirby Hopkins, M.D., Gloversville, N. Y., and Walter Humphrey, in Castile, N. Y., October 20.

Adolph E. DeTuncq, M.D., Scandinavia, Wis., to Miss Marvel Drewry of Milwaukee, September 20.

Samuel Caldwell Benedict, M.D., Athens, Ga., to Mrs. Kate Taylor of Macon, Ga., October 23.

George William Prichard, M.D., Omaha, to Miss Ina Fogelstrom of Wahoo, Neb., October 29.

Charles William Pace, M.D., to Miss Effie Coppage, both of Hot Springs, Ark., October 12.

William Henry Tippie, M.D., to Mrs. Anna R. Ullery, both of Terre Haute, October 25.

Henry Stine Weigle, M.D., Harrisburg, Pa., to Miss Esther Noble of Muncy, Pa., October 25.

Robinson Bosworth, M.D., St. Paul, Minn., to Miss Russell Sprake of Chicago, November 3.

John Robins Blair, M.D., to Miss Ethel May Smith, both of Richmond, Va., October 22.

John Guirley Missildine, M.D., to Miss Sara Taft, both of Parsons, Kan., October 15.

Archibald B. Elkin, M.D., to Miss Amelia Sturgeon, both of Atlanta, Ga., October 21.

John H. McCool, M.D., to Miss Katharine Blackwell, both of Indianapolis, October 15.

Charles M. George, M.D., to Miss Mary E. Yorks, both of Detroit, Mich., October 28.

Deaths

Charles McBurney, M.D.—Four weeks ago The Journal chronicled the death of Dr. Reginald Heber Fitz, who called attention to the pathology of appendicitis and thus opened the way to a clearer understanding of the disease and the possibility of its cure by surgical means. To-day we note the death of Dr. Charles McBurney, whose operative work in appendicitis brought him into great prominence during his years of active work, and whose recognition of a point of localized tenderness in appendicitis has made McBurney's point known the world over.

Charles McBurney was born in Roxbury, Mass., Feb. 17, 1845, the son of Charles and Rosine Horton McBurney. He received his academic training in Harvard, from which he received the degree of A. B. in 1866, and that of A. M. in 1869. His medical course was taken at the College of Physicians and Surgeons, Columbia University, New York City, from which he was graduated in 1870. His teaching work commenced in his alma mater in 1872 as assistant to and demonstrator of anatomy from 1872 to 1889. During a portion of this period from 1878 to 1882, he was lecturer on anatomy of the nerves and surgery. In 1889 he was made professor of surgery; three years later professor of clinical surgery, and in 1907 he became emeritus professor of surgery.

During his forty years of practice in New York City he was a member of the visiting or consulting staff of many hospitals. He was a Fellow of the American Medical Association, an honorary Fellow of the Royal College of Surgeons, Edinburgh, a member of the New York Academy of Medicine, the Surgical Society of Paris, the Roman Medical Society, the Medical and Surgical Society of Constantinople, and many other learned bodies. His first contribution to the medical literature of appendicitis appeared in 1889 when he published an essay on "Experience With Operative Interference in Cases of Disease of the Vermiform Appendix."

For several years Dr. McBurney had been retired from practice and resided in Stockbridge, Mass. From his home in this place he was summoned to Buffalo in 1901 as a consultant when President McKinley was shot.

He died suddenly from heart disease at the home of his sister in Brookline, Mass., November 7, aged 68.

In addition to his work in appendicitis which brought to American surgery recognition from the entire world, Dr. McBurney was a pioneer in aseptic technic.

Jesse S. Myer, M.D. Marion-Sims College of Medicine, St. Louis, 1896; a Fellow of the American Medical Association; lecturer on physiology and clinical chemistry and microscopy in St. Louis University from 1898 to 1902; assistant instructor and lecturer on clinical chemistry and microscopy from 1901 to 1912 and associate in medicine thereafter; visiting physician to the St. Louis City Hospital; associate physician to the Jewish Hospital and physician to out-patients in Washington University Hospital; author of a biography of Dr. William Beaumont; died at his home in St. Louis, October 29, from leukemia, aged 40.

Charles Buckner Hardin, M. D. Kansas City (Mo.) Medical College, 1881; Bellevue Hospital Medical College, 1883; a Fellow of the American Medical Association; formerly president of the Jackson County Medical Society and the Kansas City Academy of Medicine; for several years professor of hygiene and state medicine in the Medico-Chirurgical College of Kansas City; died at his home August 31, aged 56.

Samuel Hughes Chute, M.D. Medical College of Ohio, Cincinnati, 1851; since 1857 a resident of St. Anthony and Minneapolis, Minn.; supervisor of the poor and city treasurer of St. Anthony; a member of the city council of Minneapolis for several terms, and a member and president of the board of education; died in St. Mary's Hill Sanitarium, Milwaukee, October 12, aged 83.

Oscar Chrysler, M.D. Detroit College of Medicine, 1892; a Fellow of the American Medical Association; assistant surgeon at the National Soldiers' Home near Milwaukee, Wis., until 1902, and since that time chief surgeon of the institution; was killed in an explosion that wrecked the sterilizing apparatus in the basement of the hospital, October 29, aged 48.

Isaac N. Snively, M.D. Jefferson Medical College, 1863; formerly a member of the American Medical Association; a member of the Medical Society of the State of Pennsylvania, and the Western Maryland Railroad Surgeons' Association; local surgeon of the road at Waynesboro, Pa.; died at his home October 31, from cerebral hemorrhage, aged 74.

Henry Archer Mettauer, M.D. Randolph-Macon College, Prince Edward Court House, Va., 1849; a pioneer practitioner of Macon, Ga., where he had practiced for more than sixty years; one of the old Southern school of gentlemen; a family doctor, universally beloved; died at his old home in Farmsville, Va., October 22, aged 87.

James Thomas Harris, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1877; a member of the Medical Society of the State of California; at one time coroner and physician of Santa Clara County, and for several years city physician of San Jose; died at his home October 31, from cerebral hemorrhage, aged 75.

Hugh Logan, M.D. Washington University, St. Louis, 1872; a Fellow of the American Medical Association, and a pioneer physician of Eastern Oregon; local surgeon for the Oregon-Washington Railway and Navigation Company at The Dalles for several years; died at his home, October 27, from pneumonia, aged 63.

Edith Earle Eayre Keisker, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1908; a medical inspector of public schools of Philadelphia who was making a study of scarlet fever in the municipal hospital, contracted the disease, and died in that institution, October 24, aged 35.

Stewart L. Henry, M.D. Tulane University, New Orleans, 1866; for forty years a practitioner of Orleans Parish, and for several terms a member of the state legislature; a surgeon of U. S. Volunteers during the Civil War; died at his home in Carrollton, New Orleans, October 11, aged 79.

Samuel Senseny Huber, M.D. Jefferson Medical College, 1865; for many years a practitioner of Brooklyn; assistant surgeon of U. S. Volunteers during the Civil War; died at his home in Brooklyn, October 16, aged 76.

Charles E. Goldsborough (license, Adams County, Pennsylvania, 1881); surgeon of U. S. volunteers throughout the Civil War; a practitioner since 1856; one of those who crossed the continent to California in 1849; died at his home in Hunterstown, October 20, from acute gastritis, aged 78.

William A. Jones, M.D. Hahnemann Medical College, Chicago, 1883; a member of the State Medical Society of Wisconsin; for four years postmaster of Oconomowoc; died in St. Mary's Hospital, Milwaukee, October 31, from cerebral hemorrhage, a week after an operation for appendicitis, aged 56.

Edmund T. Allen, M.D. Cleveland University of Medicine and Surgery, 1881; Hahnemann Medical College, Philadelphia, 1886; a Fellow of the American Medical Association; once secretary of the Nebraska State Board of Health; died suddenly at his home in Chicago, August 17, aged 57.

William Anderson Mitchell, M.D. Yale University, New Haven, Conn., 1865; a veteran of the Civil War; since 1873 an officer of the Safe Deposit Company of New York, and at the time of his death its second vice-president; died at his home in Brooklyn, September 26, aged 71.

Frederick Eugene Wadhams, M.D. Rush Medical College, 1878; a member of the Illinois State Medical Society, and for 56 years a resident of Chicago; for several years local surgeon for the Chicago and Northwestern Railroad; died at his home in Chicago, November 1, aged 60.

William Allen Tremaine, M.D. Harvard Medical School, 1883; a member of the Maine Medical Association; of Rockport, Me., for twenty years a practitioner of Providence, R. I.; died at the Evans Memorial Hospital, Camden, Me., recently, from carcinoma of the throat, aged 60.

Oliver G. Comstock, M.D. Toledo (Ohio) Medical College, 1884; a member of the Ohio State Medical Association; formerly city physician and a member of the board of education of Toledo; died at his home in that city. October 28, from heart disease, aged 58.

William John McKay, M.D. Manitoba Medical College, Winnipeg, 1899; medical health officer of Saskatoon, Sask., who was doing postgraduate work in sanitation in London; died in University College hospital, London, August 6, from pleurisy, aged 39.

Forrest Glenmore Crowley, M.D. Yale University, New Haven, Conn., 1912; house surgeon at St. Raphael's Hospital, New Haven; died in that institution, October 8, from disease of the intestine, for which operation was performed without avail, aged 33.

Edward H. Bartlett (license, Maryland); a surgeon in the confederate service during the Civil War; once postmaster of Oakland; superintendent of schools and clerk of the school board of Garrett County; died at his home in Oakland, October 2, aged 83.

Morris Ramsey Bowie, M.D. University of Maryland, Baltimore, 1908; a Fellow of the American Medical Association and a prominent practitioner of Gunnison County, Colorado; of Somerset, Colo.; died in Los Angeles, October 21, aged 27.

Timothy Miles Leatherwood, M.D. University of Alabama, Mobile, 1891; of Tuscaloosa; a member of the Medical Association of the State of Alabama; died in Asheville, N. C., October 25, from tuberculosis, aged 50.

Edward Camplin Hill, M.D. Washington University, St. Louis, 1863; for many years a practitioner of Buchanan County, Missouri; died from heart disease in the county court room in St. Joseph, October 20, aged 76.

John W. Hudson, M.D. Memphis Hospital Medical College, 1886; University of Louisville (Ky.), 1889; for several years postmaster of Milano, Tex.; died at his home in that city, October 19, from typhoid fever, aged 68.

Oscar Eugene Harris, M.D. Medical College of Ohio, Cincinnati, 1890; of Wynne Ark., and president of the Cross County Bank; died in the Baptist Memorial Hospital, Memphis., Tenn., August 20, aged 53.

John F. Lohrs, M.D. Keokuk (Ia.) Medical College, 1896; died at his home in Highland, Wis., July 26, from the effects of a gunshot wound of the chest, self-inflicted, it is believed, with suicidal intent, aged 39.

Chester Belding Jennings, M.D. Hahnemann Medical College. Philadelphia, 1881; a member of the school board of Reading, Pa., for fifteen years; died at his home in that city October 10, from diabetes, aged 57.

John W. P. Harrod (license, Arkansas, 1905); of Olmstead, was shot and killed by the husband of a patient near Olmstead. October 10, aged 33.

Grover Cleveland Edwards, M.D. Atlanta (Ga.) School of Medicine, 1913; of St. Petersburg, Fla.; house physician at the Wesley Memorial Hospital, Atlanta; died in that institution, August 5, aged 27.

Newton S. Matthews, M.D. Medical College of Ohio, Cincinnati, 1880; a member of the Kentucky State Medical Association; died at his home in Williamstown, Ky., October 28, from heart disease, aged 62.

W. H. H. Crow (license, Missouri, 1883); a practitioner of Monroe County, Missouri, for 65 years; died at the home of his daughter in Kirksville, Mo., September 20, from cerebral hemorrhage, aged 89.

James F. Mock (license, Indiana, 1897); for thirty years a practitioner of Marion; once a representative from Madison County in the state legislature; died at his home in Marion, October 5, aged 76.

Edward Enos Hopkins, M.D. University of Buffalo, N. Y. 1906; a practitioner of Rochester until compelled to retire on account of ill health; died at his home in Honeoye Falls, October 24, aged 31.

H. K. Legge (license, Arkansas, 1903); a practitioner for more than forty years and a Confederate veteran; died at his home in Garfield, Ark., September 21, from senile debility, aged 83.

Alba G. Blanchard, M.D. Eclectic Medical Institute, Cincinnati, 1882; a member of the Illinois State Medical Society; died at his home in Creston, October 28, from diabetes, aged 65.

Elmer E. Lamb, M.D. Eclectic Medical University, Kansas City, Mo., 1911; professor of orthopedic surgery in his alma mater; died at his home in Kansas City, October 8, aged 48.

John A. Fritz, M.D. California Eclectic Medical College, Los Angeles, 1895; of San Francisco; died in the municipal tuberculosis hospital, September 26, from tuberculosis, aged 53.

Armatus S. Holland, M.D. Chicago Homeopathic Medical College, 1896; for many years a practitioner of Chicago; died at his home November 2, from cerebral hemorrhage, aged 71.

Lawrence David Hyde, M.D., Cooper Medical College, San Francisco, 1906; of Visalia, Cal.; died in the German Hospital, San Francisco, September 24, from tuberculosis, aged 31.

William Herbert Lynn, M.D. Rush Medical College, 1877; of Hastings, Neb., and at one time coroner of Adams County; died in Ingleside Hospital, October 18, from pneumonia.

John Franklin Ford, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1883; died at his home in Waggoner, Ill., August 30, from carcinoma of the pancreas, aged 61.

Leo Henry Hartzell, M.D. Jefferson Medical College, 1913; died in the Philadelphia Municipal Hospital, in which he was an intern, from scarlet fever, October 12, aged 22.

George M. Howe (license, Kansas, 1909); of Wichita, Kan., and later of Kansas City, Mo.; died in Oklahoma City, Okla., September 26, from heart disease, aged 42.

George L. Lee, M.D. College of Physicians and Surgeons, Baltimore, 1882; died at his home in Center Hall, Pa., August 7, from carcinoma of the liver, aged 60.

James Polk Fox, M.D. Chicago Medical College, 1875; for eight years United States pension examiner; died at his home in Gaylord, Mich., October 9, aged 65.

Louise Anna Kortbein, M.D. Cincinnati College of Medicine and Surgery, 1886; died at her home in Cincinnati, October 4, from cerebral hemorrhage, aged 62.

James N. Mitchell, M.D. Vanderbilt University, Nashville, Tenn., 1881; was found dead from heart disease, on his farm near Plumerville, Ark., October 3.

Harry William Hyatt, M.D. New York University, New York City, 1898; of New York City; died in St. Luke's Hospital, October 23, aged 39.

Gotthard Hirsemann, M.D. Long Island College Hospital, Brooklyn, N. Y., 1888; died at his home in Highland Mills, N. Y., October 6, aged 3.

William E. Hathawa M.D. Pulte Medical College, Cincinnati, Ohio, 1889; died a his home in Cincinnati, October 8, from nephritis, aged 68.

William P. Manaton, M.D. New York Homeopathic Medical College, New York City, 188 ; died at his home in Greenport, N. Y., August 6, aged 48.

Fred Benniman Gale, M.D. U iversity of Vermont, Burlington, 1880; died at his home in lainfield, September 21, from heart disease, aged 60.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

BAUGHN'S PELLAGRA REMEDY

A Worthless Nostrum Sold Under Fraudulent Claims

"Pellagra Cured!" This, in letters an inch high, is the title of a gaudy-covered booklet sent out by "Dr. G. P. Baughn—American Compounding Co., Jasper, Alabama." The "cure" in this instance is "Baughn's Pellagra Remedy." The greater part of the booklet is devoted to testimonials. The balance of it is written in the most approved "scare" style and is to the tenor that 20,000 people are suffering from pellagra and that the only hope for the victims of the "grim specter, stalking unseen up and down the land, touching with the icy hand of death the young child *playing in the sun*, the devoted mother *crooning o'er her babe*, the father *toiling in the field*"—is "Baughn's Pellagra Remedy"!

This book is apparently intended to convince the public that every vague ache and pain is a symptom of pellagra. "How," asks Baughn, "may you recognize this monster before his grasp on your body makes all your struggles futile?" The answer is forthcoming:

> "Have you a feeling of nervous exhaustion and lassitude?
> "Have you unusual bowel disturbance and diarrhoea?
> "Have you pains and aches for which there seem no cause?
> "Have you headaches and vertigo difficult to explain?"

If you have any of these, the inference is that the "grim specter," pellagra, has you in its grasp! Horror is piled on horror in the most approved "patent medicine" style, reaching as a grand climax a description of "the last stages" and closing with the peroration:

> "*And the last stage, till now*—the MAD HOUSE and DEATH."

Of course the escape from this catastrophe is Baughn's nostrum.

> "Like a guardian spirit my remedy stands between you and this hitherto unconquered disease—thrusting off its hideous grasp, healing your body and filling you again with the JOY of living. Even the most stubborn cases yield readily to this miraculous cure. I've cured to stay cured those whom regular physicians had given up to die."

Like every quack—if we are to believe their statements—Baughn "searched and searched" until he "had found in nature's laboratory the balm that heals"! And now: "I offer the cure to the world"—price $10.

"Dr." Baughn, by inference, claims to be a physician. "My knowledge of medicine," says he, "enables me to diagnose those conditions [of pellagra] accurately." As is often the case, the banks are used as an asset to quackery. In the Baughn booklet the Central Bank and Trust Company of Jasper testifies: "We are acquainted with Mr. G. P. Baughn of the American Compound Company and know him to be thoroughly reliable." It says further, "We do not hesitate to say that he, as well as all other members of said company, will carry out any contract they make." The Central Bank and Trust Company ought to know, as its president, H. W. Cranford, is apparently a co-partner in Baughn's quackery, his name being given as vice-president of the American Compounding Company. The bank's vice-president, W. C. Clark, is president of the American Compounding Company—truly a beautiful combination!

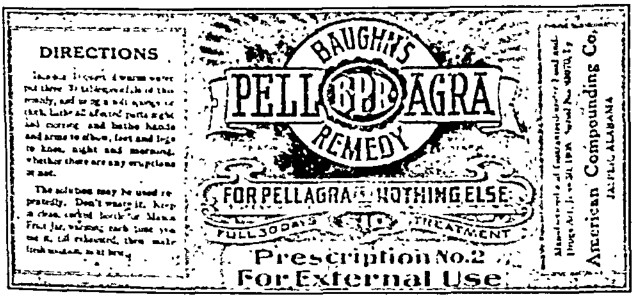
Letters sent out as late as July, 1913, give the following as officers and directors of the American Compounding Company:

W. C. Clark, president and director.
H. W. Cranford, vice-president and director.
J. H. Bankhead, Jr., secretary, treasurer and director.
A. F. Fite, director.
G. P. Baughn, director.

The later stationery has, in addition to these names, that of Dr. A. L. Hendon, "Medical Director." According to our records, A. L. Hendon is not a graduate of any medical college, but seems to be licensed to practice medicine in Alabama. Needless to say he is not a Fellow of the American Medical Association or a member of his local society. So far as G. P. Baughn is concerned, in spite of the fact that he terms himself "doctor," claims to be able to diagnose diseases and to have studied medicine, our records—and they are exceedingly complete—fail to show that any man of this name was ever graduated by a medical college or licensed to practice medicine. Certain it is that G. P. Baughn holds no license to practice medicine in the state of Alabama.

A ten-dollar "treatment" of Baughn's Pellagra Remedy was sent to the American Medical Association by the State Health Officer of Alabama, Dr. W. H. Sanders, who asked that the stuff might be analyzed and the public given the information. Dr. Sanders reported that the sale of the "cure" in pellagra-ridden districts was hindering the efforts of the medical profession in its campaign of sanitary enlightenment, looking to the prevention of pellagra. As in all such cases, the exploitation of worthless "cures" causes the general public to take the attitude that it is unnecessary to change one's method of living or subject one's self to minor inconveniences to prevent a disease that can be "positively cured" by Dr. Quack's Specific.

The nostrum sent in by Dr. Sanders was in powder form and in two bottles. One bottle was labeled "Prescription No. 1, For Internal Use"; the other "Prescription No. 2, For External Use." "Prescription No. 1" consisted of black powder in capsules; "Prescription No. 2" was a coarse, mustard-colored powder, loose in the bottle. The stuff was analyzed in the Association's laboratory and the black powder in the capsules was found to have—in addition to small particles of straw and "dirt"—essentially the following composition:



DIRECTIONS

BAUGHN'S PELLAGRA REMEDY

BPR

FOR PELLAGRA & NOTHING ELSE

FULL 30 DAYS TREATMENT

Prescription No. 2
For External Use

American Compounding Co.,
JASPER, ALABAMA

Fig. 1.—Photographic reproduction of label on one of the bottles of Baughn's "cure" for pellagra.

Quinin Sulphate	2 per cent.
Charcoal	13 per cent.
Impure Iron Sulphate	85 per cent.

"Prescription No. 2" also contained particles of "dirt" and straw and was found to consist, approximately, of:

Common Salt	25 per cent.
Monsel's Salt (Basic Iron Sulphate)	75 per cent.

The chemist's report in further detail follows:

CHEMIST'S REPORT

The specimens of Baughn's Pellagra Remedy, submitted to the Association's laboratory for examination, were contained in two separate bottles. One bottle contained a number of capsules and was labeled: "For Pellagra and Nothing Else—Full 30 days' treatment—$10.00—Prescription No. 1, For Internal Use, Manufactured and Guaranteed Under Food and Drugs Act, June 30, 1906. Serial No. 48970, by American Compounding Co., Jasper Alabama," and contained capsules. The other bottle contained a yellow powder and was labeled as above, except for the modification "Prescription No. 2, For External Use."

The capsules of "Prescription No. 1" contained a black and very poorly mixed powder along with particles of straw and "dirt." The average weight of the contents was 0.50 gram (about 7½ grains) to each capsule. As nearly a uniform sample as possible was analyzed with the following results:

Qualitatively the presence of charcoal, iron, [traces of aluminum and magnesium] quinin and sulphate was demonstrated. The iron was present in both ferric and ferrous forms. The following quantitative composition was found:

Carbon	12.5 per cent.
Iron (Fe)	25.9 per cent.
Sulphate (SO_4)	43.5 per cent.
Quinin	1.7 per cent.
Water (Loss at 120 C.)	3.3 per cent.
Alumina (Al_2O_3)	0.1 per cent.
Undetermined	13.0 per cent.

From the examination it is concluded that Baughn's Pellagra Remedy, "Prescription No. 1" consists essentially of charcoal 13 per cent., quinin sulphate 2 per cent. and impure iron sulphate, chiefly basic ferric sulphate, 85 per cent. Accordingly each capsule contains quinin sulphate 1/6 gr., charcoal 1 gr and impure, iron sulphate (basic) 6½ grs.

Examination of the "Prescription No. 2, For External Use," showed the yellow powder not to be readily soluble in water but readily soluble in acidulated water. The powder was not uniform in composition and from it crystals and even lumps (later proved to be sodium chlorid) could readily be separated mechanically as well as particles of straw and "dirt." Qualitative examination indicated the presence of iron, both in the ferrous and ferric condition, sodium, sulphate, chlorid and a small amount of a substance volatile in steam which was not identified. Quantitative determinations made on a representative sample gave:

G. P. BAUGHN, American Compounding Company, Incorporated,
Jasper, Alabama.

Fig. 2.—Quackery is profitable! Full-page newspaper advertisement of Baughn's pellagra "cure." The original was 14 inches by 20 inches in size.

Iron (Fe)	21.5 per cent.
Sulphate (SO_4)	41.4 per cent.
Sodium Chlorid (NaCl) (calculated from chlorid determination)	26.6 per cent.
Undetermined	10.5 per cent.

From the physical properties of the powder and from the analytical data obtained it is concluded that Baughn's Pellagra Remedy, "Prescription No. 2, For External Use," consists approximately of sodium chlorid (common salt), one part, and basic iron sulphate three parts.

The label on Baughn's Pellagra Remedy, "Prescription No. 2," directs that three tablespoonfuls be shaken with one quart of warm water and the solution so obtained be used. To determine the composition of the solution so obtained, three tablespoonfuls (about 55 gm.) were well shaken with one quart of warm water and this allowed to stand for three days. Examination of the supernatant solution showed each 100 c.c. to contain approximately, 1.4 gm. of sodium chlorid and 2.7 gm. of basic ferric sulphate (Monsel's salt). This is equivalent to about 7 grains of common salt and about 14 grains of Monsel's salt to each fluidounce.

And this is the marvelous "cure" for which Baughn claims to have "searched and searched" and finally "found in nature's laboratory!" This is the stuff that, according to Baughn, is "the balm that heals—the antidote for the poison that weakens and deadens body and intellect alike." This, a mixture of charcoal, common salt, iron sulphate and a dash of quinin—not to mention the straw and "dirt"—is what Baughn is selling at $10 a "treatment" to the unfortunate sufferers from pellagra.

There are many disreputable ways of making money, but we know of none so mean, so heartless, so devoid of common decency as that employed by the nostrum fakers. It is they who feed, carrion-like, on the fears of suffering humanity. To those stricken with a well-nigh incurable disease, they hold out the hope of a "sure cure" in the form of worse than worthless nostrums. To this class belong Baughn and his co-partners in fraud. Baughn's remedy is utterly impotent to cure pellagra. In hampering the efforts of sanitary officers to stamp out the conditions that favor the spread of pellagra, Baughn is guilty of a social and economic crime; in frightening those who have not the disease into the belief that they are suffering from it, Baughn but follows the villainous tactics of the "patent medicine" fakers; in selling as a "cure" his worthless stuff to those who have the disease, he perpetrates a heartless fraud.

WATERBURY'S COMPOUND ONCE MORE

Most of our readers will remember what The Journal has published about a product that used to be sold as "Waterbury's Metabolized Cod-Liver Oil Compound." Briefly, it was shown by a report of the Council on Pharmacy and Chemistry and a contribution from the Association's laboratory, that this "Cod-Liver Oil Compound" contained practically no cod-liver oil! Later the federal government declared the stuff misbranded.

The product is now sold under the name "Waterbury's Compound." It was recently stated in this department that "Waterbury's Compound" was one of the proprietary preparations advertised both in "display" form and also in the form of an "original article," in the *Army and Navy Medical Record* —a fraudulent publication that offered its editorial pages for sale. Physicians are now receiving from the Waterbury Chemical Company, a reprint of what purports to be an editorial from the *Army and Navy Medical Record* entitled, "One of America's Most Valuable Preparations." The preparation, of course, is "Waterbury's Compound." The company in sending out this reprint also reproduces on the reverse side the title-heading of the *Army and Navy Medical Record.* All of which goes to show that some concerns not only do not mind being found in bad company, but seem proud of it. By the way, we wonder whether those physicians who are still prescribing this nostrum think they are prescribing a preparation containing cod-liver oil!

Tentative Conclusions Concerning Pellagra.—After two years of research the Thompson-McFadden pellagra commission in South Carolina, sums up its findings as follows: "1. The supposition that ingestion of good or spoiled maize is the essential cause of pellagra is not supported by our study. 2. Pellagra is, in all probability, a specific infectious disease communicable by means at present unknown. 3. We have discovered no evidence incriminating Buffalo gnats in the causation of pellagra. If it is distributed by a blood-sucking insect, the stable-fly would appear to be the most probable carrier. 4. We are inclined to regard intimate association in the household and the contamination of food with the excretions of pellagrins as possible modes of distribution of the disease. 5. No specific cause of pellagra has been recognized."

Correspondence

The Central Health Institute

To the Editor:—It has been brought to my attention that in a recent number of The Journal I was mentioned as one of the incorporators of the "Central Health Institute," an institution which has carried on considerable advertising. The fact as stated is correct, but the inference easily deduced is entirely wrong, for I withdrew from the corporation within one month after it was incorporated. The "Central Health Institute" was incorporated with the intention of establishing an ethical institute of physiologic therapeutics and later a sanatorium. This institute then was located in the Methodist Book Concern Building, which does not rent to advertising concerns. Dr. Livingston, who had just graduated from the medical college, was introduced to me by the president of the college, and it was on his recommendation that I entered into the work. It took less than a month to demonstrate that Dr. Livingston's ideas and mine were entirely different, so both Dr. Lambert and I withdrew from the institution and Dr. Livingston and the "Central Health Institute" moved to a different location, while I retained the offices in the Methodist Book Concern Building. I attach a copy of documentary proof of my statements. In justice to Dr. Lambert and myself I ask you to publish this letter in The Journal, from which the misunderstanding started and to remove our names from all copies of the pamphlet [reprint] sent out in the future.

Edith B. Lowry, M.D., St. Charles, Ill.

[Comment.—We are pleased to publish this letter in justice to Dr. Lowry. The Dr. Livingston referred to, Margaret M. Livingston, was graduated in 1909 by Bennett Medical College, Chicago, whose president at that time, as now, was Dr. John Dill Robertson.—Ed.]

No Optical Goods Concession at the Panama-Pacific International Exposition

To the Editor:—In The Journal for Oct. 11, 1913, p. 1382, there is an editorial headed "Spectacles and the Panama Exposition," in which you comment rather bitterly on the proposed sale of an optical goods concession at the Panama-Pacific International Exposition. You base your comments on the assumption that any concession for the sale of optical goods must necessarily be on the same plane as one for the sale of peanuts. This assumption is utterly unfounded. It is, moreover, an injustice aggravated by the fact that the exposition directorate took special care to guard against the very dangers which you assume must necessarily arise.

It may not be known to you that the laws governing the practice of optometry in California are exceptionally rigid. No man in California is allowed to sell spectacles or eyeglasses unless he is duly qualified and certified. A spectacle-selling concession in the exposition grounds would be, and must be, conducted on precisely the same professional plane as it would be if on Market Street, San Francisco, or State Street, Chicago. In fact it would, if anything, be on a higher plane, for in addition to the statutory protection of the state of California the exposition directorate had surrounded this particular concession with several other safeguards. These were so rigid that one prominent member of the American Optical Association complained that no optometrist could possibly make any money under such restrictions. He endeavored to have the regulations modified in order that he, himself, might become a bidder for the concession, but was refused. Please consider this in answer to the accusation that the exposition regarded only the commercial side of the matter.

The citizens of California intend to build and to conduct an exposition utterly free from any taint of graft, favoritism, extortion or uncleanliness. The safety, comfort and fair treatment of visitors stand first in all plans. This is to be the greatest exposition in history and one of which California and the nation must be proud. We take this responsibility very seriously and if you knew how hard we are trying to reach high ideals in plan and execution you would, I am sure, give us congratulations and support. But all this is beside the mark, for the optical goods concession has been withdrawn from sale and no spectacles or eye-glasses will be sold at the exposition. So the matter is pleasantly settled. But I cannot refrain from giving you the facts as they were, because your accusation of selfishness and greed *hurts*.

George Hougbberry, San Francisco,
Director, Division of Exploitation.

[Comment.—We are delighted to publish the preceding and congratulate the officials of the Panama-Pacific International Exposition on their action in this matter.—Ed.]

Should Friends of Patients be Admitted to the Operating-Room?

To the Editor:—A rather sad but unique accident occurred in my service at Harper Hospital, Detroit, October 30, which answers this question most convincingly in the negative. A friend of a patient insisted on being admitted to the operating-room. He was told that the privilege was not allowed by the rules of the hospital, but could not understand why it should be denied him. He maintained that as long as his own daughter was the nurse in charge of the case, and that the patient to be operated on was a dear friend, he surely would be able to withstand the strain of the operation without any evil effect, and after some discussion he was finally admitted. During the course of the operation this friend of the patient fainted and fell, striking his head on the mosaic floor. He bled from the nose and ears, and roentgenoscopy revealed a T fracture of the base of the skull. His condition is still critical.

Another even more disastrous accident occurred at the Kalamazoo Hospital not very long ago. In this case the patient's relative felt a feeling of faintness coming over him, and in order to rid himself of the disagreeable sensations walked over to an open window for more fresh air. He sat on the window-sill and while sitting there fainted away completely. He fell out of the window and in falling sustained a fracture of a cervical vertebra which proved fatal.

I cite these two cases just to show what evil results may follow the unnecessary practice of admitting friends of patients to the operating-room.

Angus McLean, M.D., Detroit.

Method of Sterilizing Rubber Gloves

To the Editor:—For three years I have been using the method of glove sterilization criticized by Dr. McDonald (The Journal, Nov. 8, 1913, p. 1735). Undoubtedly gloves covered with "blood, pus, serum or soap" would be impervious to the action of cyanid or alcohol; but in soap and hot water we have a very active agent for the removal of these "organic substances" from the smooth surface of the rubber glove, and most certainly the gloves are to be washed and rinsed, as stated in my article. Alcohol is conceded by most, if not all, authorities to be a most effective germicidal agent. Many of our most famous surgeons use no other method of hand sterilization than scrubbing with soap and water followed by alcohol.

The gloves made clean by soap and water and sterilized by alcohol are protected from subsequent infection by the talc-cyanid powder. It was not my intention to recommend these gloves for all purposes, but for obstetric work; and surely, when infection is known to exist prior to the use of the gloves they would be boiled subsequently before being treated with the cyanid solution. Theoretically they may not be sterile, but practically they surely seem to be. Theoretically gloves must be boiled for thirty minutes under a pressure of 15 pounds to be sterile, but practically how many men do boil their gloves under pressure, and for thirty minutes? My method is not ideal, but it is much more safe than the ungloved hand hurriedly washed, dipped into compound solution of cresol and used, which is by no means a rare occurrence among general practitioners in obstetric work.

Ray Ernest Smith, M.D., Rutland, Vt.

The Unscientific Prescribing of Complex Pharmacopeial Mixtures

To the Editor:—Dr. Osborne's criticism and condemnation of certain pharmacopeial mixtures (The Journal, Oct. 4, 1913, p. 1289) will undoubtedly be appreciated by the thoughtful and careful physician. If it is unscientific to prescribe ready-made patented or proprietary remedies when their exact composition is unknown to us, why is it not equally unscientific to use complex official preparations, some of the ingredients of which we generally do not remember? The fact that we usually know the therapeutic use of the preparation as a whole and its dose is not enough to justify our prescribing it. Every dose of medicine which the doctor gives his patient to swallow should have all its ingredients carefully considered and passed on by the prescriber. This can hardly be done with complex ready-made preparations, as the doctor seldom remembers their exact composition.

Just the other day, while in a drug-store in my neighborhood, I saw a prescription from a regular physician in good standing calling for paregoric, brown mixture, glycerin and water. The druggist told me that he called up the doctor on the telephone and informed him that brown mixture (mistura glycyrrhizæ composita) contains paregoric (camphorated tincture of opium) as one of its ingredients, and that glycerin enters into the composition of paregoric. The doctor thanked him and authorized him to leave out the paregoric and glycerin and dispense only the brown mixture and water.

Such errors we make daily just because it is impossible for the average practitioner to remember the composition of these mixtures.

Dr. Osborne's criticism well deserves the closest attention of every doctor. L. Buckle, Ph.G., M.D., New York.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

OPEN-AIR TREATMENT AND THE FLUELESS HEATER

To the Editor:—I may be, as you state in your reply to my note on "The Open-Air Treatment" and "The Flueless Gas-Heater" editorials (The Journal, Nov. 1, 1913, p. 1649), "evidently unfamiliar with the literature" when I say that the experiments are too few to permit "definite conclusions to be safely drawn on a subject which concerns the health of millions of people"; but I am not the only occupant of that conspicuous position.

When you wrote in the editorial on "The Open-Air Treatment" (The Journal, Oct. 11, 1913, p. 1378) the words "is wholly in accord with recent experimentation," you evidently were unfamiliar with the literature on the subject. Permit me to add to the list of authorities you so kindly furnished that of Yandell Henderson (*Tr. Fifteenth Internat. Cong. Hygiene and Demography*, vii, 622). And now that your attention has been directed to Henderson, it will be in order for you to dispose of him, or rewrite the phrase "wholly in accord" to correspond to the facts; for "wholly" means "entirely," and Henderson produces facts that are not "wholly in accord."

That I had good grounds for the statement that the experiments are altogether too few to permit definite conclusions to be drawn on a subject which concerns the health of millions of people, and that the subject of ventilation is still open, and that more facts should be observed and presented for consideration before we can draw definite conclusions, allow me to quote from Henderson: "We have really" he writes, "at the present time no adequate scientific explanation for the health-stimulating properties of fresh air and the health-destroying influence of bad ventilation." He summarizes the literature of the subject, including the heat-block conclusion, and asks, "Is this explanation satisfactory?" and adds, "I must confess for me it is not. From the standpoint of hygiene, it is practically proved. From the standpoint of physiology, however, the proof offered by Hill and Flügge merely opens up a new question." In conclusion he says, "The subject needs investigating along new lines rather than a rehearsal of old data." Thus, according to Henderson the conclusions of Flügge furnish no adequate scientific explanation, and I had good grounds for the statement that the subject of ventilation is still open and that more facts should be observed and presented before we can draw definite conclusions.

This is also in accord with Winslow (N. A. S. Report, 1911, p. 784) when he states that "extended studies of actual conditions in relation to their effect on physical and mental efficiency can alone furnish a sound basis for such standards as we should like to possess."

The conclusions based on the experiments of Hill and Flügge have furnished a good working hypothesis and have been of value in satisfying the hygienists, but it is very probable that in a few years it will resemble one column, and not a complete edifice, or else perhaps a bird's nest from which the birds have flown.

John B. Todd, M.D., Syracuse, N. Y.

Answer.—In reply we may say:

1. At the time the editorial in question was written the *Transactions of the Fifteenth International Congress on Hygiene and Demography* had not been published. There was therefore a reason for being "unfamiliar" with the article in question.

2. Professor Henderson's interesting paper to which our correspondent refers does not contain new experimental data, but is simply a discussion of the physiologic side of ventilation.

3. We would especially call our correspondent's attention to the fact that the article he quotes does not advocate the view that the effects of bad ventilation are due to chemical impurities in the air or to lack of oxygen. On the contrary, starting with the thesis, which "is wholly in accord with recent experimentation," that high temperature, moisture content and air-stagnation are the factors whose influence in ventilation have thus far been demonstrated, Henderson discusses the precise nature of the physiologic reactions to these conditions on the part of the organism. Briefly, his conclusion is that instead of skin conditions being responsible for all the results of bad ventilation, oxygen secretion on the part of the lungs must be taken into consideration. This is somewhat different from Hill's explanation of the physiologic response to conditions of good and bad ventilation, but it in no way touches either the point raised in our editorial of October 11 or our answer to our correspondent November 1. Henderson evidently considers that the effect of cold on the skin "is to stimulate the pulmonary epithelium to secretory activity." He continues: "Taking all of these facts into account, it is logical to conclude that the lungs are normally the seat of a more or less active process of oxygen secretion, and that the effects of warm, moist air on the skin are to inhibit this process in the lungs." Note that "cold" and "warm, moist air" are the factors mentioned.

4. Even if we were to assume that we know all about the factors concerned in ventilation—an assumption by no means justified—we should still have the problem of the way in which these factors act on the human body. This is the real theme of Henderson's article; it is quite true, as he states, that "the proof offered by Hill and Flügge merely opens up a new problem." In scientific investigation a problem "solved" always reveals others in need of solution. The point we attempted to emphasize in our editorial was that there is no evidence that the effect of bad ventilation is due to chemical impurities, but that the observed effects can be largely if not wholly explained by high temperature, high humidity and air-stagnation and that the action of these factors on the human organism may in turn be accounted for on rational physiologic grounds. Our correspondent seems to have misunderstood completely the tenor both of the criticized editorial and of Henderson's article. We recommend a careful rereading of both.

LITERATURE ON PSYCHOLOGY AND PSYCHOTHERAPY

To the Editor:—Please refer me to recent works on philosophic and scientific explorations, investigations and speculations of the occult sciences, the subconscious mind, psychotherapy, dreams, etc.

E. F. Wiederanders, M.D., Estancia, N. Mex.

Answer.—Following are some useful works in this broad field:

Tuckey: Psychotherapeutics, G. P. Putnam's Sons, 29 West Twenty-Third Street, New York. $3.
Forel: Hypnotism, or Suggestion and Psychotherapy, translated by H. W. Armit, Rebmar Company, 1123 Broadway, New York.

REGULIN

To the Editor:—Will you kindly let me know what Regulin is? Enclosed is literature telling what it is, but there is so much left unsaid that I will be grateful for more information.

F. M. R., Monticello, Iowa.

Answer.—Regulin is agar-agar (N. N. R., 1913, p. 20) to which some cascara preparation has been added. The product at one time was described in the Appendix to New and Nonofficial Remedies as follows:

> A mixture of agar-agar in a dry form with extract of cascara sagrada representing 15 per cent. of an aqueous fluidextract of cascara sagrada.

RIMINI-BURNAM TEST FOR FORMALDEHYD IN URINE

To the Editor:—Please describe the Rimini-Burnam test for formaldehyd in the urine. J. W. Shuman, M.D., Sioux City, Iowa.

Answer.—The test referred to is a modification of the Rimini test by Mr. H. A. B. Dunning, and is thus described by him in the *American Journal of Pharmacy*, October, 1913:

> About 2 c.c. of urine specimen, contained in a five-inch test tube, is warmed and two drops of 0.5 per cent. solution of phenylhydrazin hydrochlorid is added, followed by 2 drops of 0.5 per cent. solution of sodium nitroprussid, the mixture being made strongly alkaline with saturated solution of sodium hydroxid. In strengths of from 1:20,000 to 1:50,000 a deep-blue coloration results, changing in a few minutes to green, then yellow, or perhaps, red. In more dilute solutions the blue lasts momentarily only, and is quickly superseded by green. The blue may be made to last longer and become more distinct by adjustment of the quantities of sodium nitroprussid and phenylhydrazin hydrochlorid added, the weaker strengths requiring less nitroprussid and phenylhydrazin. In alkaline solutions phenylhydrazin gives a yellow color; therefore, if there is but a trace of formaldehyd, the depth of blue color is masked and converted into green by mixtures of colors blue and yellow.

The following method may be used to determine the quantity:

> To 5 c.c. of specimen contained in a 5-inch test-tube, add 0.1 c.c. of 15 per cent. solution of sodium hydroxid and mix well. Then add 0.1 c.c. phenylhydrazin, base, not hydrochlorid; finally add 0.7 gm. of stick sodium hydroxid and agitate for ten minutes. The strength is estimated colorimetrically by comparing with the standard solutions treated in same manner as specimen, and at the same time. It is important to remember that the several reagents must be added to specimen and standard solutions at the same time; that is, specimen and standard are treated simultaneously. Standard solutions of formaldehyd may be prepared by accurately diluting an assayed specimen to the strength of 1:50,000, 1:100,000, 1:200,000, etc.

PETROLEUM POISONING—CARBON MONOXID POISONING

To the Editor:—1. Please give symptoms and treatment of poisoning by inhaling the fumes of gasoline.

2. Give symptoms and treatment of carbon monoxid poisoning.

E. S. Caster, M.D., Solomons, Md.

Answer.—1. The general symptoms of petroleum (gasoline) poisoning consist in headache, dizziness, accelerated heart-action, labored respiration, collapse, stupor, unconsciousness and, more rarely, convulsions; sometimes there is a rise of temperature. Drowsiness is a prominent symptom. Unconsciousness has come on in from ten to fifteen minutes after the swallowing of less than half an ounce of benzin. In cases of collapse, warm baths with cold affusions are recommended; the usual respiratory and cardiac stimulants are also indicated.

2. A description of the symptoms and treatment of monoxid poisoning would occupy more space than can be given to it. We refer the reader to an article on illuminating-gas poisoning in the Handbook of Therapy; page 408. This article also appeared in The Journal, Feb. 6, 1909, p. 473.

Medical Economics

INCOME TAX APPLIED TO PHYSICIANS

The amount of discussion in the newspapers and elsewhere has made those interested familiar with the general provisions of the income tax. Its application to physicians, however, involves some difficult problems, the working out of which will have no small effect on the economic side of the practice of medicine. The general provisions of the law are well understood.

The first and most important question which will be raised by the application of this law to physicians is, What is a physician's income? In the case of physicians or surgeons employed on a salary by life-insurance companies, railways and other industrial organizations, the question is as easily determined as in that of any other class of salaried employees. The great bulk of physicians, however, have an income made up of fees received from patients for services rendered, the sums being large in number and relatively small in amount.

It has been customary for a physician to regard his gross receipts for the year as his income. The inaccuracy of such a supposition, and the injustice of taxing a physician on his gross receipts, is self-evident. Out of the entire amount of money received during the year, the physician or surgeon has to pay the expenses of his business. His gross receipts no more constitute his income than the gross receipts of a dry-goods store constitute the income of the proprietor. Out of his gross receipts a physician has to pay for his office, telephone, office girl, stenographer, instruments, books, professional journals, drugs, dressings, and all the material needed for his work, as well as for the maintenance of horses, carriages, automobiles or other means of conveyance. Clearly, a physician's income is the difference between his gross receipts and the cost of operating his business, or the amount that he has left for himself and his family after paying all his necessary professional expenses.

In the case of surgeons in large cities or specialists doing an exclusive office practice, it will be comparatively easy to separate the necessary business expenses from personal expenses. It will be necessary only to keep a separate account of all expenses connected with one's office, and to deduct this amount from the gross receipts. It is doubtful, however, whether even these elementary bookkeeping methods are being followed by the majority of physicians under such conditions. A careful inquiry would probably reveal the fact that many of our most successful specialists and surgeons would be unable to tell, offhand, how much it costs them to carry on the business side of their work during the year. Such a separation of business and personal expenses will become necessary under the law in order to determine the real income of such physicians.

The law provides for the deduction of "necessary expenses for carrying on any business." Obviously the difficulty will lie in determining what these necessary expenses are. When the case of the average general practitioner in the small city, town or country district is considered, however, the difficulties multiply. In many cases the only form of bookkeeping followed by physicians has been a personal running account with each patient or family. Services have been charged against the patient and payments have been credited. No attempt has been made to balance the books annually, to charge off bad accounts, to estimate the value of standing accounts, or to arrive at any definite figures as to the cost of doing business. Outside of the larger cities the majority of physicians have their offices in their homes. No attempt is made to separate office rent or office expenses from general living expenses. Heat, light, telephone and other necessities for professional work are also utilized for personal and family purposes. Drugs, dressings and other supplies are often purchased at the local drug-store, where a running account is carried, and where many articles for family use are purchased at the same time. Medical books are purchased and journals subscribed for, without any thought of the cost being a professional, and not a personal expense. Membership in medical societies is not recognized as anything but a personal relation, although in many cases it carries with it subscriptions to medical journals and is maintained for purely professional reasons. Horses, carriages or automobiles are used indiscriminately by the doctor for professional purposes and by himself or his family for social purposes and recreation. It is probably safe to say that the plan followed by the majority of physicians in the United States is to collect as large a percentage of their bills as possible, pay out of their available funds their professional and personal expenses and the expenses of their families without any effort at discrimination, and to regard any surplus which may remain as profit for investment or increased expenditures.

In the case of unmarried physicians whose gross receipts for the year amount to less than $3,000, or married physicians whose gross receipts are less than $4,000 there will, of course, be no difficulty. They will clearly come under the exemption clause. The limited number of physicians practicing surgery or any exclusive office specialty in large cities, who have systematized their work on a business basis, will also offer no difficulty. They can readily show the amount of their operating expenses and the balance remaining which will be subject to the income tax. The difficulty will arise in the case of the large number of physicians who have hitherto paid no attention to the details of expenses, and who will be incapable, without a marked change in their business methods, of separating their business and professional from their personal expenses. When this is attempted, some interesting questions will arise. For instance, should the entire cost of operating an automobile be regarded as a professional expense? It is probably true that the majority of physicians would not run an automobile were one not absolutely indispensable for present-day professional work. On the other hand, the machine is used, not only for work, but also for recreation by the physician and members of his family. How would it be possible to apportion the amount of time during the year spent in using an automobile for business and that spent in using it for pleasure?

In the same way difficulty will arise regarding office help and assistance. A physician having his office in his home has attendants who are partly professional and partly personal. A maid, for instance, who acts as attendant in the waiting-room during the doctor's office hours may be employed with domestic duties at other times. The telephone is certainly a professional necessity, and yet it is constantly used for personal and social purposes. The physician is different from any other professional man in that, in the majority of cases, his home is his place of business. The teacher has all of his equipment furnished him. The lawyer, even in small towns, hardly ever has his office in his house. The minister has little, if any, professional expenses. The business man has his place of business entirely separate, and the bookkeeping system which has been forced on him makes it easy for him to separate his business expenses from those of his home. But the physician has, for generations, carried on his work in his home. His professional and personal expenses have never before been separated.

In addition to determining what their incomes are, physicians will learn for the first time, owing to the necessity of more carefully kept accounts, what are the rewards of the practice of medicine. The ratio between expenses and profits in the practice of medicine will be learned. If it should be shown, for instance, that even in the case of a physician collecting a gross income of $10,000 a year, the net proceeds to the physician after all his expenses were paid was only $5,000, it would be evident that $5,000 and not $10,000 was his income and that in order to have $1 to spend he would have to earn $2. If it should appear that the physician collecting $4,000 a year in the small town had more money to show for his work at the end of the year than the physician in the large city collecting twice that amount, but paying out more than twice as much in expenses, then as a business proposition the advantages of country over city practice would be demonstrated. Many equally interesting and important deductions can be thought of.

The most important result of the application of this law to the medical profession, however, will be the necessity on the part of physicians of more accurate methods of bookkeeping, and more carefully kept accounts. It has often been observed that one of the most effective ways to make a man economical and thrifty is to require him to keep an accurate account of all the money which he pays out and the purposes for which it is paid. The majority of physicians to-day probably have no idea of the amount of their gross annual expenses, probably many do not even know their gross annual receipts. If compelled to keep an accurate record of all receipts and expenditures, and to draw up a balance sheet each year, the result would inevitably be greater economy in their business methods, more careful attention to business details, and, in the end, probably greater thrift and larger bank accounts. In the meantime, however, through the enforcement of the Underwood law, physicians may obtain some exceedingly interesting information regarding the economics of the medical profession, and their own financial standing.

MEDICAL INSURANCE IN GERMANY

An industrial insurance act, in the form of an amendment to the original act, but in reality practically a new law, will go into force in Germany on Jan. 1, 1914. While industrial insurance in Germany is of earlier origin than in England, apparently the government has not profited by the experience of Lloyd George in attempting to enforce the British insurance act, and has formulated the new German law without any reference to or consultation with the physicians who are to administer it. The new law leaves the classification of insurance the same as the old, namely, accidents, sickness, and invalid and old-age pensions, but adds a fourth classification in the form of provisions for widows and children of insured persons. The original act was designated as the Workmen's Insurance Act. This title is no longer applicable, as the new law greatly increases the beneficiaries, and takes in persons in the middle walks of life besides workmen. Under the old law the limit was $500 a year. All persons earning less than this amount were required to insure themselves under the provision of the act. The limit is now $600. Hereafter all workmen, domestic servants and all who contract to work for employers, whether occupied in shops or factories or their own homes, are compelled to take insurance under the law, even if their income exceeds $600, provided it does not exceed $1,250 per annum. In addition, all technical workers, schoolteachers, tutors, foremen, shop workers, and others whose income does not exceed $600 a year are required to insure themselves, while voluntary subscribers among independent workers and small landowners are permitted, in case their income does not exceed $750 a year. This extension brings under the provisions of the act not only the laboring classes, but also a very large proportion of the official and middle classes. It is estimated that the thirteen million persons insured under the old law will be increased to over twenty-two million, without including the voluntary beneficiaries.

So comprehensive is the new law that it is estimated that in some districts from 92 to 95 per cent. of the entire population will be insured. The effect of this on the private practice of medicine will, of course, be most marked. According to the *British Medical Journal,* the official bodies entrusted with the enforcement of the act in Germany correspond closely to the friendly societies and sick clubs in England. As these organizations are to be charged with the administration of the new law, the government has laid down conditions for their reorganization, and has provided that the members be divided into two groups, the city insurance societies and the rural insurance societies. In the first are included skilled workmen, tradesmen, officials coming under the operation of the law, and others. In the second class are included farm laborers, home workers and domestic servants. The small organizations under which the act has been administered heretofore will be replaced by a single organization, divided into two classes, as indicated above, with a total membership of between 400,000 and 500,000. This body will administer the insurance act for the twenty-two million of persons affected.

The same questions have evidently arisen in Germany as in England. The right of the insured to choose physicians has been one of the questions most heatedly discussed. Heretofore, the small local societies have had the right to adopt either one of two systems. Under one, any local physician was entitled to have his name enrolled as a physician on the society's books, and any member had the right to choose any physician so registered. Under the other system, the local society could appoint a certain number of physicians, and members were limited in their choice to those so chosen. German physicians have generally favored the free choice of physicians by patients, while the societies have favored the limited list. Under the new law both systems are retained; but it is probable that the new method of organization of the workingmen's societies will result in the establishment of controlling boards, composed of equal numbers of society members and physicians, in whom the right to appoint physicians will be lodged. The annual per capita fee of $1.20 per patient per year will probably not be increased.

The enactment of this new law in Germany and its application to a greatly increased and nearly doubled number of persons, and the enactment of the national insurance law in England, are significant indications of the direction in which the practice of medicine is developing. It is of the utmost importance that American physicians know the facts regarding these efforts in other countries to secure under governmental supervision insurance against illness, accident and old age. How soon this matter will be a live issue in this country, it is difficult to say. That it will sooner or later be an important question in some form or other admits of little doubt.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

DELAWARE: State Society and Homeopathic, Dover and Wilmington, Dec. 9-11. Secretary of the Medical Council, Dr. Henry W. Briggs, 1026 Jackson St., Wilmington.

KENTUCKY: Armory, Louisville, Dec. 11-13. Sec., Dr. J. N. McCormack, Bowling Green.

MARYLAND: Regular, 1211 Cathedral St., Baltimore, Dec. 9. Sec., Dr. J. McP. Scott, Hagerstown.

OHIO: Columbus, Dec. 9-11. Sec., Dr. Geo. H. Matson, State House.

PENNSYLVANIA: Philadelphia, Dec. 2-4. Sec., Mr. Nathan C. Schaeffer, Harrisburg.

VIRGINIA: Richmond, Dec. 16-19. Sec., Dr. Herbert Old, Norfolk.

Michigan Reciprocity Report

Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine, reports that from July 21 to October 16, 1913, 10 candidates were licensed through reciprocity. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
George Washington University	(1906)	Maryland
College of Physicians and Surgeons, Chicago	(1910)	Illinois
Northwestern University	(1911)	Illinois
Indiana University	(1911)	Indiana
College of Physicians and Surgeons, Baltimore	(1911)	W. Virginia
University and Bellevue Hospital Medical College	(1911)	New York
Cleveland-Pulte Medical College	(1912)	Ohio
Western Reserve University	(1911)	Ohio
University of Pittsburgh	(1908)	Penna.
Marquette University	(1909)	Wisconsin

Montana October Report

Dr. William C. Riddell, secretary of the Board of Medical Examiners of Montana, reports the written examination held at Helena, Oct. 7-9, 1913. The number of subjects examined was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 30, of whom 21 passed and 9 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Bennett Medical College	(1912) 78.6,	82.9
Hahnemann Med. Coll. and Hospital of Chicago	(1902)	80
Northwestern University Medical School	(1884)	77.5
Rush Medical College	(1913)	82.6
State University of Iowa College of Medicine	(1907)	79.5
College of Physicians and Surgeons, Baltimore	(1911)	78.2
Johns Hopkins Medical School	(1908)	83.7
Detroit College of Medicinie	(1904)	78.8
University of Michigan, Department of Medicine and Surgery	(1906)	84.7
St. Lovis Univ., School of Medicinie (1908) 80.8;	(1912)	83.2
John A. Creighton Medical College	(1912) 78.3,	84.2
Dartmouth Medical School	(1911)	79
Albany Medical College	(1906)	76.7
Starling Medical College	(1898)	78.5
Jefferson Medical College (1907) 81.4;	(1912)	77.6
Marquette University (1911) 77.8;	(1913)	77.8

FAILED

PHYSIOLOGY, PATHOLOGY, BACTERIOLOGY

1. Discuss the evils which may follow the presence of adenoids in the posterior nares. 2. Given a case of pernicious anemia, describe the microscopic blood-picture contrasting this picture with that of normal blood, and state the effect of this disease on the normal functions of the blood. 3. Name three most usual causes of death of bone; describe the processes of death of bone and the sequelae of such condition. 4. Given a case of diphtheria, describe the local lesion, give the laboratory methods of verifying your diagnosis, and when as a sequela the heart becomes affected, show how the normal functions of this organ are interfered with. 5. Discuss hyaline, granular and fatty casts; (a) as to the local conditions usually present with each variety; (b) as to the impairment of the normal functions of the kidney in each condition. 6. Given an acute case of peritonitis, (a) state how the toxins are absorbed; (b) why the Fowler (sitting) position and enteroclysis are rational procedures. 7. In case of chronic alcoholism state the pathological changes which may take place in the liver and show how these changes interfere with the normal functions of the liver. Contrast pathological changes of advanced syphilis of liver. 8. In carcinoma of the cervix name the most common variety; describe the gross and microscopic appearance and describe the methods and avenues of extension. 9. Describe the lesions, outline the laboratory technic of demonstrating the causes of purulent perforative otitis and show the possible sources of infection and dissemination. 10. In a case of acute anterior poliomyelitis (infantile paralysis) describe the local lesion and show how the normal functions of the cord are disturbed.

PHYSIOLOGICAL CHEMISTRY

1. Describe the chemical composition of blood, giving approximately the percentage amount of the various component parts. 2. What is indican? Where is it formed? By what process is it formed? Give a test for its presence in urine. 3. Name the principal waste products of the human body. By what excretory organ is each eliminated? 4. How would you determine chemically whether or not any given stain was due to human blood? 5. Where and in what form do the following chemical elements occur in the human body; 1. Iron; 2. Iodin; 3. Phosphorus; 4. Sulphur; 5. Fluorin.

DIAGNOSIS, SYMPTOMATOLOGY, MEDICAL JURISPRUDENCE AND TOXICOLOGY

1. Enumerate the symptoms and physical signs in the early stage of acute peritonitis. 2. In syphilis, differentiate. (a) Chancre from epithelioma, (b) Secondary skin lesions from the exanthamata, (c) Tertiary skin lesions from other chronic skin diseases. 3. Enumerate the symptoms of catarrhal jaundice (duodeno-cholangitis): name two other diseases of this region that may resemble it, and differentiate them from catarrhal jaundice. 4. State the name and describe the distinctive symptoms of epilepsy resulting from traumatism; how may this form be differentiated from the non-traumatic forms of epilepsy. 5. Enumerate the cardiovascular and the cerebral symptoms of arteriosclerosis and conditions that may follow. 6. Enumerate the symptoms of tetanus; (a) give the etiology, (b) method of invasion, (c) name a toxic condition with which it may be confused and differentiate them. 7. Enumerate the symptoms and describe in detail the physical signs of chronic interstitial pneumonia (fibroid pneumonia) and differentiate it from pulmonary tuberculosis. 8. Enumerate the symptoms of tartar emetic poisoning; (a) name a disease it may resemble and differentiate it, (b) name three (3) antidotes. 9. Enumerate the symptoms of opium poisoning; (a) what are the most favorable conditions for its absorption, (b) differentiate it from apoplexy and uremia. 10. (a) Describe in detail the appearance of an infant born alive at full term; (b) the appearance of an infant dead born at term; (c) the appearance of an infant having died some time before birth (d) and a method by which it is conclusive that the infant had breathed.

OBSTETRICS, GYNECOLOGY, HYGIENE AND PREVENTIVE MEDICINE

1. Given a pregnant woman (the first three months) how would you determine whether she might be suffering from abortion or from extra-uterine pregnancy; in case of abortion how would you treat the case (omit description of operations). 2. If a woman in labor should suddenly develop the symptoms of collapse or shock, name three principal causes in the uterus which may be responsible for her condition. How would you manage the case (omit description of operations)? 3. Given a woman with a posterior displaced non gravid womb, how would you distinguish it from (a) fecal matter in the rectum, (b) a small pelvic tumor? What is the most usual cause of such displacements? How would you prevent it? 4. Name three principal toxemias of pregnancy together with their symptoms. Give the treatment of any one selected. 5. If a woman consults you as to her future labor and places herself under your care, up to the time she falls into labor detail the steps you must take in order to secure her safety. (State in full tests that should be made). 6. When is the induction of premature labor justifiable. Detail its status as related to other procedures in cases of contracted pelvis. 7. Enumerate four abdominal enlargements which may be mistaken for advanced pregnancy (seven months or more) and differentiate them from such possible pregnancy. 8. Name the diseases and methods of transmission caused by (a) house fly, (b) rat, (c) mosquito, (d) bedbug, (e) tsetse fly, (f) wood tick. 9. If an analysis of water revealed the presence of nitrites or nitrates, or both, why would this indicate its unfitness for drinking purposes. How could it be rendered safe? 10. State articles of food that are advisable in the following diseases: (a) diabetes, (b) tuberculosis, (c) anemia, with reasons for the recommendations.

PRACTICE, THERAPEUTICS, MATERIA MEDICA

1. Outline the management of a case of diphtheria in a child six years old; state the important conditions to be met, with definite methods of meeting those conditions, and give reasons for the use of each remedy selected. 2. Outline the general management of a case of pneumonia in an adult; state three remedies that may be used in this condition, with definite indications for the employment of each. 3. In a case of nephritis, indicate the various conditions that must be considered; state the appropriate remedies for each condition and give definite reasons for the use of each remedy. 4. In acute endocarditis, state the ordinary causes and possible complications, outline the management and give reasons for the employment of the more usual remedies. 5. In acute gastro-intestinal catarrh outline the several indications for treatment, with definite instructions as to remedies and reasons for their use.

SURGERY, ANATOMY

1. Describe an approved method of performing vaccination; enumerate such complications as may arise and state the reasons for those possible complications. 2. In fracture of the lower end of the radius ("Colles' fracture") state (a) the usual displacement, (b) the muscles causing same, (c) the method of reduction. 3.

State, first, what you consider the favorable conditions in a patient to whom is being administered (a) sulphuric ether, (b) chloroform; second, the unfavorable or alarming conditions that might be present with either drug. 4. Name three forms of bowel obstruction; outline briefly the symptoms that are common to each; outline a surgical operation that may be required in any one form selected. 5. Describe the normal relationship of the bony landmarks at the elbow-joint; state the alterations that may occur in these landmarks in (a) anterior luxation, (b) posterior luxation, (c) fracture of the olecranon process. 6. In fracture of the neck of the femur, state the usual deformity and the anatomical explanation of the same. Describe an external test line used in diagnosis of some hip-joint conditions. Briefly outline two methods of treatment of fracture of the neck of the femur. 7. Name three forms of abscess that may occur in the vicinity of the rectal orifice; state the directions that pus may burrow if left unchecked; briefly outline the surgical treatment of two forms of abscess. 8. State two paths along which infections may reach the kidneys. State the local and constitutional symptoms of pyonephrosis. 9. If called into the country to do an appendectomy; make complete lists (a) those things that you would desire them to furnish at the house of the patient, (b) those things that you would bring with you. 10. Describe methods of treatment of patient who has been subjected to an electrical current of high voltage.

Book Notices

The Psychoneuroses and Their Treatment by Psychotherapy. By Prof. J. Dejerine, Professor of the Clinic for Nervous Diseases of the Faculty of Medicine of the University of Paris, and Dr. E. Gauckler. Authorized Translation by Smith Ely Jelliffe, M.D., Ph.D., Adjunct Professor of Diseases of the Mind and Nervous System, Post-Graduate Medical School and Hospital, New York. Cloth. Price, $4. Pp. 395. Philadelphia: J. B. Lippincott Company, 1913.

In the present conflict of opinion as to the most plausible theory concerning psychotherapeutics, the most important part of the subject, namely, the actual practice of psychotherapy, seems to have been overlooked. In other words, we hear a good deal about this or that theory of psychotherapeutics, but little or nothing is done in the way of real psychotherapeutic endeavor. The book before us represents a sincere effort on the part of its authors not only to practice psychotherapy, but also to give the reader guiding principles. A beginning was made several years ago when Dr. Smith Ely Jelliffe translated Dubois' popular book on the subject. Since then the practitioner has been eagerly awaiting a work which might furnish him with methods and results. The work under review, also translated into English by Dr. Jelliffe, embodies the principles and practice of psychotherapy as followed by Dejerine. The book is divided into three parts. The first section is devoted to a study of the symptoms which may be observed in the course of the psychoneuroses. This is a purely analytic study, in which symptoms are traced to their supposed origin and proved to depend almost entirely on mental and moral causes, with the greater emphasis on the moral. In the second division of the book, which might well be called the psychologic portion, the authors endeavor to explain the general mechanism underlying the causation and continuance of the symptoms constituting the psychoneurosis. In the third division the authors set forth the psychotherapeutic measures to be employed in the treatment of the psychoneuroses. Quite naturally we are more interested in the last portion of the book than in the preceding ones, as the distinctive features lie in its psychotherapy. Dejerine, who had ample opportunity to study the psychoneuroses, had made the discovery early in his career that the causes of hysteria and neurasthenia must lie outside the objective symptoms, since little or no success was obtained from the employment of medicinal and mechanical measures. Further, he discovered, contrary to the views expressed by Dubois, that to obtain results the treatment must not be based solely on reasoning and argument. "If reason and argument were sufficient to change one's mind," he says, "the neuropaths would find in the writings of the moralists and philosophers and spiritual advisers everything they would need to reconstruct their morale, and consequently their physical well-being; and therefore they would have no need of a psychotherapeutist." According to Dejerine, reasoning by itself is insufficient to produce cures—the emotional element is just as important, if not more so. It is the feelings or emotions—the morale—which produce beneficial results, not the mere idea; the idea never moves one unless it is accompanied by an emotional appeal which makes it acceptable to consciousness and thus brings about conviction. For this reason he deprecates the use of hypnotism and suggestion in the waking state, both of which are appeals to the subconscious, unfeeling part of human nature. In order to test his views an isolation and psychotherapeutic ward was established in his service at the Salpêtrière. Here several thousand patients who could not afford a sojourn in a sanatorium received free treatment. The results were highly satisfactory and far surpassed the author's expectations. This success he attributes entirely to the so-called moral treatment. The book is well written and conducive to original thought.

Elements of Bacteriologic Technic. A Laboratory Guide for Medical, Dental and Technical Students. By J. W. H. Eyre, M.D., M.S., F.R.S., Director of Bacteriological Department of Guy's Hospital, London, and Lecturer on Bacteriology in Medical and Dental Schools. Second Edition. Cloth. Price, $3 net. Pp. 518, with 219 illustrations. Philadelphia: W. B. Saunders Company, 1913.

This edition contains much that is new in addition to a revision of all the old matter. As a laboratory guide for students in bacteriology, however, the book is somewhat too elaborate in most of its discussions and falls short of the mark in others. For instance, the book gives twelve methods for making anaerobic cultivations and offers no discrimination as to the one to be employed. Elaborate apparatus is pictured, which for the ordinary man is absolutely useless. On the other hand, the book makes no mention whatever of methods for preparing vaccines, although it attempts to give a complete discussion on immunization. Some of the illustrations are so elementary as to be hardly worthy of the space they occupy and others so elaborate as to be useless for anyone but the specialist. As a book of reference on the subject it would seem to have some place in medical literature, but as a laboratory guide for medical, dental and technical students, which it presumes to be, it can hardly be said to fulfill its purpose.

Die Nervenpunktlehre. Von Dr. A. Cornelius, Oberstabsarzt a. D. Volume II; Neurologie und Nervenpunktlehre. Paper. Price, 7 marks. Pp. 303. Leipsic: George Thieme, 1913.

After perusing this verbose and self-laudatory volume the reader is left with the painful impression that, like most other countries, Germany suffers from charlatanism. The author under the guise of science attempts to prove that almost all diseases that human flesh is heir to have their origin in disordered peripheral nerves; not the peripheral nerves that anatomists have taken pains to outline and describe, but nerve-points which only the author has discovered to be at fault. The inference is that he, the discoverer of this unknown territory, must become the guide. In a previous work he even gives a complete chart of these nerve-points, which strongly reminds one of Dr. Cook's map of the north pole which he has never seen. The author, like his compatriot, Dr. Friedmann, has been thoroughly discredited in his own country.

When to Send for the Doctor and What to Do Before the Doctor Comes. By Frieda E. Lippert, M.D., Assistant at the Psychological Clinic, University of Pennsylvania, and Arthur Holmes, Ph.D., Assistant Professor of Psychology, University of Pennsylvania. Cloth. Price, $1.25 net. Pp. 265, with 17 illustrations. Philadelphia: J. B. Lippincott Company, 1913.

This little book gives brief and pertinent directions for determining whether or not a child is ill; if it is ill what the probable trouble is and what is best to do until expert advice is available. The directions cover speech defects, minor deformities and mental backwardness. It ought to be very useful to the mother and the teacher.

Manual of Operative Surgery. By John Fairbairn Binnie, A.M., C.M., Surgeon to the General Hospital, Kansas City, Mo. Sixth Edition. Cloth. Price, $7 net. Pp. 1,251, with 1,438 Illustrations. Philadelphia: P. Blakiston's Son & Co., 1913.

This edition of Binnie's manual shows the continuous improvement which has characterized previous editions. Considerable space is given to the more rare and difficult operations, such as hypophysectomy, and to good discussions of the many operations familiar to all surgeons. Chapters devoted to operations on the stomach have been practically rewritten

Medicolegal

Construction of Statute Relative to Privileged Communications —What Adjudged Waivers—Application to Several Physicians

(Epstein vs. Pennsylvania Railroad Co. (Mo.), 156 S. W. R. 699)

The Supreme Court of Missouri reverses a judgment of the St. Louis Court of Appeals which affirmed a judgment for the plaintiff for personal injuries and held inadmissible the depositions of a Dr. Phelps and a Dr. Christie, both of whom were present while the plaintiff was being examined and treated and consulted with touching his injuries by a Dr. Elston, who was permitted to testify for the defendant without any question of statutory privilege being raised.

The Supreme Court, adopting the opinion of Faris, J., delivered in Division 2, says that no point was made touching whether or not Christie and Phelps fell under the facts within the category of those to whom the statutory privilege applied; it seemed to be tacitly conceded by the defendant that they were within the rule. Implied waiver arising from the facts was alone relied on. From the language of the statute, as well as from the trend of decision, the court deems it plain that these physicians were incompetent, unless from the facts implied waiver might be deduced.

The Missouri statute provides, that "the following persons shall be incompetent to testify . . . a physician or surgeon, concerning *any information* which he may have acquired from any patient while attending him in a professional character, which information was necessary to enable him to prescribe for such patient as a physician, or do any act for him as a surgeon." It will be noted that there is no provision touching waiver or any method of express waiver noted in this statute. Analyzing this clause, we see that all that is required is that the information be obtained by the physician while attending the patient in a professional capacity (thus excluding the necessity for the existence of an express, or even implied, contractual relation for hire, and including all cases in which from the nature of the services intended, or rendered, the relation of physician and patient arises). The information must be acquired while attending the patient in a professional capacity (thus excluding information obtained by a physician on a call on his patient in a non-professional capacity, for example, as on a social call or a call on other than professional business). And the information obtained in the capacity and under the circumstances above set forth must be such as is necessary to enable the physician to prescribe (thus excluding and rendering competent facts outside, and not cognate to, the patient's injuries and diseases).

The incompetency of a physician to testify rests solely in statutory enactment. It was unknown at common law, where the rule was that whatever silence might be enjoined on the physician outside of a court of law by the ethics of his profession, yet within a court of law he must unbosom himself of all facts within his knowledge touching the matter under inquiry, however obtained, present other requisites of admissibility.

Not all of the states, perhaps a bare majority only, have such a statute. It will not avail to say that the court is bound to a hard and fast construction of the statute—that it is to the court an *iron-bound law of the Medes and the Persians*, eternally unchangeable—and that the court cannot by construction engraft on it a single abatement, in jot or tittle, by invoking the doctrine of waiver, because, forsooth, there are no waivers or provisos therein expressly written. The court has, as has every civilized court where the statute exists, already engrafted by construction waivers on it, which are now so well settled as not to admit of question or quibble; for example, the patient may waive the privilege by calling his physician as a witness; the insured may waive the privilege, in any subsequent action, by contract in the policy of insurance. Other waivers, not so well settled, but well decided and resting on the soundest logic and reasoning, are (*a*) that if a physician to a patient-party in an action be called in the first trial by the adverse side and be allowed to testify without objection, then such act is a waiver of objection in any subsequent trial; (*b*) if the adverse side examine the physician of the plaintiff as to the fact of treatment, cross-examination by the patient's attorney as to the patient's condition operates as a waiver; (*c*) by failing to object to the question, the answer to which would involve disclosures of privileged communication between the physician and himself, the patient waives the privilege; and it has been said that it is too late to object, if the question has already been answered, that a motion to strike out the answer will not lie; and (*d*) by himself giving in evidence *voluntarily* the facts and nature of his ills and the communications had with and acts done by his physician in treating him, the patient waives his privilege to object.

It would seem, in reviewing the authorities, that much of this court's difficulty in harmonizing holdings has arisen from its efforts, and the efforts of other courts as well, to follow the holdings of the New York courts, which, however, touching the matter of waiver, are "cabin'd, cribb'd, confined," by their statute, which provides that the privilege granted to physicians of not testifying shall apply unless its provisions "are expressly waived on the trial or examination, by the person confessing, the patient or the client." This court concludes then, that indubitably the privilege of not testifying, as granted to a physician by the Missouri statute, is a privilege inuring alone to the patient, which the patient may waive, either expressly or by implication.

Was the testimony of Drs. Christie and Phelps, under the facts and the law, competent? If it was so competent, such competency, the court must concede, arose on waiver by the plaintiff in some wise occurring from what he said and did, or neglected to say or do; for the court thinks that these physicians, though not connected with the hospital, and inferentially only proffering aid in a great calamity for humane reasons, were yet in the shoes of those privileged by statute, absent waivers. Furthermore, the court thinks that these two physicians were competent witnesses, and that the court below erred in holding the contrary. Since the plaintiff had himself voluntarily gone on the stand, and, in his case in chief, as a witness for himself, laid bare for lucre's sake all of the secrets of his sick-room; since he had told and retold what Dr. Elston, his physician, said to him, and what he said to Dr. Elston; since he had told the precise nature of his alleged hurts as he said Dr. Elston found them, and since he had also voluntarily related the treatment professionally given to him by Dr. Elston, he waived the competency of other physicians, also there present, having knowledge of the identical facts.

Chief Justice Lamm, in a concurring opinion, says that, as he sees it, the rule announced does not come to destroy the statute, but to fulfill the statute in its very soul and sense; that is, its true intendment and meaning. It goes without saying that waiver should not be applied to every case mechanically and without reference to the facts, but with just discrimination and in view of the facts of each case. So used it is constantly applied in court as a most wholesome and useful device in reaching a just end.

While some of the language of the opinion is a little broad, yet such general language must be read with the concrete case held in judgment, and, so read, it does not mean that if a litigant uses a physician as a witness, thereby, and without more, every other physician he has ever had at other times, places or occasions may be thereby allowed to break the seal of professional secrecy. Nor does it mean that, a litigant saying or doing nothing of substance to lift the statutory veil of secrecy imposed on sick-room disclosures to his physician (arising by examination, conversation or consultation there), his physician may be allowed at the beck and call of the adverse party (and without leave or waiver by the patient party) to himself break the virgin seal of secrecy or lift its veil. If the privilege is personal to the party, and is thereby held in the hollow of his hand, why may it not be waived by act, conduct or word for the time, place or occasion in hand? If once waived, must the waiver not be held to operate to an extent limited only by logic and reason? The scandals in beating down the truth arising from a too harsh and literal interpretation of this law (if unaided and unrelieved by waiver) every one of us knows by experience and observation in the court-room. The application of such law must be with discrimination, so that it may have the legislative effect intended for it, and yet the investigataion of truth be not unnecessarily thwarted.

Society Proceedings

COMING MEETINGS

A. Assn. for St. and Prev. of Inf. Mort., Washington, D. C., Nov. 14-17.
American Physiological Society, Philadelphia, Dec. 27-29.
Clinical Congress of Surgeons of N. A., Chicago, Nov. 10-15.
Society of American Bacteriologists, New York, Dec. 31-Jan. 2.

Southern Surgical and Gynecological Assn., Atlanta, Dec. 16-18.
Western Surgical Association, St. Louis, Dec. 19-20.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION

Thirty-Ninth Annual Meeting, held at New Orleans, Oct. 23-25, 1913

The President, Dr. Albert E. Sterne, Indianapolis, in the Chair

Some Phases of Kidney Surgery

Dr. Henry J. Scherck, St. Louis: The objection to fixation of a movable kidney is that we fix rigidly an organ which normally has considerable motion. Further, we seldom remove the symptoms for which the operation is done, for in many patients the kidney condition is only one expression of a general enteroptosis, so that less benefit is derived from the operation than would have been the case had the patient been given a rest cure, fattening process and suitable binder.

I do not believe that operation should be done in every case of stone in the kidney. We should have at least some other indication and no pronounced contra-indications before performing a nephrotomy. In traumatism to the kidneys my practice is to wait, and be governed by the subsequent indications before operating. The majority of these patients recover without operation, provided infection does not take place. The operation can be delayed unless the patient shows symptoms due to continued loss of blood.

I have had occasion to operate in quite a number of hypernephromas. Unfortunately, in the majority of the cases the diagnosis was made rather late, and the records show recurrences and metastases in the majority of those operated on. Practically, however, a sufficient percentage of cases with operation show results which warrant us in operating as soon as we can make a diagnosis, either from symptoms or by exclusion. Persistent hematuria, either intermittent or constant, without evident explanation, has determined me in many cases and is my present indication for an exploration, as in the presence of such symptoms I suspect hypernephroma. I have noted in many cases the predilection of hypernephroma for bone metastases.

The Civic Importance of Some Phases of the Neuroses with Suggestions as to Their Control

Dr. Albert E. Sterne, Indianapolis: Of the many medical questions of civic importance probably none has ired reater prominence than that of drug addictions. morale, an health or precongenital defect in loss in earning they an economic civic problem of the highest order. to ations it touches many social conditions. Its the vice situation brings it startlingly into It is safe to assert that 80 per cent., prob- t., of commercial white slaves and their me rs of drugs. There is not a single community in this country or anywhere else in the civilized world which has not suffered from the effect of this great social disorder concealed though it be as far as possible. Various states have legislated or sought to legislate and legitimatize the traffic in habit-inducing drugs. Indiana last year passed a law regulating the sale and use of these drugs, but the law is too faulty to be of much use. It was drawn by druggists, wholesale and retail, and never was designed to wholly prohibit trade in these nefarious stuffs. In Ohio a somewhat similar law is being urged. In several other states an analogous situation prevails. This whole question is not one limited to any city, state or states, but is country-wide and can be solved only by the federal government. Restrictive legislation and control by states will help to some degree, but unless some laws are obtained and are enforced by all states, anything like adequate results would be mere speculation.

I would emphasize the national regulation of all habit-forming drugs of every type, but especially those of opium and cocain derivation. Concisely my plan is: 1. The establishment of a national warehouse or central depository for imported opium and cocain and like raw drugs. 2. The establishment of regional or district depositories either for a group of states or, if deemed advisable, for each state, either for raw material, or manufactured products, or both. 3. The appointment of authorized pharmaceutical agents to convert the crude products into commercial form. These three departments would constitute the business plan, the proper operation of which would enable almost perfect control of raw material and finished product.

Child Culture the Function of Organized Medicine

Dr. Henry B. Favill, Chicago: Any improvement in the conditions of future generations must be accompanied by an improvement in quality. The question is, How can the human stock be improved? The control of the unrestrained breeding of defectives is immediate and urgent. This, however, is only a small part of the problem. The real question is not how to prevent the bad, but how to develop the good. The difficulty is that our knowledge of heredity is not as yet sufficient to enable us to control conditions. The most that can be accomplished at present is the creation of a public sense of conscience and responsibility, at the same time making every effort to increase scientific knowledge regarding the factors involved in heredity and eugenics. This is a field in which physicians must be able to qualify as experts. As a whole, the medical profession has not hitherto risen to the situation. Legislation cannot proceed in advance of public opinion, and public opinion will not allow an invasion of private rights without overwhelmingly positive evidence being presented. This evidence must be secured and properly presented to the public by scientific physicians, if a public feeling of social responsibility is to be developed.

Child psychology and proper methods of pedagogy are also involved. Teachers cannot be expected to solve the problems involved without assistance from physicians. Parents are in need of assistance from both physicians and teachers. We must make ourselves competent advisers to the parent and the teacher in order to develop in each child the best of which it is capable.

Sanitary science can control mass conditions, but great progress in the physical welfare of the race will not be made until individuals are thoroughly trained in ideals as to health standards and their obligations to others. It is a deplorable fact that in medical schools in this country, instruction in personal hygiene is almost unknown, and instruction in psychology is unheard of. The only explanation of this defect is that the profession has not as yet realized its responsibility in these directions.

The Council on Health and Public Instruction of the American Medical Association, has undertaken to ascertain the exact public health situation in this country by inaugurating a survey of all public health agencies. This involves a survey of the public health work being done by the national government and a comparison of federal health work in this country with that of other civilized nations, as well as the development of practical plans for the establishment of a national Department of Health that will be second to none in importance in the government. Of still greater importance in this country is the state health work. Yet no one knows what is being done by the various state boards of health, because there is no standard or basis of camparison. The council has undertaken a detailed and painstaking study of this question. A trained sanitarian of the highest rank is about to make a personal study of every state board of health to discover the work, powers, equipment and support of the health department in different states. After this has been completed, a similar survey of the municipal health work is planned. Aside from official health activities, there are in this country many organizations springing from private initiative and supported by popular subscriptions. The importance of these organizations cannot be overestimated. Through a central committee, a similar survey of the work of these organizations will be carried on.

While the council is carrying on these investigations as to the existing health conditions, it has also started definite measures for the education of the public. A press bureau has been organized, which sends out to five thousand newspapers every week a press bulletin dealing with important public health subjects. The newspapers have recognized the fact that there is no sinister purpose or private interest behind this effort and they are using freely the material thus sent out. A speakers' bureau has been established, through which 130 of the leading physicians of the country are offered to local organizations for addresses on public health without expense to the local body. The speakers donate their time, the council pays their traveling expenses and the local organization furnishes the meeting place. A bureau of literature is also preparing and sending out pamphlets on public health questions, written for the instruction of the people. Many special committees are at work on special subjects.

A medicolegal bureau has been established to study public health laws in this country and others, and to draft, with the assistance of prominent educators, social workers, lawyers, judges, governors, and others, model laws for the protection of the public health. We recognize that in this work the legal point of view must be common.

Endocarditis with Special Reference to Its Etiology

Dr. Robert H. Babcock, Chicago: The tonsil is the most frequent atrium of infection in rheumatic fever and endocarditis of whatever type. I have made it a rule to investigate the condition of the tonsils in all cases of acute or chronic valvular diseases coming under my observation, and I invariably discover evidence or obtain a history of previous tonsillar infection. The main reason, perhaps, why the etiologic influence of follicular tonsillitis is not recognized more often is that the tonsillar involvement is very apt to precede the rheumatism by a number of days or even weeks. This is owing to the fact that time is required for the hemolytic streptococcus causing the tonsillitis to become converted into the rheumatic streptococcus. When this has been accomplished the latter strain is taken up by leukocytes and carried into the blood, and then is conveyed to the joints or to the capillaries of the valves where they set up the characteristic inflammation, and we see the phenomena of articular rheumatism and endocarditis, or in the case of a child only an endocarditis without joint involvement.

If the cardiac structures are not too extensively or malignantly affected the patient recovers in the course of time, but with a permanent valve lesion. In most cases the person suffers from recurrences of the rheumatism either acutely or in a mild subacute form, or every now and then he has an attack of tonsillitis of greater or less severity, usually the latter. Not infrequently the child has attacks of stomach trouble that puzzle the doctor as well as the parents. Such attacks are generally attributed to indiscretion in diet.

In many cases I have discovered slight, but to my mind convincing, evidence of appendiceal mischief and have attributed these stomach attacks to acute exacerbations of a chronic appendicitis. Generally, the family physician or the parent has been unwilling to accept the diagnosis and the case has been allowed to go on.

The *Streptococcus viridans* is a strain or modification of the pneumococcus. It does not itself occasion tonsillitis, but finds an unhealthy tonsil good soil for its growth. Consequently, it can be taken up by the leukocytes and carried into the blood-stream to lodge in the capillaries of the heart valves in the same manner as are the germs of rheumatism. If the capillaries are fairly abundant, as in the young, the bacteria may be attacked by the phagocytes and destroyed before they have time to grow and multiply. But if the capillary supply to the valves is poor, as is the case with sclerotic valves from former endocarditis, then leukocytes cannot get at and destroy the streptococci which, therefore, grow rapidly and produce massive vegetations.

Take care of the throats of children by the removal of adenoids and the correction of any other defect that predisposes to throat infections. Never regard any sore throat or tonsillitis in the young as trifling, and whenever a child displays languor, slight fever, etc., examine the throat. In any person with valvular disease who has recurring sore throat or rheumatic pains pay strict attention to the care of the throat, and if the tonsils are diseased, even though not enlarged, have them taken out, not merely clipped. Do not pass over recurring attacks of so-called indigestion with fever in a child with an endocardial lesion as merely a "stomach attack." Bear in mind the possibility of appendicitis in association with or as a result of rheumatic infection and tonsillitis, and direct particular attention to the appendix. A chronically infected appendix may serve as the atrium of infection.

The Functional Testing of the Cardiac Power

Dr. Charles Spencer Williamson, Chicago: In diseases of the cardiovascular apparatus, the examination of the quietly resting patient gives us no clew as to the functional efficiency of his heart, unless manifest signs of cardiac insufficiency are present. The most satisfactory method of arriving at a knowledge of the functional efficiency of the heart is by subjecting the patient to exercise tests. None of the methods which have been as yet devised are free from sources of error, and none furnishes a numerical estimate of the cardiac strength.

It is possible to obtain a very accurate estimate of the functional heart power by submitting the patient to an accurately measured exercise, such as climbing a certain number of steps, and by observation of the pulse, respiration and blood-pressure, together with the quickness of the return of these to the normal. The severity of these exercises should be strictly individualized, and in every case adjusted to the patient's general muscular development and conditions. For more scientific work, the only method which is capable of giving numerical results is that of obtaining the size of the heart before and after exercise, as determined by the orthodiagraphic method or some of its modifications.

Thrombosis and Embolism

Dr. W. L. Bierring, Des Moines, Iowa: In a series of seven cases of circulatory accidents, the acute infectious process in four instances was an acute tonsillitis, and one example of acute pleurisy and pneumonia, influenza (lymphadenitis), and appendicitis. As regards localization, the posterior tibial artery was involved in two cases, the middle cerebral three times, the axillary artery once, with one example of femoral thrombophlebitis and two of cerebral sinus thrombosis. In two cases multiple embolism occurred in the same patient. In summarizing our series of cases, which were all instances of acute infection accompanied by general bacteriemia or septicemia, tonsillitis, and apparently acute infection of the upper air passage, played a prominent rôle.

DISCUSSION ON DISEASES OF THE HEART

Dr. James Birney Guthrie, New Orleans: For a number of years I have been an exponent of the light percussion method of outlining the borders of the heart. The procedure of outlining the heart by percussion or roentgenoscopy before and after cough, timing the return to the original size of the outline, is a most valuable index of the integrity of the heart muscle. The healthy heart dilates on coughing to a degree perceptible during roentgenoscopy, but not appreciable by percussion. The time factor is quite as important as the measurement of the outward displacement of the right heart border. The graver the heart weakness, the longer the dilatation lasts. The longest cough dilatation time observed so far has been fifteen minutes and the shortest five seconds. This statement is based on careful examination of over one hundred cases. It is probable that this range of cough dilatation time will be extended on further observation.

Dr. Albert E. Sterne, Indianapolis: I wish to report a case of chorea, arthritis and endocarditis in a girl. A month or so before I saw her she had fallen down stairs and cut her forehead. The injury seemed trivial, but the wound did not heal, and in spite of every measure at the hands of an excellent surgeon the wound continued suppurating. In the course of the second week after the injury she developed polyarthritis. In the course of a few days, after the joint invasion, she developed a profound and severe form of chorea of the ordinary type. These cases usually develop severe infectious endocarditis, and in this case, in the course of a few days, the endocardial lesion occurred. Under careful treatment this child seemingly did very well, but she did not regain her strength; the joint condition practically disappeared, the chorea subsided, and the heart murmurs lessened, but did not entirely disappear. In about four weeks after the time the heart lesion first manifested itself the joints again became inflamed; the chorea again became severe; the heart sounds again became murky, and the child died of all the symptoms characteristic of thrombosis and embolism of the several sinuses.

Dr. F. M. Pottenger, Monrovia, Cal.: In advising the removal of tonsils I have sometimes wondered whether or not in removing them we were not taking away a source of protection to the patient. I have had the tonsils of my own children removed, but at the same time I feel that probably we are doing wrong in taking the attitude we do toward the tonsil as a whole.

Dr. Walter L. Bierring, Des Moines, Iowa: It is a matter of great interest to note that the relationship existing between focal infection, particularly of the biliary or intestinal tract, and its influence on the heart muscle and on the endocardium, is being corroborated by the work of Rosenow. Rosenow has established that acute infection of the tonsils, the endocardium and the appendix are all the same. He has gone still further and by modifying the organisms has produced experimentally cholecystitis with the same organism, and in another dog has produced typical round ulcer of the stomach.

Dr. Robert H. Babcock, Chicago: We are not justified in recommending the removal of healthy tonsils, whatever their exact function may be, but when a tonsil is no longer healthy, when it is diseased, I believe that the tonsil should be enucleated to safeguard the patient.

Differentiating Between Active, Quiescent and Healed Tuberculosis by the Character of the Reaction to the Cutaneous Tuberculin Test

Dr. F. M. Pottenger, Monrovia, Cal.: A positive clinical history, suspicious signs within the chest, and a maximum reaction to tuberculin within the first twenty-four hours give us grounds for making a diagnosis of active tuberculosis. With a questionable clinical history, questionable signs on physical examination, a reaction to tuberculin reaching its maximum after twenty-four, or particularly after thirty-six hours, I believe we are safe in saying that we are dealing with a partially quiescent lesion.

Results in the Treatment of Hip Disease

Dr. John Ridlon, Chicago: The mechanical treatment of hip disease aims to do for longer or shorter periods in most cases three things, namely, to immobilize the joint; to remove the weight of the patient from the joint in standing and walking, and to exert traction on the limb. A hip may be immobilized by a plaster-of-Paris spica as efficiently and as comfortably as in any way. The patient's weight can be removed from the joint by putting him in bed, this more efficiently than in any other way. Traction can be exerted by the use of weight and pulley, either with adhesive plasters applied to the limb after the manner of Buck or of Taylor. Some cases attain very good results without any treatment whatsoever; some attain very bad results under the most prolonged and best of treatments; but the orthopedic surgeon also knows that by treatment he lessens pain, shortens the duration of the disease, prevents a great deal of the deformity that would otherwise occur, and saves life.

The Feeding of the Sick Infant

Dr. Frank C. Neff, Kansas City, Mo.: One should regard constipation as an evidence usually of an intestinal indigestion. The constipated new-born baby fed entirely on the breast is with difficulty relieved through the diet. Correction of the mother's diet, digestion and mode of living may be tried, but often has little effect on the child. I have never attempted to administer fruit juices to infants less than 3 months old, but older infants will often tolerate from a teaspoonful to a tablespoonful of orange, grape, pineapple or prune juice with good results. Supplemental feedings of cow's milk with the addition of a malted gruel, such as the so-called malt soup, show a beneficial effect on the gray, dry, soapy stools. The effect of malt sugar is laxative, and of more benefit than any of the laxative drugs. Following a disturbance in balance which is not corrected, there is a decided intestinal disturbance with numerous watery, mucous stools, vomiting, and an elevated temperature. Fats, sugars and flour must here be reduced, and in severe cases also the whey contents of the food. Breast milk is preferable to any artificial feeding. Next comes Finkelstein's *Eiweissmilch*, and, finally, skim or buttermilk in case the other foods are not obtainable. These should be given in small quantities at first.

The feeding of infants suffering from the systemic poisoning resulting from improperly digested and assimilated food and also from infections must provide for elimination through the kidneys and stools.

The feeding of infants with pylorospasm has as yet shown little advance. Lapage advises regulating the feeding, using easily digested food that leaves no residue and has the greatest chance of passing the pylorus. He states that it is advisable to give small amounts, even as little as a teaspoonful, frequently until the child improves and vomiting ceases. Sometimes a change of food alone will lead to temporary improvement. Feeding through a tube without much dilution of the food is advisable, after washing the stomach. Nutritive enemas are of doubtful value.

Pyloric Stenosis in Infancy; an Analysis of Twenty Cases

Dr. H. M. Richter, Chicago: Of the twenty cases, eighteen were of the type described as hypertrophic pyloric stenosis; two were of the type known as spasmodic. In all of the eighteen a definite, firm, olive-shaped tumor was demonstrated at operation; in seventeen of the eighteen it was palpated and recognized through the abdominal wall before the operation. In the one case in which it was not palpable before operation, the clinical findings were so clear that the diagnosis was made without reserve. The tumor consisted of a firm, olive-shaped body, roughly from ½ to ¾ inch in length. It was covered by smooth, glistening peritoneum that had the appearance of being stretched over the mass. There was no external evidence of inflammatory reaction; no attempt at fixation. The mass was freely movable, and this mobility was recognized clinically and is, in fact, probably the cause of the frequency with which clinicians have failed to demonstrate it. The tumor had the firmness of cartilage; it was not soft or pliable in any case; there was no case in which its consistency made the finding questionable; no case in which a gradation could be made out between the tumor mass and the adjacent stomach and duodenum; it was sharply defined. In two cases in which a pyloroplasty was done, and in one case that came to necropsy, a section of the pylorus showed the mucosa to be relatively redundant, so that it bulged out of the incision when relieved of the compression by the tumor. The histologic picture was that of a simple hyperplasia of the circular muscle fibers, with no change in any other structure of the pylorus.

The stomach, when it had not been emptied before opening the abdomen, was always found distended to a marked degree of tension; the duodenum was always empty and collapsed. It was perfectly evident that the tumor formed a complete obstruction of the canal. In none of the eighteen cases was there any congenital malformation, though in one a particularly short mesocolon made it impossible to do a retrocolic gastrojejunostomy.

I wish to emphasize, first, that the mortality has been reduced below that claimed by any method of non-surgical treatment, and second, and of equal importance, that the ultimate condition of the patient is that of a normal individual.

Some Points in the Treatment of Acute Ileocolitis

Dr. J. Ross Snyder, Birmingham, Ala.: The first thing I insist on is that to be rational the treatment must be individual. There are, however, certain principles of treatment applicable to all cases. With the onset of the disease, it is imperative that the intestinal tract be cleaned out. My personal preferences for this purpose are castor oil by mouth and normal saline solution for irrigation of the bowels. If there is troublesome or persistent vomiting, the stomach should be washed; the washing to be followed by the administration of broken doses of calomel until ½ to 1 grain is given; and still later followed by castor oil. Although the initial purgation and irrigation are essential, I wish to protest against the practice of giving a daily dose of oil and of continuing frequent irrigations. This is not only useless but absolutely contra-indicated in that it destroys all possibility of rest to the inflamed and ulcerated bowel. If toxemia of grave nature accompanies the onset, a hypodermoclysis of salt solution should be given without delay. Given early in the attack, salt solution is often an excellent and sometimes necessary measure, but I am convinced that after the heart has been weakened by the ravages of this disease, the subcutaneous injection of salt solution is not only futile but it is capable of producing disastrous results by overcrowding the heart.

By stopping all food, by clearing out the intestinal tract and, if necessary, by the use of salt solution subcutaneously, the toxemia in the majority of colitis cases promptly subsides and the disease becomes a purely local one, demanding for restoration to normal nothing so much as rest.

If peristalsis continues irritable and excited, it is my practice to use opium more and more freely. Without its use in acute colitis, the disease is often unnecessarily prolonged and its dangers are frequently augmented. Children suffering from colitis bear opiates a great deal better than they do the wear and tear and the strain accompanying the irritable peristalsis. Once the intestinal tract has been relieved of toxic decomposing, and irritating food residue, opiates should be called into quick service and they should be given in amounts sufficient for the purpose intended. Rest is not only to be assured by withholding further purgation, by withholding food, and by the use of opiates, but the environments of the child should be made peaceful and quiet. The child should be kept in bed in the recumbent position.

AMERICAN ROENTGEN RAY SOCIETY

Fourteenth annual meeting, held in Boston, Oct. 1-4, 1913

(Concluded from page 1745)

Roentgen Therapy of Enlarged Thymus

Dr. Sidney Lange, Cincinnati: Desiring to prove the action of the Roentgen ray on the thymus I roentgenized a series of young rabbits. The result was a slight shrinking to complete fibrosis of the gland. It was possible to produce any desired degree of fibrosis by varying the intensity of the treatment, and the intervals between treatments. Clinically, the treatment of enlarged thymus with the Roentgen ray has produced equally good results. Roentgen therapy is the method of choice in cases of enlarged thymus in children, whether the symptoms be mild or urgent. In five cases treated by me splendid results were obtained. Children whose physical or mental development is retarded should be roentgenoscoped with a view toward determining whether the thymus is enlarged. Roentgen therapy as a precautionary measure or as a preoperative treatment may enable children of the so-called lymphatic type to withstand intercurrent disease, and anesthetics, which might otherwise prove fatal. I believe that the routine preoperative roentgenization should be resorted to in cases of hyperthyroidism, with a view to lessening the operative mortality. No untoward effects have thus far been noted.

Roentgenography of the Ileocecal Valve and Appendix

Dr. James T. Case, Battle Creek, Mich.: In doubtful cases of appendicitis an injection of the colon with bismuth under the guidance of the fluoroscope followed by careful and intelligent palpation of the abdomen may be of service. When the lumen of the appendix is closed, bismuth will fail to enter, but in the large percentage of cases in which the appendix shadow can be studied under the fluorescent screen there are a number of facts capable of demonstration, such as the position of the appendix, its outline, whether it is kinked or obstructed, and even the presence of a pericolitic membrane. I have secured roentgenograms of bismuth in the appendix in over three hundred cases. In one series of 827 examinations the appendix had been removed in 64. Out of the remaining 763 cases the appendix was demonstrated in 273. I do not believe that the ratio of patent appendices can be very much greater than one in three of patients with gastro-intestinal symptoms. I do not assert that every appendix which permits the entry of bismuth is in need of surgical attention. There are many cases in which surgery is distinctly not indicated, for instance, when the contents of the appendix have disappeared by the time the colon is emptied. I examined five patients who were being given bismuth in 15-grain doses in the course of treatment of acute gastric disease. In all five bismuth was found in the appendix, in one of them on the nineteenth day after the last dose of bismuth. In my series of 273 cases in which the appendix was filled with bismuth there was definite tenderness over the appendix in 236 patients. The appendix has been removed in eighty-eight of these, and in all but a few pathologic reports showed disease of the appendix.

DISCUSSION

Dr. W. B. Cannon, Boston: It has been shown conclusively that in cats and dogs there is a thickening of the circular muscles at the terminus of the ileum, a sphincter analogous to the pylorus and cardiac sphincter. Whether there is such a sphincter in man has not been settled. If there is actually a sphincter between the large and small intestines, it is quite conceivable that that sphincter is managed by conditions in the canal itself. The acidity of the stomach content holds the gastric sphincter closed. The acidity in the duodenum closes the pyloric sphincter. It is possible that the state of the food as it comes from the small intestine into the large serves to keep the valve closed. I have never seen food coming from the small intestine into the large forced back by antiperistaltic waves into the small intestine. On the other hand, the introduction of a large enema of starch paste and bismuth quite frequently is pressed back into the small intestine, which may mean that the ileocecal valve is incompetent. It may be competent for material which comes through it normally, but incompetent for material produced in an abnormal manner.

Dr. A. Howard Pirie, Montreal: I had a case in which the bismuth was seen in the appendix six hours after injection, and until twenty-two days afterward. On the forty-third day the patient was operated on for appendicitis. I do

39. **Postoperative Intestinal Stasis and Intra-Abdominal Use of Oil.**—Burrows has carried out a series of animal experiments showing the harmlessness and value of neutral mineral oil, used intra-abdominally. He states that in most simple abdominal operations its use is not required since prophylactic care will limit postoperative distress, but in all others the oil is of the greatest value when employed on abdominal pads during operation or sponged gently on intestinal coils previous to closure of the incision, excluding only areas where adhesions are desired and having care that all plastic procedures and intestinal anastomoses are completed before oil is introduced. In cases presenting extensive adhesions or wide-spread peritonitis, large amounts of oil (up to 6 or 8 ounces) are required to prevent recurrence or formation of adhesions, to limit the absorption of toxins from the peritoneal cavity, to assist nature in combating infection, and as a prophylaxis against intestinal stagnation, obstruction, spasm, and final paresis. In the case of more than moderate severity, intestinal spasm and stasis, together with abdominal pain, are largely eliminated and convalescence is more comfortable and safe, while the individual in dire straits at the time of surgical intervention has, postoperatively, manifoldly better chances of recovery.

His conclusions, based on the peritoneal reaction to chemical irritation and on the results of using neutral oil intra-abdominally to control infection and effects of traumatism, both mechanical and chemical, as observed in guinea-pigs and dogs, are as follows:

1. Iodin, mercuric chlorid solution, carbolic acid, alcohol, etc., applied to the peritoneum, rapidly spread beyond the area intended, through capillary action and affinity for the tissues, destroy the endothelial cells, cause an excessive exudate and tend to produce permanent adhesions.

2. Olive oil, containing fatty acids, and commercial liquid petrolatum, the impurities in which are acids,, rosins, fats and oils, both animal and vegetable, [illegible] ubstances with a bland oil, produce inflammat[illegible] surfaces, as is shown by the occurrence of a watery hemorrhagic exudate, which differs, however, from that which takes place in the absence of oil, in that agglutination and organization do not follow.

3. Bland, non-irritating oil, represented by a purified liquid petrolatum causes none of the changes occurring in the process of adhesion formation, which are endothelial cell injury, coagulable exudate, agglutination, organization, and finally connective tissue and fibrous scar formation. The oil has no appreciable chemical action on the tissues nor deleterious effect on the animal and is slowly absorbed.

4. Oil, used intra-abdominally in sufficient quantity, prevents, to a great extent, the formation or recurrence of adhesions.

5. Oil fills the lymphatic channels leading from spaces denuded of peritoneum or opened by incision, thus limiting septic absorption, and, through preserving the endothelial cells, prevents extension of destructive processes.

6. Oil is used to advantage, intra-abdominally, in place of salt solution, on abdominal pads, and to protect and lubricate the abdominal contents, thereby eliminating or minimizing postoperative intestinal statsis, vomiting and abdominal pain.

42. **Uric Acid in Blood-Serum.**—The technic of Roethlisberger's method is as follows: A small quantity of blood is drawn from the finger-tip or the lobe of the ear into a special glass tube, from 10 to 15 drops being usually sufficient for from six to nine tests, which are made simultaneously and serve to control one another. The glass tube must be kept in an upright position for several hours, until complete separation of the serum has taken place. If necessary—especially if placed in an even temperature—the blood may be kept from twelve to twenty-four hours. If kept for a longer period of time there will be loss of uric acid by fermentation or putrefaction.

The best environment for the test is a dark room with a red light, though equally good results may be obtained in a room with a subdued light, or one lighted by a small electric bulb placed at a distance of two or three yards. Two, three, or more strips of the reagent paper—a special kind of filtering paper impregnated with nitrate of silver—are placed on a glass slide. The silver paper should not be exposed to the light except during the time necessary for manipulations; in the intervals it must be screened. With a dropper, 15 per cent. solution of carbonate of soda is dropped onto the paper, allowing a certain margin to surround each drop. The drops must be very small and must absorb quickly, leaving a perceptible round spot. After waiting two or three minutes, a quantity of the blood-serum is withdrawn by a dropper from the glass tube containing the blood; it is dropped slowly on to the round spots made by the carbonate on the test papers. In two or three minutes more the strips of paper are lifted from the glass slide and placed to soak in a porcelain or earthenware dish filled with water The nitrate of silver now dissolves, while the carbonate remains insoluble. The basin must be kept covered to protect the strips of paper from the light until the nitrate is totally dissolved, which generally requires at least thirty minutes. They may be left to soak much longer without harm. The strips are now ready for fixation. They should be removed from the basin and placed in a solution of ammonia (one part of pure ammonia to four parts of water), which removes any unreduced carbonate of silver. Five minutes are sufficient for this process. The strips of paper are then placed in clean water screened from the light, to wash them thoroughly and to remove the ammonia and remains of the salts of silver. After remaining for several hours in the water, the strips are dried between blotting or writing paper, care being taken to protect them from the light. The dried strips are then ready to be placed under the scale; a color scale is necessary for the determination. By comparing the color and the intensity, the degrees of reaction and the proportion of uric acid contained in the blood can be determined. Only spots with distinct outlines are to be considered.

49. **Blood Studies in Constipation.**—Hoxie claims that intestinal stasis affects the blood-picture, producing a picture characterized by changed color reaction and an increase in the number of immature cell forms. One hundred cases reported on by him fall into three general groups: (1) those in which the lesion is in the upper bowel or stomach; (2) those showing colonic stasis, and (3) those in which the stasis has produced systemic effects. The tendency is toward a high total count. The percentage of the mononuclears is increased. Quite generally the granular cells stain heavily with the blue. The second group is characterized by a total count toward the upper limit of the normal. The color reaction differs quite distinctly from that of group one, for the granular cells are stained both by the red and the blue, thus giving a dirty mauve nuance. As soon as the stasis produces an irritation of the hematopoietic organs ("auto-intoxication"), the leukocyte count goes above the 10,000 mark and the number of immature forms rapidly increases (Arneth's "shift to the left"). It would seem as if the lymphadenoid tissue were inhibited so that the fully developed small lymphocytes were not being produced in sufficient numbers, nor in as relatively great numbers as the ripe granular cells.

56. **Special Technic in Palpation.**—The correct employment of palpation for the recognition of disease of the lung is believed by Boston to be among the most valuable of physical methods. Whenever it is desirous that the exact extension of a pulmonary lesion be ascertained, palpation serves this purpose equally well, and at times more advantageously than any other physical method. A useful practice is to employ only the index fingers of the two hands. The tip of the index finger receives sensations from an area of the chest approximately the size of a dime. But little additional time is necessary to traverse the entire chest-wall in this manner, and the results obtained are by far more valuable than those gained through the application of two or more fingers of the same hand to the surface of the chest. The index finger is decidedly more sensitive than are the other fingers.

After it has been found that a certain portion of the chest gives increased fremitus, the next step in the examination is to determine the exact extension of the lesion accountable for such fremitus. This Boston does by placing one index finger some distance beyond the area where increased fremitus is produced, and traveling slowly with this finger toward the lesion. Whenever the palpating finger reaches a point where the fremitus is increased, this point should be designated by the pen. This same procedure should be employed to ascertain the boundary of the area of abnormal fremitus on all sides. After the area of increased fremitus has thus been roughly outlined, place one index finger immediately inside the limiting line, and on the area where fremitus is increased, and at the same time place the index finger of the other hand but a short distance beyond the line. In this last position carry the two fingers in a steplike manner along the line designating the approximate limitation of the area of increased fremitus. The finger palpating over the lesion will be found to elicit increased vocal tactile fremitus, while the other index finger palpating immediately beyond the lesion detects a lesser degree and in many instances normal fremitus.

In palpating for the detection of expansible pulsation, the position of the operator's fingers must vary, depending on the location of the aneurysm. Apply the four fingers and the thumb to the pulsating mass in such a way that they more or less completely surround it. The sensation of true expansion with each heart-beat is conveyed to the operator's hand most distinctly. This method has been employed by Boston in distinguishing between aneurysm of the carotid regions and pulsations due to other causes. In studying aneurysm of the abdominal aorta and pulsations conveyed through some solid viscus or growth, this technic has proved of inestimable value.

In palpating for the edge of the liver, a procedure of real worth, Boston claims, the method is as follows: While the patient is standing place the fingers of the palpating hand at approximately the lower border of the liver; and direct the patient to raise the heel of the right foot so that he stands with but a small portion of his weight on the right toe. This position will be found to relax the abdominal wall over the right hemisphere. This method serves of equal value in palpation of the right kidney, and of the appendicular and pelvic regions. The same procedure is equally well adapted for the study of the left abdominal hemisphere.

57. **Induced Pneumothorax.**—Schwatt uses oxygen gas for the first, and frequently for the second injection. Under no circumstances is any gas allowed to flow in before there is a conclusive indication that the point of the needle is in a free pleural space. A distinctly negative reading with both inspiration and expiration, and a greater negative reading with inspiration than with expiration, are practically conclusive evidence that the needle has entered the pleural cavity. As a further indication the patient is instructed to take a moderately deep inspiration and to hold his breath at the end of it. If the manometer then remains stationary at a negative reading, one may be certain that the point of the needle has reached a free pleural space. Should the point of the needle be in the lung tissue, the column will drop from negative to zero while the patient is holding his breath. The insertion of the needle into the lung tissue is in itself devoid of any danger. It is Schwatt's practice to inject the gas in small quantities especially at the first operation. No more than from 50 to 100 c.c. of gas are injected without taking a manometer reading. It is Schwatt's opinion that many unfavorable results, both immediate and remote, are produced by injecting large amounts of gas. Except in cases in which it is sought to induce a pneumothorax for the purpose of stopping hemorrhage, nothing can be gained, and great damage may be done by injecting large amounts of gas. It is equally wrong to inject the gas under a pressure greater than that furnished by the injection bottles.

86. Abstracted in The Journal, Dec. 7, p. 2090.

87. **Epitheliolysis Against Carcinoma.**—The cells of carcinoma have a strong tendency to degenerate soon after formation. They are, therefore. on a plane of less resistance than those of the normal type of epithelia, whether merely investing or more specialized; could this natural tendency to degeneration be hastened and intensified without injury to normal epithelia, or would it be necessary to make the lytic power strong enough to affect them also in order to entirely destroy the neoplastic cells, and how would this be recognized and controlled clinically? These are Thayer's premises. He found that repeated intraperitoneal injections of washed sterile epithelia, injected at five-day intervals, caused general destruction of practically all the epithelia of the recipient animal The organs, sectioned in paraffin, showed degenerative changes in proportion to the frequency and amount of epithelia injected, and clinically the animals developed diarrhea and other symptoms corresponding to such lesions. So many experiments of this kind were performed and the result was so constant that the first part of the working hypothesis was regarded as established.

The next step was to try a similar procedure in a case of inoperable carcinoma. For this purpose several autolysates of epithelia were prepared, the washed material sterilized over chloroform and kept in the incubator at 37 C. for a couple of months, then filtered and tested for the presence of germs and ferments. When ready for use it has the following characters: It is of light straw color, of a specific gravity of 1.008-1.010, faintly alkaline; either dissolves out a trace of fat but causes no precipitate; nitric, picric and trichloroacetic acids give a fine precipitate [illegible] do [illegible]ontains no bile, no proteolytic ferments (others not tested) represen[illegible]does contain 1/10 per cent. of urea and 0.19 per liter uric acid; before use it is tested by both aerobic and anerobic cultures and found to be sterile.

The clinical experiment was performed in a case of inoperable carcinoma of the cervix. July 25, 2 c.c. of the filtered lysate, diluted with 10 c.c. sterile physiologic salt solution, were injected under the skin of the right side, between the ribs and the iliac crest. By the 28th, pain was a little less; this symptom had been continuous and unrelieved by the operation. On this date 5 c.c., well diluted as before, were injected. Since she had had no reaction beyond a half a degree of temperature, it was thought safe to double the dose, the point of injection being the left flank. August 5, 10 c.c. were given, August 8, 10 c.c., and August 16, 12 c.c. The site of injection has at no time shown any redness, induration or tenderness. At the latter date the patient's cachexia had practically disappeared, her vaginal discharge had nearly ceased and had lost the foul odor entirely, the lymph-nodes of the groins were barely palpable, the pain in the abdomen had ceased and but little was left in the right thigh, and in the week of August 2 to 8 she had gained 2½ pounds. The patient's condition, August 20, is still satisfactory.

106. **Congenital Atresia of Esophagus.**—Richter's plan of operation consists of closure of gullet at tracheal junction by transthoracic route and gastrostomy.

107. **Fibroma Molluscum Gravidarum.**—Brickner adds an observation, which, as far as an exhaustive study of the literature is concerned, is unique. The condition is a longitudinal pigmentation of the nail of the index finger of the right hand and of the middle finger of the left hand. The patient was a primigravida. During the later months of her pregnancy she noticed this discoloration of the nails. It was at first of a light brown but became deeper in color as the pregnancy advanced. There was no unusual pigmentation of any of the rest of the body, the linea alba and the areolae being no more deeply pigmented than usual. Her child is now 15 months of age. The color has gradually disappeared from the nails, but the pigment is still present. It is three-sixteenths of an inch in width and is at present of a light yellowish brown color.

112. Tuberculin in Surgical Tuberculosis.—In Swenson's experience, tuberculous gland infections that have not entered the stage of caseous degeneration have yielded to tuberculin treatment. He says that almost all local tuberculosis may be cured under persistent, skilful, surgical treatment, assisted by tuberculin injections properly given. Tuberculin injections may be safely given every tenth or twelfth day without opsonic work; of course, it is preferred that one be guided by occasional blood-tests. All tuberculin injections should be given by a reliable, clean person, and the best place for the injections is on the anterior part of the chest. Duration of tuberculin treatment; one half to two years. All hygienic treatment, such as fresh air, good food, and attention to digestive organs, is of vital importance. For tuberculous sinuses extending into the urinary bladder the bismuth paste injections are usually contra-indicated.

114. Simple Method of Excluding Pylorus.—A metal spatula is introduced through a slit in the gastrocolic ligament to protect the structures behind the stomach, then a metal skewer is thrust directly through both walls of the stomach into the lesser peritoneal cavity and out again so as to encompass about one-half the distance between the two curvatures. A clamp is placed behind the skewer and several mattress sutures introduced between the skewer and clamp; these embrace the whole thickness of both walls of the stomach. The skewer is cut out with a sharp knife and the mattress sutures tied before the clamp is removed. A hemostatic running stitch of silk or linen unites the four exposed cut edges (it may be inserted before the clamp is removed). The ridge of tissue formed by the mattress sutures is inverted with a continuous Lembert row. None of the ten dogs on which Bartlett used this method died from the effects of the operation. The excluded portion was pale and strikingly atrophic at autopsy in each case, while roentgenoscopy showed the obstruction to be complete and the gastro-enterostomy patent in the three which were examined months after operation.

122. Modern Extraperitoneal Cesarean Section. — Hirst's experience with extraperitoneal cesarean section comprises nine operations in the last eleven months without maternal or fetal mortality. Two of the patients were presumably infected beforehand and one had placenta praevia. The first three operations were done by Frank and Bumm's technic; the next three by Sellheim's; the last three by Veit and Fromme technic with a slight original modification which Hirst believes decidedly improves the operation. It consists in suturing the peritoneal flaps before opening the uterus. The lower abdomen is incised down to the symphysis pubis; the perietal peritoneum is opened in the usual manner; the lower visceral peritoneum on the lower uterine segment is opened in the same way. The two peritoneal flaps are sewed together on each side, thus closing the peritoneal cavity; the lower uterine segment is incised from above downward, as low as necessary to deliver the child, the bladder being protected by a retractor over the symphysis; a forceps is applied to the child's head; the placenta and membranes are removed; the uterine wound is united by a two-tier catgut stitch; the double peritoneal flaps are brought together in the middle line over the uterine wound by two or three interrupted stitches, and the abdominal wound is closed in the usual way.

125. Obstruction of the Intestine.—One case cited by Collins was due to strangulation caused by a fibrous band across a hernial sac; the other from intussusception caused by a lipoma of the cecum.

3. Rigidity of Calcified Arteries.—It is held by MacCordick that during life the calcareous matter in the arterial wall is not present in the form of rigid plates. It is there, but in the state that may be compared with unset mortar. It is generally accepted by chemists that the process of setting of mortar is one of conversion of calcium hydroxid into calcium carbonate by the absorption of carbon dioxid from the air. Kept under an alkaline solution, or kept in bulk away from the air that contains carbon dioxid, mortar remains unset. A mixture of calcium carbonate and calcium phosphate remains soft so long as it is in an alkaline medium; placed in an acid solution it sets. Also the more strongly acid the medium the faster it sets. The reaction of the tissues and body fluids during life is alkaline, but becomes acid shortly after death. It is deserving of note particularly, in the second place, in connection with arterial calcification, that the gas which after death replaces the blood within the arteries is largely composed of carbon dioxid. Without doubt when there are large areas of necrosis appearing in the tissues, there the production of acid is the cause of the setting of calcareous matter. For instance, it is the experience of the gynecologist that a calcified fibroid of the uterus may be found of stony hardness even while in the body; so also MacCordick's experience is that in a case of senile gangrene the arteries of the necrosed or gangrenous area are of stony hardness, whereas the same arteries higher in their course, where the circulation is still maintained, are soft and pliable and can be ligatured with ease. In short, he says, in arteries provided with an adequate circulation the calcareous matter, whether it be in the intima or the media, remains unset. It is easy, then, to understand why, after handling pipe-stem radials, there is no thrombosis and gangrene, easy to understand why rigid and tortuous splenic and other mesenteric arteries in the aged arteriosclerotic do not undergo traumatic rupture. During life they are not rigid. It is easy also to understand the occurrence of extensive so-called atheromatous ulceration of the aorta without thrombosis, commonly occurring during life. Those ulcers, in short, and the saucer-like plaques with surrounding rupture of the endothelium are postmortem productions. The calcified areas become in the intima set and rigid before the muscular contraction of the aorta gives way and the tube undergoes dilatation. The result is that a tension on the endothelium at the edges of the plaque induces rupture of this lining.

14. **Circulatory Disorders and Alopecia Areata.**—Thirty-six cases were examined by Walsh. Of these 23 were in males and 13 in females; 14 were under 20 years of age, and 6 were 50 or over. Of the 36 patients no less than 24 had valvular murmurs and other evidence of cardiac disease, while 3 others showed general arteriosclerosis (one advanced atheroma). Of the remaining 7, one had exophthalmic goiter; one chorea and irregular heart action; one irregular action from tea and another from tobacco poisoning; one had a feeble circulation; while in three only could no marked abnormal circulatory condition be detected. Of the 24 valvular conditions, 18 showed mitral regurgitation, and 2 of them aortic mischief as well; 5 were direct aortic, 2 of them direct and regurgitant; and one showed multiple murmurs in a terminal stage of cardiac disease. Walsh says that it may be objected that in cases of alopecia following mental shock the cause is evidently neurotrophic, and that cardiovascular disturbance does not enter into the question. The answer is that shock does not produce alopecia areata in all individuals but only in those who have a certain predisposition, which may be either cardiovascular, or due to a temperament in which the heart is peculiarly liable to be disturbed. Some years ago Walsh described a type of individuals characterized by a congenital high forehead and abnormal thyroid gland, in whom shock was apt to be followed by a curious symptom-complex in which were to be found tremors, nervousness, depression, tachycardia, palpitation, headaches, exophthalmos, diffuse and patchy baldness, and so on. There was a special tendency to exophthalmic goiter and myxedema, the two being sometimes associated. This temperament, with its consequences, was often met with among poorly-fed children in an outpatient department. So far as myxedema is concerned, Walsh cannot recall a single case in which the patient had not a congenital high forehead. Where shock is followed by alopecia areata the same condition, in his experience, is almost always present. The associated instability of the heart condition in such cases is shown by the quick and variable pulse, the palpitation, and sometimes by the physical signs of a dilated heart. Walsh's main conclusions are as follows: The abnormal loss of hair, whether acute or chronic, diffuse or patchy, is in the majority of cases associated with some serious cardiovascular defect, which constitutes an essential predisposing cause. Given this predisposing cause the exciting cause may be one of various agencies, acting either directly or indirectly. Alopecia areata is simply a localized form of diffuse baldness, and both are probably due in most cases to exciting traumatism and predisposing cardiovascular defect. The predisposing cardiovascular condition may be (a) cardiac valvular. myocardial, or functional; (b) vascular, as arteriosclerosis; (c) neurovascular, as exophthalmic goiter or Raynaud's disease. In some cases the skin sign, in the form of alopecia or eruption, may register a failure of compensation. For instance, when an attack of influenza breaks down the compensation of a preexisting valvular lesion, an acute shedding of hair follows. From a pathologic point of view the predisposing part played in these cardiovascular cases depends on a disturbed balance of the surface circulation and acts in a twofold manner: (1) by diminishing the natural local defenses of the skin circulation against the invasion of bacteria from without; (2) by predisposing to the formation of clots, with subsequent damage to nutrition and shrinkage of capillaries (fibrosis); (3) by inducing lymph stasis.

36. **Relief of Pain of Laryngeal Tuberculosis.**—In twelve selected cases of laryngeal tuberculosis, Davis injected a solution of 2 grains of eucain in 1 ounce of 80 per cent. alcohol to relieve the dysphagia. The method of injection adopted is briefly as follows: The patient is in the prone position with the head and neck slightly extended and the chin turned away from the point of injection. To avoid sepsis the skin in the region of the nerve is painted with iodin. The larynx is pressed out of the midline by the thumb and made to project on the side about to be injected. The nerve is marked out by the nail of the index finger, which is placed between the hyoid bone and the thyroid cartilage and immediately above the superior thyroid tubercle where a tender spot is found. The blunt needle of Schlosser's syringe is now pushed in with a jerk at right angles to the surface and at the middle of the finger-nail to a depth of 1½ cm., i. e., to the mark on the needle. The needle is carefully moved so as to seek the spot at which the patient complains of pain in the ear. A few drops of the solution of alcohol are injected, and if there is a violent fit of coughing it indicates that the needle has possibly entered the pharynx and is too deep, but this very rarely happens. Finally, the slightly warmed alcoholic solution is injected until the pain in the ear has ceased. About 1 to 2 c.c. is generally sufficient. Of the twelve cases mentioned not one showed any signs of hemorrhage, injury to the surrounding structures, or other disturbing results—in fact, the proceeding is not much more difficult than the usual hypodermic injection. With the laryngoscope the side of the larynx injected was found to be slightly paler, and appeared to be less sensitive when touched with a laryngeal probe. This local anesthesia is probably the cause of the immediate

relief experienced in most cases. In two cases both nerves were injected at the same sitting without any untoward symptoms and without the regurgitation of fluid into the larynx during swallowing, but as a general rule, it is wiser to allow a few days to elapse before the injection of the second nerve. Of the twelve cases two were unsuccessful, owing to ulceration of the pharynx in one and extensive disease in the other. One patient obtained complete freedom of pain for one month and put on 3½ pounds in weight in a week. This patient died a few months later from diffuse pulmonary tuberculosis, and microscopic sections were made of the internal laryngeal nerves and compared with a section of the same nerves of a healthy subject who had been killed by an accident. The nerve which had been injected twice showed increased fibrous tissue and numerous spaces within the bundles of the nerve fibers.

37. **Hereditary Optic Neuritis.**—The eleven cases cited by Worton occurred in one family in three generations. All the patients were males. The age incidence varied from 9 to 32 years. Of the four cases personally examined two had regained practically normal vision but leaving some deficiency in the light sense, especially in one case; one patient is still under observation; and in one vision is reduced to hand movements close to the eyes. Of the remaining six living patients nothing is known of the present visual condition of two, one is stated to be blind, and the sight of one bad, while improvement has occurred in two cases. It is noteworthy that in all the cases in which visual power was completely regained or had partially recovered, the age incidence of the disease was below 20 years. Worton suggests that this would seem to have a bearing on prognosis.

40. **Treatment of Ankylostomiasis.**—A point of great importance in the successful treatment of ankylostomiasis in Keith's opinion, is the percentage of hemoglobin in the blood. If the percentage of hemoglobin is in the neighborhood of 60, he says it may be reckoned that with suitable treatment the ova will disappear in the course of a few days. With a percentage of between 45 and 55, treatment will be more difficult. Anything below 40 per cent. will indicate that great patience will have to be exercised before recovery can take place; it will not be a question of weeks but of months, and this is certainly so when the percentage of hemoglobin is as low as 10 to 20. The general condition improves with rest and diet. As a rule, the edema soon disappears and the patient feels better, but the ova, though they decrease in number rather quickly at first and then more gradually, do not disappear entirely for months, while the hemoglobin index remains persistently about its original level. From recent results Keith has come to the conclusion that betanaphthol in 30-grain doses, the first thing every morning, is likely to prove more effectual than eucalyptus or thymol. The necessity for starving patients while the treatment is being carried out is by no means evident; indeed, in bad cases it may even be harmful. More especially is it unnecessary if the drug is given the first thing in the morning. There will not be much food found in the upper part of the small intestine five or six hours after an ordinary meal, so that if the drug be given the first thing in the morning there is no necessity for starvation. Energetic treatment is needed, and Keith has never seen any ill-effects follow from such measures.

43. **Pathogenesis of Cancer.**—The parasitic theory of cancer, De Keating-Hart says, is given up, not as being impossible, but because, according to the present state of knowledge, it is unlikely and irrational; in microbial diseases, the injured cell leaves the virus intact, and one would, therefore, have to imagine a parasitism contrary to the histologic laws of higher organisms. The absolute similarity is recognized of the conditions which govern the grafting of normal and cancerous cells, and determine failure or success. It has been shown that ectopy, and the metastatic capability of cancerous cells are the consequences of their acquired properties, and of their cellular construction. The irritative theory is accepted as being the only one which embraces all the known facts in cancerous etiology. The biologic conditions, created by irritation in the cells submitted to it, have been studied. The reproductive power of cancerous cells has been proved, and their nutritive requirements demonstrated. De Keating-Hart believes that cancer is produced by cells overcultivated for a long time in the irritated zones of the organism; they are like hothouse plants, which, as a result of slow and prolonged increase of heat and food, acquire, after a variable period, the hereditary characters of overproduction and overfeeding which distinguish them. Ectopy, the invasion of healthy peripheral tissues, is accounted for by the same intensity of multiplication, which breaks down the normal barriers by mechanical pressure. Metastatic effects are due, at the same time, to the increased vitality of the cells easily carried away in the lymph and blood streams, owing to the want of intercellular cohesion peculiar to cancerous formation.

44. **Abnormal Sensations in Pharynx.**—Abnormal sensations in the pharynx, Layton states, are exactly the same as abnormal sensations in the skin, but are brought more to our notice because we are unconscious of the normal sensations there. They may be due to a foreign body, a small local lesion, or an insignificant local lesion associated with a slight general lowering of the resistance of the body. All may lead on to serious disease, and so are well worth attention. Treatment consists in no panacea, but in a careful search for the primary lesion, and a well-balanced consideration of everything concerning the patient's health.

47. **Nasal Catarrh.**—The treatment Wilson has found most useful in cutting short an attack of acute coryza is the following: 1. A single pill of morphin gr. 1/6 made up with a little capsicum and ol. menth. pip. A small dose of nitroglycerin also is advantageous. 2. In two hours 10 grains of aspirin. 3. A hot bath. The following morning, a purgative dose of magnesium sulphate is given to clear away the intestinal contents held back by the morphin. Neither a nasal douche nor a spray should be employed, but an irritant antiseptic ointment containing menthol and salicylic acid, will best fulfil the purpose. A small portion of such an ointment is inserted well up into each nostril, where, if sniffed back, it gives rise to considerable smarting and secretion; it should be applied frequently despite the pain. It will be succeeded by a period of relief, and then the nose can be sprayed repeatedly with a sedative preparation. Despite the pain caused by the menthol-salicylic preparation, no cocain should be employed at all, as it paralyzes the ciliated epithelium and opens the way for fresh infection.

17. **The Adrenal Syndromes.**—Bernard's name is connected with the history of the pathology of the adrenals, and he here compares the histologic findings with the clinical manifestations of excessive or deficient functioning of the adrenals. He calls the syndromes respectively hyperepinephria and hypo-

spinal cord. The young man probably has the same affection although in both the symptoms have been exclusively those of primary spastic spinal paralysis. Eichhorst has previously published a case of multiple sclerosis in a woman and likewise in her son; he thinks this is probably the only case on record in which the same medical man had both mother and child in his charge for multiple cerebrospinal sclerosis and was able to make the post-mortem examination in both. In three other cases of supposed primary spastic spinal paralysis in men microscopic examination of sections of the spinal cord revealed in fact merely the anticipated primary affection of the lateral pyramidal tracts.

61. **Diet and Exercise in Treatment of Weakness of the Muscles.**—Besse refers only to the forms of myasthenia, congenital or acquired, in which the condition has become aggravated by toxic influences either from the results of worry, hurry, unhygienic modes of eating, whims and prejudices in regard to food, abuse of alcohol or tobacco or intestinal auto-intoxication. Persons with this muscular weakness are generally given extra nourishing food which with an unhygienic mode of life only adds to the general auto-intoxication. He gives detailed directions for diet and exercise to influence the condition after the patients have learned to understand their weakness and its causes, and have been trained in rational hygiene and placid living.

Mitteilungen aus den Grenzgebieten der Med. und Chir., Jena

73 *Diagnosis of Mediastinal Disease. F. Siebert.

65. **Empyema in Course of Pneumonia.**—Gerhardt reports four cases of suppuration in the pleura early in the febrile stage of pneumonia, and yet the course of the disease did not seem to be aggravated by the empyema. The pneumonia ran the usual course. No micro-organisms could be found in the scanty pus. In a fifth case the empyema was much more extensive and avirulent pneumococci were found in the pus; convalescence was somewhat retarded in this case. This parapneumonic empyema tends to spontaneous absorption and probably has frequently escaped detection.

66. **Spontaneous Rupture of the Aorta.**—In the case reported a robust young man had been engaged for six years in exceptionally hard physical work and his heart had become hypertrophied from the strain; the abnormally extensive excursions of the diaphragm also cooperated in straining the aorta. The results were a sudden rupture of the aorta in the supposedly unusually sound and strong young man. In the second case necropsy showed rupture of the aorta in a middle-aged man at a point where there evidently had been an old and long healed lesion, probably a dissecting aneurysm of syphilitic origin.

67. **The Functional Importance of the Gall-Bladder.**—Rost's sixty-page article reports comprehensive experimental and anatomic research undertaken to determine to what extent the gall-bladder is necessary to the organism and what effects follow its removal. The absence of the gall-bladder does not seem to affect the metabolism directly but the conditions in regard to the passage of bile into the intestines vary according as the muscle at the papilla acts like a sphincter or not. When there is a long stretch of muscle at the papilla which is able to hold back the bile, [illegible] accumulates above and stretches the duct, making it a reservoir for the bile, like a new gall-bladder. This does not occur when the papilla muscle is incapable of sphincter action. The practical conclusion of the research is that it is wise to leave a portion of the cystic duct when removing the gall-bladder so that it may serve for a new gall-bladder in case the papilla should prove to be "continent."

68. **Tuberculous Gastric Ulcer.**—Gossmann states that he found indications of tuberculosis in 40 per cent. of 5,900 necropsies 1900-1912 at the Munich public hospital. There were signs of tuberculous ulceration in the stomach in only 0.31 per cent. of all the cadavers (0.76 per cent. of the tuberculous cases). A tuberculous ulceration was found in the duodenum near the pylorus in five other cases, and in another group of five there were ulcers both in the stomach and duodenum. There was chronic pulmonary tuberculosis in all the cases, and the stomach or duodenum lesions had not been diagnosed during life. The findings confirm the possibility of infection by way of the blood, the lymph, the mouth or by spreading from adjoining lesions.

70. **Spinal-Cord Tumors.**—Two cases are described in detail in the effort to throw light on the surgical possibilities with tumors originating in the spinal cord or invading it. The tumors in these cases were easily shelled out, but the spinal cord had already been injured to such an extent that most of the symptoms persisted unmodified. In one case, however, the patient was relieved from his agonizing pains by the operation, and had no further pain during the nine months he survived. In the other patient, a man of 70, the tumor was found hidden in the spinal cord; the first symptom over two years before had been a feeling of heat in the left foot, the whole leg finally feeling hot, while the left leg grew weak and finally paralyzed and girdle sensations gradually developed in the upper part of the abdomen and there was difficulty in urinating and finally incontinence of urine and obstinate constipation. The third dorsal vertebra was tender and the region was dull on percussion, but the tumor was found at the second dorsal segment, entirely within the spinal cord. The operation was followed by total flaccid paralysis with anesthesia, but the knee phenomena soon returned. The patient succumbed the fifth day to pneumonia; he had signs of emphysema and bronchitis prior to the operation.

71. **Autoreinfection with Typhoid.**—In Kaspar's case a boy of 10 was left with mild transient periostitis of the left tibia after typhoid. Five years later a similar process developed in the right thigh but healed in a few weeks. Two years later he applied for treatment of a similar process in the right tibia which had come on with a chill and fever. The boy, now 17, was given a test oil breakfast. This causes bile to enter the stomach, and from the bile thus obtained Kaspar was able to cultivate typhoid bacilli, as also from the blood and from the pus in the tibia lesion. The boy had not been exposed to typhoid recently and the case probably must be explained as an autoreinfection, running a very mild course without abdominal symptoms.

72. **The Alleged Pleura Reflex.**—Petersen reports the case of a young woman with symptoms of an abscess in the lung requiring operative treatment. A small amount of pus was aspirated from the pleura but the patient collapsed when the thermocautery was applied under local anesthesia. She revived readily but a pneumothorax was left and the fever kept persistently high. A week later several punctures were made but no pus could be found. The sputum showed traces of blood and the patient collapsed anew with all the signs that have been described as the pleura reflex, and she could not be resuscitated. The necropsy findings indicated that the trouble was due to injury by the puncture needle of some blood-vessel. This had permitted the entrance of air during inspiration and fatal air embolism was the result. Petersen is convinced that the so-called pleura reflex is probably in many cases in fact an air embolism.

73. **Disease in the Mediastinum.**—Siebert found on vertical orthodiagraphy that the diameter of the aorta averaged 2.6 cm. in twenty-six normal adults of all ages between 46 and 55, ranging from 2 to 3 cm. In seven others with signs of dilatation of the heart or vessel trouble the range was from 3.4 to 4.2 cm. The early diagnosis of beginning sclerosis or syphilitic dilatation of the aorta is thus possible by ascertain-

ing the diameter of the vessel. He also reports a case of nearly complete obliteration of the superior vena cava with development of collateral circulation between the superior and inferior vena cava, similar to a case published by Osler some years ago. Both patients had the characteristic sensation of constriction in the chest.

79 *Complete Rupture of the Uterus. O. Nebesky.
80 Lithopedion Carried in the Mesentery for Twenty Years. L. Biener.

75. **Serodiagnosis of Pregnancy.**—Wolff describes his experiments with Abderhalden's method, resulting in failure at first until he learned from Abderhalden himself the exact technic for preparing the placenta. He concludes that the method shows pregnancy in its very beginning if the placenta is washed until it is absolutely free of blood and does not react with ninhydrin. Abderhalden's directions must be minutely followed. The serum to be used must not be allowed to stand more than four or five hours. The reaction is of special value for differential diagnosis between pregnancy and tumors. The test is not suited for general practice but has great value in hospitals where it can be performed often enough to ensure exact technic.

79. **Treatment of Complete Rupture of Uterus.**—Nebesky gives statistics and describes four cases to show the necessity for immediate operation for rupture of the uterus and the inadequacy of conservative treatment.

92 *Infusion of Blood in Treatment of Severe Anemia. Windesheim.
93 Radium in Therapeutics. F. Herrmann.

81. **Congenital Steeple Skull.**—Küttner explains this deformity as the result of the growing together of the bones of the skull before the normal time for ossification. In two cases he has encountered this occurred before the child was born, and the deformity has persisted unmodified. The children are now over a year old. The girl has several other deformities, cleft palate, etc. Meltzer found the steeple skull at birth only in one of twenty blind children with steeple skull. Twelve of the other children had an unusually tall skull at birth, but the actual deformity did not develop until the children were 1 to 6 years old; seven other children were normal at birth, and the skull assumed the steeple shape between the ages of 3 months and 3 years. Küttner has found in the literature only one case resembling the first he reports, with extreme exophthalmos from the shallowness of the orbits. The danger to the eyes is generally from atrophy of the optic nerve from compression. Decompressive trephining is indicated to prevent choked disk and atrophy; puncture, if there is an excess of fluid in the skull. Schloffer has proposed to enlarge the bony canal for the optic nerve in case of steeple skull, and he has done this in two clinical cases. One operation was done quite recently; the other patient seems to be somewhat improved. Of course, for children, this serious operation would be considered only after failure of a decompressive operation.

83. **Electric Influencing of the Leukocyte Picture.**—This is only the first instalment of Veraguth's article, but it states that the application of electricity in the cases reported was able to restore the abnormal leukocyte picture to approximately normal in a remarkably short time. The red corpuscles and a normal leukocyte blood-picture do not seem to be influenced, but an abnormal leukocyte picture changes at once for the better, as he shows by the blood-count in a case of secondary anemia, in three of lymphocytosis with exophthalmic goiter, six of lymphocytosis of other origins, two of myeloid leukemia, one of Werlhof's disease and two healthy controls. The electric current was of low tension and low intensity, and the sittings ranged from five to thirty minutes in length. In four cases of lymphocytosis the number of leukocytes dropped from 13,600 to 6,200; from 8,200 to 5,200; from 11,600 to 8,800 and from 12,600 to 11,200 under a fifteen-minute exposure, the reduction thus ranging from 1,400 to 7,400, while the proportion of lymphocytes was reduced by 4 up to 18 per cent. In one of the three exophthalmic goiter cases the leukocytes numbered 13,600, but dropped after a thirty-minute exposure to 5,900; two days later the leukocytes numbered 6,600, and dropped to 5,100 under a twenty-five minute exposure. The lymphocytes dropped during the two exposures from 43 to 31.5 per cent. and from 49.5 to 41 per cent. No further details as to technic are given in this instalment of the article.

87. **Technic for Tonsillectomy.**—Trautmann insists that the tonsil capsule should be removed with it, that is, the sheet of connective-tissue that encloses the tonsil on the outside. The portion of the tonsil toward the mouth extends beyond the capsule, which only covers the side. The front of the tonsil is covered with what he calls the prepuce; it shows up when the root of the tongue is depressed with a spatula. The anterior pillar of the soft palate starts from the tongue like a flag-staff and the prepuce spreads from it above like a flag on its standard. He gives several illustrations to show conditions and the advantages of obtaining access to the tonsil by a curving incision through this prepuce; this exposes the tonsil and also its capsule and permits the whole to be easily shelled out with the finger or a blunt instrument. He warns expressly against using a cutting instrument. The tonsil is taken out through the incision, not directly into the mouth; by this means all danger is avoided of injuring the veins. The vessels severed in the operation retract at once and as they slip back into the stout muscles forming the tonsil recess they become compressed so that there is no danger of hemorrhage. If there should be hemorrhage the tonsil cavity being so amply exposed by this technic renders it a comparatively easy matter to arrest the bleeding.

89. **The Specificity of the Abderhalden Protective Ferments.**—Fuchs reports experiments which confirmed the absolutely specific nature for the organ involved of the ferments demonstrated by the Abderhalden technic. The serum of rabbits treated with human kidney tissue was able to digest kidney tissue in eighty-eight hours while it did not digest liver tissue, and vice versa. He has also confirmed in further research the findings of others in regard to the specific digestion of testicle tissue by the serum of men with dementia praecox, and of ovary tissue in women, and never the reverse. Also the total absence of any digesting property for the ovaries or testicles in the serum of patients with depressive mania, and, further, the positive reaction in cancer cases. The reaction proved specific for the organ whether derived from human beings, calves or laboratory animals, and it was equally pronounced irrespective of the species.

90. **Serotherapy of Tetanus.**—Weber relates two cases to show the importance of giving antitetanus serum as early as possible, and keeping it up until the spasms have become much mitigated. Children seem to bear a large total dosage without harm. The first patient was a boy of 13, and he recovered under fourteen injections of the antitetanus serum, a total of 1,400 serum units.

91. **Examination of the Urine.**—Röhl uses the *two-glass* method and states that it frequently happens that the urine may seem perfectly limpid at first, but if it is set aside for a few minutes it becomes slightly turbid. Consequently he advises waiting for fifteen minutes up to an hour before passing final judgment on the urine.

92. **Treatment of Pernicious Anemia.**—Windesheim states that prompt improvement followed intragluteal injection of 10 c.c. of still warm human blood at intervals of ten or fifteen days. The patient was a woman of 52, with signs of pernicious anemia, entire loss of appetite and repeated vomiting. Seven injections of the blood were made in the course of four months, and the blood regained nearly its normal composition and the patient now feels well and comparatively strong.

102 The Work of the Council on Pharmacy and Chemistry of the A. M. A. W. Heubner.

94. **Lime in Therapeutics.**—Von den Velden limits his discussion of this subject here to the action of calcium salts on the endothelium of the vessels and on the coagulation of the blood. He gave patients 1 gm. tablets of calcium lactate up to a total dosage of 4 or 6 gm. a day. To a few others he gave calcium chlorid 0.5 gm. three times a day. In a few cases he gave the lime by intravenous injections of a 5 per cent. solution of calcium chlorid. His experience has demonstrated that the calcium enhances the coagulating power of the blood and also renders the morbidly permeable vessel walls less permeable. The latter effect is strikingly evident in hemorrhagic affections, such as scorbutus; the calcium renders the vessel walls less porous. This hemostatic effect therefore can be anticipated only in case of bleeding by diapedesis. It is unfortunate that the absorption of the calcium salts depends on a variety of factors, especially on good gastric secretion and on the absence of fermentation acids in the intestine. He detected the abnormal permeability of the vessels responsible for the rebellious scorbutus hemorrhages in one case by applying a cupping glass for five minutes. The vacuum glass drew blood just the same after two weeks of the ordinary measures. Then he gave the man 3 gm. a day of calcium lactate for five days after which the cupping glass no longer drew blood, and complete recovery followed in three weeks of the same treatment. He also found calcium lactate useful in two cases of iodin poisoning from a course of potassium iodid. A further useful application of the calcium lactate is in curing the cutaneous manifestations of anaphylaxis. In pleurisy with effusion the fact that the calcium renders the vessel walls less pervious has an unfavorable side, as this checks absorption. The calcium is indicated, therefore, only when the effusion constantly recurs after puncture. When the walls of the pleura are severely modified by chronic inflammation, the calcium will naturally have no effect. He found that animals developed cachexia when given calcium salts over a long period. In fifteen cases of hemorrhagic nephritis the results of the calcium medication were conflicting. No pronounced favorable results were obtained in any case and the condition was aggravated in some.

98. **Tuberculin Treatment of Tuberculosis in Children.**—Eckert warns that the tuberculin may arouse slumbering tubercle bacilli and drive them out of their latent focus into the blood stream. This would be disastrous as children have less resisting powers than adults in respect to tubercle bacilli. The only technic for tuberculin treatment for children is to keep the doses so small that no reaction is elicited in the focus. The aim is not to cure the tuberculosis but to enhance the resisting powers so that the child single-handed can conquer the disease.

99. **Occult Blood in Stools on Gastric-Ulcer Diet.**—Queisser found blood with the Weber test in 20 per cent. of forty persons free from gastro-intestinal ulceration but fed with the Lenhartz gastric-ulcer diet. The chopped meat in this diet was evidently responsible for the positive findings.

100. **Warning Against Catgut for Suturing Abdominal Fascia.**—Müller used catgut to suture the abdominal wall after removing an ovarian cyst in a woman who proved to be coming down with typhoid. The wound healed by primary intention, but the ninth day it opened its entire length with eventration of most of the intestine. The catgut had evidently been absorbed too soon; the fever may have hastened the absorption. The woman, a Chinese, recovered with no signs of peritonitis.

107 Present Status of Mercury in Therapeutics. (Quecksilbertherapie.) M. Joseph.

103. **Gastric Achylia.**—Albu has encountered seven families in which a parent and child presented evidence of an inherited tendency to gastric achylia. He calls this type the aplastic form as it is evidently the result of defective development. It is one of the most characteristic signs of the neuropathic constitution. He warns that this aplastic gastric achylia should be suspected when older children exhibit chronic disturbances in digestion and nutrition. He urges pediatrists to make a special physiologic analysis of such cases with the more modern means of investigation, testing separately the functioning of the stomach, pancreas and intestine. This form of achylia may be regarded as on the same clinical plane as orthostatic albuminuria. The achylia may manifest itself by acute disturbances which in turn may yield to normal conditions. He has had five cases of this kind. One patient, a nervous young merchant, has had three such attacks in the last two years; periods of hyperchlorhydria have also been observed during this period. The trouble is probably a transient exhaustion of a functionally weak gastric mucosa. Such patients do particularly well on a purely vegetable diet, the food all served in the most finely divided form in purées. By dropping meat from the diet for four or six weeks, the bacterial flora in the intestines is transformed. Yoghurt may prove useful; sweet milk is generally badly borne. Cutting out the meat from the diet is particularly beneficial when the pancreas secretion is also below par; fat should also be restricted in this case. Veal and chicken meat in the form of a jelly are appetizing additions to the diet. Hydrochloric acid and pancreas preparations may be needed symptomatically and may have to be kept up for years, suspending them for a time every month.

104. **Treatment of Obesity.**—Kimmerle reports four cases in which a modified Karell course of dieting answered the purpose most admirably. One patient lost 13.6 kilograms in six weeks under it, and by keeping up the restrictions for the year, had her weight further reduced by 42.2 kgm., nearly 109 pounds. The first five days only 200 c.c. of milk was allowed, the patient keeping in bed. Then small amounts of meat and bread were permitted and after six weeks the diet was regulated to keep below 10.5 gm. nitrogen and later below 12 gm. nitrogen. She did not suffer materially from thirst or hunger, and none of the patients showed any injury from this low nitrogen intake.

113 Experimental Cancer Research. F. Keysser.

108 to 112. Radium in Treatment of Malignant Tumors.—Radium was the main topic of interest at the recent German "Naturforscher Congress," which was held at Vienna this year. The clinicians connected with the university of Vienna have more radium at their disposal than any one else, the faculty now having 1.5 gm. of the radium element. Riehl reported the results attained with radium treatment of cancer at the public hospital. Wertheim the results in treatment of uterine cancer, Peham the results in the gynecology clinic, others presenting a report on the experiences with radium in fifty-three cancer cases at von Eiselsberg's surgical clinic, while Dautwitz reported from St. Joachimsthal his results with twenty-one radium capsules as applied in hundreds of cases of various surgical and dermatologic affections. This testimony shows that the wave of overenthusiasm for radium treatment of malignant disease is already subsiding, and a more rational judgment is taking its place, and the possible dangers in its use are becoming recognized.

Riehl emphasized the importance of uniform terms and standards for comparison of the strength and effects of the radium. He ascribes the action of radium on cancer tissue to the fact that the cancer cells, being degenerated, succumb more readily to the rays than sound tissue. In time and with sufficient dosage the sound tissue is influenced also in the same way. He never noticed anything that indicated an indirect action from the radium on adjoining or remote tissues, lymph-nodes, etc. His experimental research demonstrated that the exposures affected the blood; small doses induced leukocytosis, while large doses reduced the number of leukocytes until they disappeared entirely from the blood. In small animals the spleen also disappeared and other injuries were noted, demonstrating the possibility of serious damage in the clinic from prolonged and intense exposure to radium. Some of his patients exhibited vertigo, vomiting, agitation, bad pulse and collapse after intensive radium exposures, suggesting that certain organs or the entire organism had suffered under the influence of the rays. His experience warns further that inadequate doses and too brief exposures have an actual stimulating action on the malignant disease.

Wertheim's experience has convinced him that in the cases which responded favorably to the radium treatment, ordinary measures would have answered the same purpose equally well. Some of his patients evidently suffered from the influence of the radium, becoming emaciated and weak, with weakness of the heart, headaches, sleeplessness, disturbance in bladder and intestine functioning and local pains. It is his impression that preceding radium exposures render more difficult the removal of the growth later.

The reports from the Eiselsberg clinic state that removal of the cancer should be the rule, but that radium or the Roentgen rays are indispensable after the operation to act on any cancer cells that have escaped the knife.

119 *Tuberculous Gastric Tumor. (Tubercolosi dello stomaco a forma neoplastica.) O. Ortali.

119. Tuberculous Tumor in the Stomach.—Ortali's patient was a farmer of 52 who had had stomach trouble for six months, eructations, pain an hour or two after eating, and vomiting every two or three days soon after eating. No blood had been noticed in the stools or vomit. There was slight evening temperature, no cough or night sweats, but diarrhea and constipation alternated and the man grew very thin. Lactic acid but no free hydrochloric acid was found in the stomach content and the stomach was opened on suspicion of cancer. The pylorus region was found the seat of a hard tumor studded with granulations. Gastro-enterostomy relieved the patient of his disturbances, but he succumbed two months later to peritonitis. Ortali knows of only twenty-four cases on record of this tumor form of tuberculosis of the stomach.

123. Chronic Appendicitis Without Acute Phase.—Bolognesi insists that appendicitis may develop with merely slight disturbances, nothing more than vague gastro-intestinal pains, dyspepsia and constipation. In time, however, the chronic inflammation entails changes in the appendix similar in every respect to those of ordinary appendicitis with one or several acute phases. He found this to be the case in four of twenty cases of chronic appendicitis reported; nothing had been known of an acute attack in any instance.

134 Means to Reduce Infant Mortality. V. Varshavsky.

125. Hemorrhage from the Uterus in the Newborn.—Gogitidze does not consider the hemorrhage in infants as a pathological occurrence because the uterus of the newborn undergoes a reaction followed by enlargement of this organ, hyperemia and hemorrhages. In some cases the physiological hyperemia is intense, ending in hemorrhage. This condition must be differentiated from precocious menstruation which is a periodical discharge of blood in very young children, accompanied by premature development of the sexual organs. The metrorrhagia does not occur periodically, usually lasts about forty-eight hours, and disappears without treatment. In his four cases there was no history of sepsis, ulcers, melena, endometritis, or any gastro-intestinal disorder. (The views of Gogitidze are criticized by Joukovsky in an article published later in *Pediatria*, p. 474.) Joukovsky regards the hemorrhage as a pathologic phenomenon, stating that it never occurs in healthy children, only in those suffering from gastro-intestinal disorders. He adds that it is not rare by any means; he has observed it in more than fifty cases.

127. Acute Pneumonia in Children.—As the views in regard to classification of pneumonia in children are not the with different authors. Sokoloff gives a review of the li ature on this question and his own views based on rich clinical and pathologic material. In the diagnosis of pneumonia, in each case, the lobe or lobule should be recorded, on which side, then the character of the exudation (catarrhal, fibrinous or both), finally the etiologic factor (diplococcus, streptococcus, staphylococcus, influenza, measles, pneumonia, etc.). When all the data are thus recorded a complete idea of the morbid process may be gained; the course and prognosis can then be outlined, etc. In other words, the whole character of the disease can be easily determined and understood if the above points are uniformly recorded.

128. **Tuberculosis of Pulmonary Lymph-Nodes and Spine Mistaken for Croup.**—Symptoms of stenosis of air passages may be caused by pressure of tuberculous bronchial lymph-nodes, and it is very important to differentiate stenosis of this kind due to outside pressure and not mistake it for croup. Michaelovitch discusses this question from various points of view, including the etiologic, bacteriologic, pathologic, anatomic, clinical, the course, etc. He comes to the conclusion that frequently, especially when the case is urgent, the differential diagnosis can be partly guessed from the general appearance of the patient, his history, percussion, auscultation, etc., but mainly from the fact that in stenosis from tuberculosis the dyspnea or stenotic respiration occurs during both inspiration and expiration, while in croup it is inspiratory alone. The stridor may increase from crying, coughing, etc., and closely resemble that in laryngeal diphtheria. As it is impossible in an urgent case to exclude diphtheria, he recommends as a prophylactic measure intubation and injection of antitoxin. Later, exact differentiation can be made through proper clinical, bacteriologic and especially roentgen-ray examinations.

129. **Specific Skin Reaction to Mustard in Children with the Exudative Diathesis.**—Rachmilevitch has been studying in children the so-called exudative diathesis with which there are lesions in the skin, mucous membranes or lymphatic tissues. Here belong seborrhea, intertrigo, recurring bronchitis, asthma, lymphatic states (enlarged tonsils, enlarged spleen), etc. When the symptoms are not pronounced, it is hard or almost impossible to diagnose the existing tendency, the exudative diathesis. In these dubious cases Rachmilevitch found a new method of diagnosis. The skin of the arm, for instance, is scarified, and a paste containing mustard is rubbed into the scarifications, and bandaged. While healthy children will show probably more or less redness on the places of irritation, children with the morbid diathesis will show within half an hour after the irritation a white blister surrounded by a hyperemic area which persists for fourteen or eighteen days. Serum in the form of small drops will appear, not coagulating before two hours. All these phenomena, the formation of the vesicle, the serous exudation, the retarded coagulation, constitute a positive reaction. This reaction occurs not only in children with clearly developed symptoms of the exudative diathesis, but also in those in whom the symptoms are hardly manifest, or in whom only one sign is present. Children who are perfectly healthy, or who do not show any signs of the exudative diathesis, give a negative reaction. From study of 100 cases Rachmilevitch comes to the conclusion that the described test is a very reliable means for determining occult types of the exudative diathesis. Czerny has confirmed the differential importance of this test, he states in conclusion.

130. **Chronic Diphtheria Bacilli Carriers.**—Lunin found that in 708 cases of diphtheria only 1.1 per cent. gave rise to "return cases." The patients were discharged after three bacteriologic examinations of the mucus from the throat and nose had given negative results. He also found that the bacilli that occur in healthy people or remain unusually long in those who have had an attack of diphtheria, are not virulent, and are thus harmless. They may accordingly be sent home or left among other patients; the only precaution he recommends is to gargle the throat and clean the teeth.

132. **The Thyroid in Scarlet Fever.**—Gregor studied twenty-one cases of scarlet fever in regard to changes caused by this disease in the thyroid gland. It was studied at various stages of the disease (second day to twenty-seventh day), and the findings were compared with those found in the thyroid gland during catarrhal pneumonia, chronic enterocolitis, measles, etc. Böhmer's hematoxylin and the Van Giesen stain were used. The findings showed that the thyroid is considerably involved in scarlet fever, especially the vessels and the parenchyma itself; the colloid substance decreases according to the duration of the disease. He frequently found numerous bacteria emboli, which speaks for bacterial thyroiditis in scarlet fever superposed on a toxic irritation. The thyroiditis may entail later actual thyroid disease, such as exophthalmic goiter. The clinical manifestations of the scarlatinal thyroiditis are not known, as it is hard to trace them in children.

133. **Case of Leiner's Desquamating Erythrodermia.**—Zvenigorodsky differentiates this affection from similar skin lesions in infants, defining it as a general dermatosis with diffuse reddening of epidermis and formation of scales and scabs. No symptoms of Czerny's exudative diathesis were apparent in the case reported. The peculiar feature of this disease is the presence of gastro-intestinal disorders with breast-feeding. Auto-intoxication is looked on as the cause, as in his case the mother had suppurative mastitis. As this healed the gastro-intestinal disturbance in the child, as well as his skin disease, disappeared.

139 Another Case of Acute Dilatation of the Stomach. (Akut ventrikelektasi.) Bretteville-Jensen.
140 Ferric-Chlorid Urine Reaction and Impending Diabetic Coma. (Om den Gerhardt'ske jernkloridreaktion, og om hvilke holdepunkter man har til bedømmelse av faren for at der skal indtræde et coma diabeticum.) H. C. Geelmuyden.

137. **Osteomalacia.**—Brandt describes a case of severe osteomalacia in a ii-para of 32. Symptoms were first noticed two years after her first child was born; her limbs seemed weak and the condition became aggravated during her second pregnancy and later; by the sixth year she presented the extreme type of osteomalacia. The ovaries were then removed and slight improvement was at once evident, but the patient died in a few days; necropsy was not permitted. In a second case the osteomalacia developed during a first pregnancy and grew worse during a second and third pregnancy, letting up in the intervals. Supravaginal amputation of the uterus was done a month before term and the woman seemed to have quite recovered from the osteomalacia when she left the hospital seven weeks later. Brandt states that he knows of only five other cases of osteomalacia that have been published in Norway. He analyzes the total seven and remarks that ovariectomy must be regarded as the specific treatment for it.

141 *End-Results of Treatment of Genital Prolapse. S. A. Gammeltoft.

141. **Genital Prolapse.**—Gammeltoft was able to learn the history to date of 132 of 150 patients who were given operative treatment for genital prolapse since 1900. Six of the total patients died in connection with the operation, and six have died since. The ultimate outcome to date is thus known in 127 cases; conditions are entirely satisfactory in eighty-one of the patients; seventeen patients have no subjective disturbances but the anatomic condition is not perfect, or else the anatomic condition is satisfactory but there are slight subjective symptoms. The prolapse recurred in twenty-four other cases. In three other cases conditions are excellent in every respect except that the cervix has become hypertrophied. In the two remaining cases the prolapse recurred after a severe fall or difficult forceps delivery. In regard to the operative technic, he says that scarcely any condition requires individualizing to such an extent; the combined vaginal and abdominal method is certainly great progress.
